water level, being connected to the safe by a pipe or way having a stop cock applied thereto.—Patent completed.

2406 P. N. J. NARCISSE, Paris. Feeding botien. Dated July 31. 1868.

The feeding apparatus is applied to act automatically to fixed boilers. Two cylindrical chambers or receivers are maintained or supported at their upper parts by a bent double lever oscillating in two gudgeons, placed one on each side of a vertical column. At their lower parts, these two receivers each carry a socket with two compartments, articulated by means of two stuffing boxes to two square tubes or right angle bends acrewed to the extremities of two tubular arms fixed on the valves on either side of the before-mentioned column, these arms forming with the bent lever a parallelogram which always keeps the receivers in a vertical position. One of the two compartments of the sockets, that which receives the steam, is prolonged upwards within the receivers to nearly their tops by a tube or dip pipe. The other compartment, which receives the water, opens at once into the bottoms of the same compartments. The two valves fixed to the tubular arms oscillate in two sockets fixed on the square base of the column, which sockets have double compartments and four orifices; they distribute the water and steam separately and alternately in the two receivers. These two lower communicating with the dome of the boiler, and giving entrance to the steam into the apparatus, and the two upper allowing the escape of the steam into the atmosphere, or preferably into the feed water reservoir.—Patent completed.

2407 B. Sharpe, Hanwell-park. Shipe and batteries.

atmosphere, or preferably into the feed water reservoir.—
Patent completed.

2407 B. Sharpe, Hanwell-park. Ships and batteries.
Dated July 31, 1868.

In mounting great guns, instead of the usual gun carriages, two guns are attached to the opposite ends of a framework of twood or metal, in such a manner as will permit them to revolve in a vertical direction when secured to a ber of metal or wood passing between, the whole of which being also made to move in a horizontal direction, on wheels, attached to a framework of wood or metal, which framework in the case of ships, supports a deck, and, in the case of batteries, a protective covering of wood, metal, and other substances. The framework of the vertical motion has at other times the axis on which it revolves supported by another framework, resting on a centre, and turning horizontally on this centre, and on wheels placed under it, while it is kept in position by a lateral framework revolving on wheels and supporting a deck or covering. The framework for the vertical motion is made of a sufficient length to enable one of the guns at one point of the revolution to appear at such a height above the deck or covering, either for protection or for being fired with a sufficient degree of depression, and at another point as will allow both of the guns being placed under the deck or covering, either for protection or for being loaded, the aperture in the deck or covering through which the guns alternately appear and disappear, being then closed by a covering of wood, metal, or other substance, with a port on hinges attached to the vertical framework, and revolving with it.—Patent completed.

2408 G. D. Kittok and P. Brotherhood, Clerkenwell. Cooling fluids. Dated July 31, 1868.

framework, and revolving with it.—Patent completed.
2408 G. D. KITTOR and P. BROTHERHOOD, Clerkenwell.
Cooling Ruids. Dated July 31, 1868.

The object sought to be attained by this invention is to secure a great length of run for the fluids, so that the matter to be cooled, heated, or tempered is kept for a long time exposed to the influence of the liquid which acts upon it, and, at the same time, to provide facilities for cleansing the tubes. The patentees provide a number of tubes, and enclose each of them within another tube of larger diameter, the inner tubes being intended to receive the hot matter to be cooled, and the annular space between being intended to receive the water used for cooling. The double tubes are arranged in rows, tier above tier, and form communications. The wort or liquid to be cooled enters the first of the top inner tubes, and circulates backwards and forwards and downwards through all the tubes in succession to the lowest row, whence, after

completing its circulation, it finally issues,-Patent abo

2409 H. MOULE, Dorset. Feeding furnaces. Dated July 31.

2409 H. Moule, Dorset, Feeding furnaces. Dated July 31, 1888.

This consists of a grate (somewhat like an ordinary grate, but with the bottom removed) fitted upon a watertight reservoir or cistern of segmental form, in cross section, and of a width corresponding with that of the grate. This cistern constitutes the hopper for receiving into the liquid matter which it contains the coals, coke, shale, or other solid matter to be burned. The cistern or reservoir is conveniently made of cast iron with a flange at back to allow of the attachment of the grate thereto, and with ribe or corrugations to facilitate the traverse of the solid fuel through the cistern. In the line of the axis of the curved cistern is mounted a swinging propeller formed of pronga, arranged all in the same plane, and projecting from a transverse shaft mounted in suitable bearings within and external of the cistern. The propeller is intended to sweep over the bottom of the cistern with coal. The propeller is first raised on its trunnions, and the coal being thrown in the propeller is let down in rear of the charge, and, being pressed upon it, the fuel will be caused to slittle forward and rise to the required level in the grate. This being effected, the upper surface of the fuel is ignited in the ordinary manner. Waste water is poured into the cistern, upon or with the coals, and is kept up to a proper level in the cistern by additions thereto from time to time as it is evaporated. The coal or coke as it is pressed up into the firejace by the movement of the propeller will be coated and impregnated with the liquid, which, on coming in contact with the heat, will be reduced to its constituent gases, and, being then consumed, will add to the intensity of the fire. As the fuel burns away, the plunger is caused to press upward a fresh supply from below—Patent completed.

2410 R. E. DRINHAUS, Strand. Surgical instruments.

from below.—Patent completed.

2410 R. E. DRINHAUS, Strand. Surgical instruments.
Dated July 31, 1868.

The instrument consists of a metal disc, from the face of which projects a number of needles of equal length. It is enclosed in a casing provided with a hollow stem, through which passes a spiral spring; the spring terminates in a handle which projects from the end of the stem. The operation of the instrument is as follows:—Having removed the needle cover the open end of the instrument is applied on the skin at the part required. The handle is then drawn out from the stem until the spring is sufficiently extended, when the handle is suddenly released. The reaction of the spring will project the disc and needles forward, causing the latter to slightly puncture the skin where applied. The epidermis thus prepared will be ready for the application of oil or linament, which is painted over the punctured part by means of a feather or soft brush.—Patent abandoned.

2411 W. W. LYMINGTON, Somerset. Cutting up sugar.

is painted over the punctured part by means of a feather or soft brush.—Patent abandoned.

2411 W. W. Lymington, Somerset. Cutting up sugar. Dated July 31, 1868.

The apparatus is composed of standards, connected to form a bearing for a driving shaft. Below this driving shaft, and between the standards, is placed a knife, fixed to a block working in guides, having an up and down motion imparted to it. Below the knife, and opposed to it, is placed a second knife, also fitted to work in grooves, by means of a transverse plate passing through the knife block. This transverse plate works in grooves in the standards, and has an inclined upper surface, which is received in a corresponding groove in the knife block. In front of the standards, and at one end of the machine, is placed a tray mounted on a framing, upon which the tittlers or loaves of sugar are placed. Beneath this tray is an endless chain passing round pulleys, mounted near either end, which chain is provided with two or more fingers, projecting upwards through a longitudinal slot in the bottom of the tray, which, on the chain pulleys being rotated, move in the direction of the vertical knives, carrying with them the loaf or loaves placed on the tray. When the lower knife is in its lowest position, and the cupper knife is raised, a loaf of sugar is placed on the tray in front of a finger or feeder, its base projecting over the edge of the lower knife on which it rests. At each revolution, of the driving shaft, the upper knife descends, detaching a slice or disc from the end of the loaf, the latteneng advanced by the finger the thickness of a slice at each revolution. As the diameter of the loaf decreases, the lower knife is caused to rise by means of the vertical shaft and inclined slide before mentioned, so as to constantly maintain the upper side of the loaf in a horizontal position for insuring a uniform penetration of the upper knife.—Patent abandoned.

2412 A. F. Leale, Soho. Boilers. Dated July 31, 1868.

2412 A. F. LEALE, Soho. Boilers. Dated July 31, 1868. The patentee proposes to prevent incrustation in boilers by placing in the said apparatus any fibrous substance, such as tow or hemp. To the outside of the boiler a pipe of large diameter is connected, one end of which is fixed underneath the boiler, near one end; the other end of the pipe is fixed near the opposite end of the boiler at the level of the water; the pipe will thus assume a slanting position. Within this pipe is a perforated or wire gauze pipe filled loosely with fibrous material. As crew cap secures the same steam-tight in the outer pipe. There are cocks fitted for shutting off the communication with the inside of the boiler when it is required to remove the fibrous material, which can be done, and fresh fibrous material be replaced without stopping the working of the boiler.—Patent abandoned.

2413 H. MORITZ and J. Devented the contraction of the boiler.

2413 H. MORITZ and J. REINACH, Berlin. Planing files.

2413 H. MORITZ and J. REINACH, Berlin. Planing files. Dated July 31, 1868.

A planing cutter is firmly piaced in a stock on the upper part of a frame, and above the file to be planed; the file is conducted beneath it in a curved path, so as to bring the varying level or taper of the file under the cutter. In the frame, parallel rocking bars are set on axles, and their ends meet endway underneath the plane. The elevation of these rockers is regulated by a crank and shaft turning a vertical bevel wheel gearing with a horizontal bevel, actuating a vertical ecrew shaft which elevates and depresses the rockers, above which the sliding carrier gripping the file is set, such carrier being moved with a reciprocating motion, after the manner of an ordinary metal planing machine. The gripper consists of two claws or clamps compressed together or widened by a screw so as to enable them to grasp the varying lateral taper of the file. The grippers are caused to rise and fall to suit the thickness of the file by ordinary adjusting screws. The requisite pressure of the plane steel upon the file is produced by a lever pressing upon a sliding holder in the stock.—Patent completed.

2414 H. MORITZ and J. REINACH, Berlin. Cutting fles.
Dated July 31, 1868.
In this machine the hammer or cutter is set on an axis which oscillates so as to cause the hammer to rise and fall by a tappet motion and cut the file which travels underneath the cutter backwards and forwards, so as to effect the cross or angular reversed cuts or grooves in the file.—Patent completed.

2415 G. HARVEY, Birmingham. Collar holder. Dated July 31, 1868. This consists in constructing metallic holders of two This consists in constructing metallic bolders of two parts, the back forming an open loop for passing over and riding on a button or stud; it is secured on the back of gentlemen's neckties, and may be applied or removed at pleasure by the loop at the back being passed over the stud or button of the shirt collar. The back loop is connected to an ornamental front bar capable of receiving settings of precious stones, or other ornamental devices by means of a hinge joint.—Patent abandoned.

2416 A. TAYLOR, Birmingham. Brooch fastener. Dated

2416 A. TAYLOR, Birmingham. Brooch fastener. Dasca July 31, 1868.

The patentee purposes confining within a spring hook the brooch pin point; it passes down on the side of the free end of a guide bar, and pressing on the exterior of a spring hook, which, yielding to pressure, allows the free end of the pin to pass down, when the force of a spring in connection with the hook forces the hook outward until it is in contact with the guide bar, when the pin will be secured. To free the same, the pin has again, in like manner, to be pressed against the guide bar and the curved end of the hook, which will yield, and permit the end of the pin to be freed in order that the brooch may be removed at the discretion of the user.—Patent abandoned.

2417 J. HEATON, Derby. Treating cast from. Dated ply 31, 1863.

July 31, 1868.

The patentee claims the production of refined or of purified cast from by the employment of nitrate of soda or nitrate of potash, or mixtures of the same, either alone or in conjunction with a blast.—Patent completed.

2418 J. HEATON, Derby. Producing steel. Dated July 31,

1868.

This relates to the production of steel, and consists in the employment for such purpose of the purified or refined pig or cast iron, or the combination of iron and carbon, such as results from the action of nitrate of soda or nitrate of potash upon cast iron, when in a moiten state, either alone, or in conjunction with a blast, and contained in a converter, together with metallic iron, such as sponge, scrap, bar, or other form of metallic or malleable iron.—Patent completed.

Patent completed.

2419 T. Hunt, Hammersmith. Breech-loaders. Dated July 29, 1868.

The gun berrel is made in two separate parts; one consists of so much of the breech end as will contain the charge and shot, and the other is the remainder of the barrel. The outside of the "firing chamber," towards its rear end, is screwed to fit into a pivot or trunnion nut, the trunnions of which work in two check plates, one on each side, secured to the rear of the barrel and the stock. The object of the screw is to insert and release the front end of the "firing chamber," from the rear end of the barrel, and the trunnions enable the firing chamber, when so released, to partly revolve vertically, so that its open end may be elevated clear above the barrel, sufficiently to enable the empty cartridge case to be removed and the gun reloaded. By a side pressure of the finger or thumb on the wing or projection, attached to the front end of the firing chamber, the latter makes about one-third of a revolution, and the pitch of the screw is so made that the movement is sufficient to release or insert it from the barrel, after which the rear end of the firing chamber is depressed, until it disengages the cartridge hammer, which, being actuated by a spring, and having a projecting pin, which enters the circular hole, in the end of the firing chamber, strikes out the empty cartridge; the hammer is then withdrawn, a new charge put in, and the front end of the firing chamber inserted into the guide cylinder, and, by means of the screw, effectually tightened up to prevent any escape of the explosive gases past the point of junction.—Patent abandoned.

doned.

2420 J. E. OUTRIDGE, Isle of Wight. Stide calres. Dated August 1, 1868.

This relates to a peculiar construction and arrangement of mechanism, whereby the pressure of steam and vacuum is removed from slide valves, and their free working obtained without friction upon their faces. This is accomplished by attaching to the ordinary valve box of a steam engine, an apparatus, consisting of one, two, or more castings, each casting containing ports or passages for the inlet or outlet of the steam. The faces of the castings which contain the norts or massages are opposite to each other, and or outlet of the steam. The faces of the castings which contain the ports or passages are opposite to each other, and may be fixed parallel to each other, or otherwise. Between these faces, a single or double slide is placed, each of which has an aperture in it, whereby the communication from passage to passage is perfectly free. When a double slide is employed, blades of brass or other metal are placed upon the part or parts of the slide exposed to the steam, to prevent a passage between the two slides or parts. A lever affixed to the slide rod will keep the valve or valves to their faces.—Patent completed.

races.—Fatent completed.

2421 C. J. L. Nicholson. Thredneedle-street. Preserving food. Dated August 1, 1868.

This consists in fitting to the tops of cans for preserving food a plate, having a screw passed through it; a disc of elastic material is placed under this plate, and a guide pin depend therefrom. This pin serves to guide a second plate, placed inside the can, and which the screw draws up against the inside of the can and elastic disc, in order to make a close joint.—Patent abandoned.

2422 J. A. MCKEAN, Paris. Eyelet machinery. Dated narust 1, 1868.

2422 J. A. McKean, Paris. Eyelet machinery. Dated August 1, 1868.

This consists chiefly in the peculiar combination of dies, punches, and cutters, whereby the several operations, which each eyelet has to undergo, are performed simultaneously, in different sections of the machine, so that any desired number of eyelets may be finished in the same time that would be required to produce one single eyelet. Reciprocating punches are arranged in combination with rotating cylinders, perforated with series of holes to give the eyelets the required form, in the successive stages of their manufacture. The eyelets are produced from strips or sheets of brass or other metal, and each strip is first subjected to the action of one series of dies and punches, and is then passed under the next series, and so on, until brought to the required form, while, at the same time,

fresh strips introduced between the first set of dies and punches, follow the strip first introduced. Each strip, as it passes from the last series of dies, is brought into co with a cutting cylinder, which removes the ends o eyelets. The strips are annealed between the succe operations.—Patent completed, asses from the last series of dies, is brought into contact

2423 M. SAMUELSON, Hull. Hydraulic boxes, Dated August 1, 1868.

This relates to improvements in hydraulic press boxes, such as are in ordinary use in oil mills, and consists in the employment of wrought iron or steel in combination with cast iron, for the purpose of strengthening the same.—Patent abandoned.

2424 M. WILKINS and J. CLARK, Paddington. Boilers and

2424 M. WILKINS and J. CLARK, Paddington. Boilers and furnaces. Dated August 1, 1868.

The patentees form the boiler of a number of plates or sheets of metal, joined two-and-two round their edges, either by rivets or welding. Through these plates, holes are drilled about 8in. apart; ferrules or distance pieces are placed between them. The plates are arranged vertically side by side, with corresponding ferrules or distance pieces between each pair, they are bound together by binding bolts passing through the centre of the ferrules, and embracing the outside plates of the series. Water to supply the evaporation of the several cells is conducted along the centres of the ferrules, from a larger division or cell at each side of the boiler, and passes by holes in the ferrules to the several cells. In like manner, the steam is conducted to a steam chest or chamber, which may either be on the side or top of the boiler. The ferrules are made considerally larger than the diameter of the binding bolts, so that the water and steam may have free passage around the bolts, but where a passage for water or steam is not required, the ferrules are just so large as to allow the binding bolts to pass through their centres, and prevent the plates collapsing when the bolts are screwed tight.—Patent completed.

pleted.

2425 A. Arnold, Birmingham. Button fastener. Dated August 1, 1868.

This consists in forming the one part of the fastening, termed the back portion, with a socket or section of a tube secured to or upon a plate of suitable form. The second part or fastening piece consists of a shank secured to or upon a plate or stud, or to a portion of the article, and it is formed with a ball-shaped end, and is also split up from its bottom or ball shaped end towards the top or head, so as to act as a spring, and pass into the socket or tube upon the back plate, thus effecting the fastening of the two parts or ends of the article required to be secured. To free or disconnect the two parts, it is merely requisite to pull each end with a slight degree of force, which will cause the split shank to slide out of the socket or tube.—Patent abandoned.

2426 C. GEOGHEGAN, Dublin. Water regulators. Dated

Patent abandoned.

2426 C. Groghegan, Dublin. Water regulators. Dated Angust 1, 1868.

The object of this is to admit water or other fluids into elsterns or reservoirs in buildings at high pressure, and maintain it at all times at a fixed level, so that as soon as the water is drawn off by any outlet from the reservoir it refllis itself, the cock closing at the ordinary standing level in the cistern. Inside the cistern is fixed an inverted air vessel, with an open bottom fixed below the surface of the water at standing level, having an aperture at the top, connected with an air tube of small bore, carried down to the top of a closed vessel, having an aperture at the top and bottom only, the air pipe being attached securely to the upper aperture, and the bottom aperture being united to a vessel in a similar manner; this vessel has an open top in which water is allowed to stand at a fixed level until acted upon by the condensed air.—Patent completed.

2427 G. Wilson, Elgin. Ships' logs. Dated August 1,

2427 G. WILSON, Elgin. Ships' logs. Dated August 1,

This consists, in the first place, of a circular brass box, supported by and moving horizontally in a strong brass frame with turned-up ends, and of a cylinder with conical ends, one end having an universal joint attached, and the other a watertight screw plug. The motive power is on another cylinder of less length, and freely movable on the outside. This outer cylinder has cast upon it twelve vanes, which gives it the necessary motion in the sea, the vanes being obliquely placed. The outer cylinder is adjustable on the inner cylinder, to cause it to run deeper or less deep in the sea. A line of fine wire forms the connection between the motive power or cylinder and the ship, and gives motion to the machine on board.—Patent completed.

2428 J. SCOTT. Sheffield. Cattle food. Detect August 1

2428 J. Scorr, Sheffield. Cattle food. Dated August 1

1868.

The patentee takes grain of any kind suitable for any given class of animals, and grinds it; he then mixes bran, chopped hay, or straw or chaff, or other cheap ingredient; the mixture is then made into a paste with water, in which a little salt is dissolved. The paste is formed into cakes or loaves, and baked. Or the paste may be fermented with yeast or bran before being baked. The preparation or food is fit for use when broken or crushed. The proportions in which they are mixed vary according to the kind of animal to be fed.—Patent completed. pleted.

2429 H. O. ROBINSON, Glasgow. Dredging machine.

2429 H. O. ROBINSON, Glasgow. Dredging machine. Dated August 1, 1863.

The operation of dredging is performed by a spiral or helical cutter placed in a cylinder, both of them revolving together. A tube is connected to the cylinder through which the material so ascends up out of the water. The cylinder with the helical cutter is placed in a floating vessel in an inclined position, as in the common dredger, and driven by an engine. The action of the helice on the fluid material is to force it upwards through the tube, but in order to insure its ascent out of the water to any desired height, screw propellers are made to rotate within the tube, or the air in the tube is exhausted by any of the usual modes. The helical cutter or instrument thus constructed and placed is drawn or uryed against the bottom usual modes. The netical cutter or instrument thus constructed and placed is drawn or urged against the bottom by a ferward motion given to the vessel in the usual way. Patent completed.

2430 S. PLIMSOLL, Sheffield. Loading coals. Dated August 1, 1868.
This is chiefly applicable for transferring coals from railway trucks into barges. A shoot is provided sufficiently wide to receive the contents of two or more railway trucks to be unloaded at the same time. This is effected by bringing each truck over an aperture above the shoot, into which the coals are emptied from the

bottom of the truck. At the lower end of the inclined bottom of the truck. At the lower end of the inclined shoot are hinged flaps, which are provided with raised sides, and supported in a horizontal position by chains and pulleys, by the aid of which the hinged flaps may be inclined at any angle to the shoot desired. A wedge-shaped central division is placed near the lower end of the shoot to guide the coal on to the flaps. Two or more hinged doors or gratings are suspended in the inclined shoot (between the aperture through which the coals are received and the flaps), for the purpose of checking the coal in its descent.—Patent completed.

2431 J. R. Chonsky Canon-street. Looms. Dated

coal in its descent.—Patent completed.

2431 J. R. Caoskey, Cannon-street. Looms. Dated August 1, 1863.

This relates to shuttles driven by compressed air, by intervening between the shuttle box and the second wheel a flexible barrel or cylinder composed of rubber or canvas and discs of wood, from which air is forced on pressure being applied to one end, a valve opening at the other at the same time, the air rushes through the valve and shoots the shuttle through the shed of the warps.—Patent abandoned

doned.

[The granting of a patent to the applicant was refused by the Attorney General, on account of the particulars having been obtained by fraud.]

2432 L. C. BAILEY, War Office. Drawing pens, Dated August 1, 1868.

August 1, 1888.
The set screw is formed with a head, divided into radial spaces, with numbers thereon, after the manner of a scale. A cut on the upper blade close to the screw head forms a medial line with the centre of the pen, by which means the position of the screw and its divisions in relation to the fixed medial line will always serve to indicate the space between the points of the blades, so that the exact fineness or thickness of line can be drawn.

—Patent completed.

—Patent completed.

2433 G. M. SHORE, Dorset. Railway brakes. Dated August 1, 1868.

In order to increase the hold of the brake block upon the wheel, and also of the wheel upon the rail, and also to prolong the time during which a brake block will last, the patentee places in the face of the wooden brake block nails, screws, pins, bolts, or pieces of metal, by preference of chilled cast iron or steel. When the heads, ends, or tops of these nails are brought into contact with the tyre of the wheel, they give to it a slightly roughened surface, thereby increasing the hold of the brake block upon the wheel, and also of the wheel upon the rail or block.—Patent completed.

2434 G. T. BOUSFIELD, Brixton. Binding skirts. Dated

2434 G. T. BOUSFIELD, Brixton. Binding skirts. Dated August 1, 1868.

This relates to the binding of ladies' dresses, and consists of a binding material that presents an edge of indiatubber, or other flexible material impervious to water, below the edge of the skirt, to protect the same from wear by contact with the floor or ground.—Patent completed.

by contact with the floor or ground.—Patent completed. 2435 S. R. RENAUDIN, Strasbourg. Battery. Dated August 3, 1863.

The object of this invention is to protect troops from the fire of an enemy, and at the same time admit of their returning it whilst under shelter. It consists of a species of sheet iron presenting a concave surface or surfaces to the enemy, so that the shots striking them are repelled in the direction from whence they came. When consisting of more than one sheet of iron, they are made in two pieces precisely similar, and mounted on wheeled carriages having two wheels each, and are made to fold so as to having two wheels each, and are made to full each as a to facilitate their transport, and all alike when raised in position. They are to be supported by props or stays.—Patent abandoned.

position. They are to be supported by props or stays.—Patent abandoned.

2436 H. W. GARRETT and G. HOLCROFT, Manchester.

Firearms. Dated August 3, 1868.

This consists, first, in an improved mode of opening and closing the cartridge chamber. The patentees employ a sliding bolt, which has a longitudinal to-and-fro motion given to it by the operator in opening and closing the cartridge chamber. The sliding bolt is cylindrical, and its in the end of the barrel; a handle projects from the sliding bolt, the shank of which handle its in a recess in the barrel to lock the bolt when the cartridge chamber is closed, and a partially rotatory motion is also given to the sliding bolt to lock and unlock it. Second, in an improved mode of discharging the cartridge, consisting of the application of a triangular block or wedge placed between the end of the spindle of the nipple and the horizontal striker, which slides within the sliding bolt above referred to, and is provided with a spring to draw it back. By this means, when the hammer strikes the nipple, the triangular block or wedge transmits the motion to the horizon-al striker, and explodes the cartridge. Third, in an improved mode of applying a spring catch for drawing the cartridge case out, or partly out, of the barrel. This catch is acted upon by the sliding bolt, and when the bolt is drawn back to open the cartridge chamber, the catch comes against the edge of the cartridge case, and draws it back until it is at liberty to fall out of the cartridge chamber.—Patent abandoned.

2437 C. Wilson, Hull. Reging and furling sails. Dated August 3, 1868.

back until it is at liberty to fall out of the cartridge chamber.—Patent abandoned.

2437 C. Wilson, Hull. Reefing and furling sails. Dated August 3, 1868.

This consists in fitting to the inner end of the boom a forked socket having a hole for a pin to pass through. This pin is riveted or burred down inside the socket to allow the boom to revolve. The outer end of the pin is jointed to a second pin or bolt, which enters rings or collars fixed on the mast. A socket fits over the inner end of the boom, which socket forms part of a worm wheel. This wheel is geared into by a worm on a spindle having a crank handle or other appliance for turning it fitted thereto. On the outer end of the boom a collar is fitted which carries a loose ring so that the boom may turn freely. This collar has two or more other rings placed on it which act as friction rings, and other friction rings are fitted over the socket on the inner end of the boom. The worm wheel and worm may be enclosed in a casing so as to prevent any ropes fouling the same. To each of the hoops which travel up and down the mast a ring is fitted, having a portion removed or cut away so as to prevent any ropes fouling the same. To each of the hoops which travel up and down the mast a ring is fitted, having a portion removed or cut away so as to prevent any ropes fouling the same. To each of the sail to enter. The luff rope to which the sail is secured is passed into these rings, and is held therein by the cut away portion net being large enough for the rope to pass out of it.—Patent abandoned.

2438 T. Wardle Leeds. School desks. Dated August 3, 1868.

This relates to the upper part of the desk, which is used.

same with the form or board upon which the person using the desk sits. Instead of fixing such upper part of the desk rigidly at a fixed angle, the patentee fixes the same on hinges, so that the part of the desk which slopes when used as a writing desk can be made to assume a position forming a horizontal table, or the half of a table (if two desks be placed together) or to assume an upright position as a back to the seat, in which case the sitter will be seated in the contrary direction to that he would take when writing. The hinges employed are of a peculiar form, so that the centre of motion or the pivot on which the levers turn is placed at a distance of about 3in, from the face of the hinge, affixed to the board, and the two portions forming the hinge are cut in a circular pattern, so as to permit of two portions convenient for affixing stops to be in juxtaposition in each required position of the hinge. A pin is passed through one part of the hinge and engages in three holes in the other part of the hinge, so that when the pin is engaged in the first hole the board affixed to the hinge is in position nearly upright, so as to form a convenient back to a bench; when in the second hole, such board is at a convenient; shop for writing, and, from the form of the hinge, has travelled through such a space as not to overlap the seat more than is convenient; and in the third hole the board becomes flat and forms a narrow table, and two of such benches being placed together, at table of a useful breadth is formed.—Patent completed. same with the form or board upon which the person using

2432 W. Spence, Chancery-lane. Treating ores. Dated

2432 W. Spence, Chancery-lane. Treating ores. Dated August 4, 1868.

The ores are first ground and intimately mixed with a suitable proportion of iron pyrites. This mixture is heated by superheated steam in a rotary cylinder. The heated or roasted ores are then amaigamated by a simple process of trituration, with a suitable proportion of mercury, but without the addition of any reagents. The triturating apparatus consists of a circular trough, within which four grinding stones revolve. Rakes and scrapers are arranged so as to act between them. The next part of the process is the separation of the amalgams. This is followed by the compression of the mercury for separating a great part of the free mercury. The remaining operations, consist of the distillation of the mercury, the precious metals, and the treatment of the residuums, which are conducted as usual.—Patent completed.

2440 H. A. BONNEVILLE, Paris. Preceiving meat. Dated

2440 H. A. BONNEVILLE, Paris. Preserving meat. Dated August 4, 1868.

August 4, 1868.

The meat is first deprived of its marrow bones, and then wiped and pressed in linen, so as to do away with the blood and moisture, and then, in order to cosqulate the albuminous substances, it is heated in an apparatus provided with a double perforated bottom, on which the bits of meat are placed, and underneath which water is made to boil. Sometimes the patentee preserves the meat without applying heat; in this case, it is besprinkled with powdered saltpetre by means of a sieve, in the proportions of about 1-300th of the weight of the meat, after which it is covered over with a layer of olive oil by means of a brush, and then placed in bags and pressed, to render it firm and compact in the animal charcoal. It is arranged in layers of animal charcoal, broken to the size of peas. This charcoal absorbs the air and the gases exhaled by the meat. The apparatus for the meat is internally divided by perforated sheet iron diaphragms resting upon annular ribs, placed at a distance of about 6jin, from one another.—Platent completed.

2441 H. A. BONNEVILLE, Paris. Dyeing fabrics. Dated The meat is first deprived of its marrow bones, and then

6 jin. from one another.—Patent completed.

2441 H. A. Bonneville, Parls. Dyeing fabrics. Dated August 4, 1863.

This relates to the use of pumps in lien of hand labour, in order to perform the various operations preliminary to the dyeing, the dyeing process itself, and the drying of the textile materials. To that effect, one or several troughs are used containing the liquids employed in these different operations, and a special trough is used, in which is suspended the textile material to be treated. This trough is furnished with a false perforated bottom and its hollow lid, the bottom of which is also perforated. This hollow lid and the trough, below its false bottom, are put into communication by means of pipes with the other troughs, and numeration by means of the switch the other troughs, and according to the nature of the operation to be effected, the liquid of one of the troughs is sucked by a pump and forced into the hollow lid, whence it flows upon the materials.—Patent abandoned.

2442 A. L. HOFFMANN, Poplar. Ships' yards. Dated August 4, 1868.

The yard is formed of metal, and hollow, to contain the roller, to which the upper edge of the sail is made fast. The sail passes from this roller through a longitudinal slit or opening provided for it along one surface of the yard. Theyard maybe strengthened by quarter battens, and otherwise, and there also may be quarter strengtheners to aid in the support of the roller sqainst bending, if desired. Reeding chains or cords are wound around the ends of the roller, in order that when they are drawn upon to cause the rotation chains or cords are wound around the ends of the roller, in order that when they are drawn upon to cause the rotation of the roller the sail may be wound thereon. The surface of the sail may be increased when the sail is made fast to another yard, or otherwise, at its lower end, by simply raising the yard, by halyards, or otherwise, until the desired amount of sail has been given out. The sail may be tightened up by drawing on the reeting cords.—Patent abandoned.

2443 R. SCHOMBURG, London-street. Brick machinery.

2443 R. SCHOMBURG, London-street. Brick machinery, Dated August 4, 1868.

This consists of a pug mill of the ordinary construction mounted above a series of moulds, which are placed in a circular or rectangular framing. The clay or other material is forced down to the lower part of the pug mill, where it enters moulds carried upon a circular table, which has a rotary motion communicated to it in any suitable manner. Beneath the table a wheel or drum is placed, upon which the bottom of the moulds are brought to bear in their rotation. This wheel causes the moulds to rise so as to bring the upper surface against the under side of a fixed table or plank; in this operation the clay becomes compressed within the mould; the moulds with the material within them then pass on towards a second wheel or drum, by which the bottom of the mould is lifted, so as to cause the moulded articles to project beyond the top of its mould, it can then be removed to a drying stack, or if the clay is sufficiently free from moisture, it can be stacked or otherwise treated for burning.—Patent abandoned.

2444 B. J. B. Mills, Chancery-lane. Harcesting machines.

the cut away portion n-t being large enough for the rope to pass out of it.—Patent abundoned.

2438 T. Ward, Leeds. School decks. Dated August 3, 1868
This relates to the upper part of the desk, which is used or writing or supporting a book, and which is usually attached to an upright piece of wood, connecting the

towards the cutters, whilst one or more of them are, in addition to gathering the standing crop towards the cutters, caused to sweep the cut crop off the platform, the others being caused to travel above the platform clear of the cut crop thereon, cams being used to impart the various motions to the rakes or beaters, and this part of the invention consists in making a portion of the cam way opposite to the platform which guides the rakes or beaters which gather, but do not discharge the crop, movable, so as to cause the arms of any one of these heads or beaters to descend on to the platform and become a discharging rake by following the auxiliary cam for the time being the movable cam way at the will of the driver, instead of the driver directly operating the movable cam way. This arrangement prevents the roller at the heel of the rake arms from ever coming in contact with the point of the movable cam way, and prevents the possibility of two revolving arms next to each other in succession from following that cam way by which they would be made to discharge the cut crop from the platform.—Patent completed.

2445 C. F. C. CRETIN, Glasgow. Lamps. Dated August 4, 1863.

The interior of a gas lamp is provided with a burner which communicates by a pipe leading to a gas holder or reservoir from which the gas is supplied. The air necessary for maintaining the combustion of the gas enters the sary for maintaining the combustion of the gas enters the airtight gas tube by several holes or perforations situated around and below the burner. The carbonic and other products of combustion are drawn off by means of a fan or ventilator, so that the products of combustion are discharged at the outer extremities of the vancs. In this way, a partial vacuum is effected, and, consequently, fresh air descends the air pipe, and is supplied continuously to maintain the combustion of gas.—Patent abandoned.

2145 F. F. MANN. Publish. Figure 2019. Detail August 4.

2446 E. EVANS, Denbigh. Flour mills. Dated August 4,

2446 E. Evans, Denbigh. Flour mills. Dated August 4, 1868.

Three millstones are employed, set vertically. The middle stone is capable of rotation, while the other two are fixed. The rotating stone is provided with two grinding surfaces which are dressed as usual. Each of the grinding surfaces of the fixed stones has half its furrows draughted at different angles from the other half, for the purpose of accelerating the discharge on the ascending half and retarding it on the descending half. The rotating stone is driven by means of a pulley on its periphery, around which a band passes, the band taking motion from any prime mover. The outer or fixed stones are hung or mounted in universal joints or gimbals, the bearings of which are made capable of sliding longitudinally on the frame. Weights are suspended from the lower sides of the stones for balancing their grinding surfaces in a vertical position. The rotating stone is adjusted between the outer ones, and is mounted upon a horizontal shaft which passes through the eyes of the fixed outer stones, the said shaft turning in bearings. On the shaft of the rotating stone, and situated part within and beyond the eyes of the outer stones, are two worms, which worms work in casings which receive the grain from the hoppers. By the rotation of the shaft, the worms convey the grain through the casings in the eyes of the outer stones to the grinding surfaces.—Patent completed.

2447 J. FRAZER and W. NAAR, Bayswater. Mattresses. Dated August 4, 1868.

Dated August 4, 1868.

The upper surface of spring mattresses is so made as to set the head of the mattress higher than the foot. To this end, the mattress is made with a base and an upper frame connected together by springs. To the ends of the frames fastenings are employed for drawing the frames together, so that the foot of the mattress may be depressed and the head elevated at pleasure.—Patent abandoned.

2448 A. V. Newton, Chancery-lane. Boot swing machinery. Dated August 4, 1868.

This consists in making the table adjustable to suit various sized lasts, and in fitting the whole of the sewing apparatus above the table, and actuating the same by means of a treadle. A peculiar arrangement of mechanism is employed for working the needle, and a lamp for heating the thread on its way to the needle.—Patent completed.

pleted.

2449 F. W. Kitson and P. Chalas, Leeds. Priction clutches. Dated August 4, 1868.

This consists in forming one of the discs hollow, and fitting plungers or pistons through the face plate; the pistons are connected with a plate on the outside of the disc; on pressure being applied, the pistons are forced outwards, and the plate bears against the moving disc with sufficient force to compel it to follow its course. The water from the hydraulic pump, when water is used, is supplied to the main shaft, which is perforated for that purpose.—Patent completed.

purpose.—Patent completed.

2450 C. G. JOHNSON, Stockton-on-Tees. Brick machinery. Dated August 4, 1868.

A pug mill is employed in combination with boxes or moulds, set in a circular or rectangular table, revolving or milding reciprocatingly beneath an aperture in the pug mill, in such manner that the boxes or moulds are, by the movement of the table, brought in succession opposite the oritice of the pug mill, and are from it filled with clay, concrete, coal dust, or other substance, to be moulded into a block. When the moulds have been moved past the orifice of the pug mill the materials in the moulds are subjected to pressure, by a piston which forms the bottom of the mould being forced upwards by its lower end coming against an incline or cam surface, whilst the top of the mould is at this time covered over with a lid or plate. The bricks or blocks are subsequently discharged from the moulds by cams or levers, and are removed; it may be either by hand, or by appliances to push them off the table on to a creeper.—Patent completed.

2451 J. Hamilton, Holland. Artificial fuel. Dated

2451 J. HAMILTON, Holland. Artificial fuel. Dated August 5, 1868.

Atolerate Jan. Dated August 5, 1868.

The patentee takes about 20cwt. of "Duff" coal or other carbonaceous material in a pulverized state, and from lewt. to 4cwt. of stearine, pltch, palm oil, or other animal or vegetable residuums; these are mixed with from lewt to 3cwt of chloride of spolium, in the form of rock or other salt. The mixture of these ingredients is effected in a pug mill. In order to facilitate cohesion between the ingredients so combined, the waste substances resulting from the manufacture of farina or the silicates of soda or potash may be added thereto. The resulting compounds can then be formed into bricks or balls for use, as may be desired,—Patent abandoned.

2452 T. B. OSWALD, Sunderland. War ships. Dated August 5, 1868.

The patentee proposes to build a low vessel with only some 44ft. freeboard when all complete, which is to be made quite shot proof. On the deck of this vessel for half its length amidships and three-quarters its beam on deck an oblong battery is erected; the remaining space on deck is also bomb proof, whose sides and ends lay at an angle of 45deg, or thereabouts, more or less, and whose top is circular. This battery stands some 9ft above the deck, and is plerced at the two sides and ends for the largest size of guns. This battery is enclosed in a light but watertight spar deck, wherein the officers and crew have their accommodation.—Patent abandoned.

have their accommodation.—Patent abandoned.

2453 A. V. Newton, Chancery-lane. Iron and steel.
Dated August 5, 1868.

The first part consists in the use of a flux composed of manganese and common salt (chloride of sodium) in a moist or wet state, with limestone or shells, such flux being introduced into the furnace during and after the fusion of the metal, in order to decarbonize it and to cause the expulsion and carrying off of silicon, sulphur, phosphorus, and other impurities, and bring the iron to such a state that on its being simply cast into moulds it will have the character of cast steel without further manipulation, and may, when cast in ingot moulds, be subjected to the operations of hammering and rolling to reduce it to the form of bars of any required shape for the manufacture of tools or other articles requiring hardness and temper.—Patent completed.

2454 N. D. Spartall, Liverpool. Propelling vessels.

2454 N. D. SPARTALI, Liverpool. Propelling vessels.
Dated August 5, 1868.
Blasts of wind are produced from a blower, constructed on the turbine principle, discharging such wind into the water from the stern, or the sides of the vessel. This blower may be worked by a donkey or other engine, and the blast therefrom discharged into a serpentine pipe or pipes, which may terminate in a trumpet mouth for spreading the blast.—Patent abandoned.

2455 W. MILLARD, Trowbridge. Looms. Dated August 6,

1868.

The improvements are especially applicable to power looms for weaving check patterns, and have for their object the causing the shuttle boxes to stand more firmly to their work, and avoid tendency to kick; they comprise sinking, square, or rectangular, and circular, or partly circular grooves, in the back of the frame, holding the shuttle boxes, and providing guides of corresponding shape (or nearly so) working in such grooves. Also making the grooves and slides, or either of them, with the grooves sunk in the slay sword or vibrating upright, which carries the slay beam at one end, and into a cap securing slide at the other.—Patent completed.

2456 H. CHURCHMAN, Horsham. Boot cleaner. Dated August 6, 1868.

August 6, 1868.

This consists in constructing rotary brushes in the following manner:—A circular concave brush, the surface of which is formed round or concave at bottom, widening out to a certain point from which the brush surface again contracts towards the rim of the brush, it being made to extend partially or completely over such rim. By this form of brush, the boot is effectually acted upon in all parts, as the sole being made to fit into the widest point of the side surfaces, the front of the upper leather is cleaned by the concave bottom brush surface, while the sides of the boot are acted upon by the contracted side brush surfaces.—Putent completed.

2457 E. Enwards Wastminster. Pumns. Dated August 6.

2457 E. EDWARDS, Westminster. Pumps. Dated August 6,

2457 E. EDWARDS, Westminster. Pumps. Dated August 6, 1863.
This consists in making pumps with flexible rings instead of pistons or plungers, and flexible discs or plates for valves. For ordinary lift pumps, the patentee forms a tube, the upper part of which is expanded into a cup shape, and has a flange at the top. Upon this tube another cup having a corresponding flange is fastened. In the upper part of the lower tube, and in a recess just below the cup, a horizontal plate perforated with holes is placed, which forms the seat of a flexible valve; a bar is fitted having a per foration through it of sufficient length and depth to allow a disc of flexible material to be passed through it, which disc, being held down by the bar, but allowed to bend up on each side of it, forms a watertight valve opening upwards.—Patent completed.

2458 M. BENSON, Manchester-square. Indicators and

on each side of it, forms a wateright valve opening upwards.—Patent completed.

2458 M. Benson, Mauchester-square. Indicators and valves. Dated August 6, 1868.

This relates to an attachment to steam boilers, to serve as a safety valve, and give warning of a deficiency of water in the boiler, the valve is made large enough to provide it with an elbow chamber, for attaching tubing; one of the tubes is attached to the chamber, at the underpart of the valve, and its end extends down through the valve pipe or dome into the boiler, and a little below the proper level of the water. Another tube is horizontally attached to the side of the valve in the chamber, and on the outside of the boiler which communicates with the one before described. The horizontal tubes serve as a lever, and is bent up at its outer end, to which a globe or vessel for containing water is attached; the water in the globe serves as a weight for holding down the valve. The top of the globe is provided with a cock to let out the air when the water is forced into it from the boiler, which is done by the steam.—Patent completed.

2459 L. PRICE, Birmingham. Candistick slides. Dated

2459 L. PRICE, Birmingham. Candlestick slides. Dated

August 6, 1868.

This consists in making spring slides for candlesticks. A strip of iron is employed of greater length than that ordinarily employed, and the free side of the spring slide is made of greater length than usual. The lower part of the free side is carved into a nearly semicircular figure, the concave side of the curve being turned towards the other side of the spring slide. The bottom of the free side of the slide being bent inwards constitutes a stop which prevents the too great compression of the parts.—Patent abandoned. abandoned.

2460 W. PEARSON, and W. SPURR and H. BRADBURY,

2400 W. Pearson, and W. Spurr and H. Bradburt,
Birstall. Looms. Dated August 6, 1868.

This relates to self-acting means of working the rising boxes or change shuttle boxes employed in booms for wearing fabrics, for which jacquard or other indicating apparatus is used to select the different colours or kinds of weft required, and consists in the construction of apparatus whereby the indicating or governing apparatus may be readily "lagged back," reversed, or altered at any time without altering or otherwise moving any of the other parts of the loom. In one arrangement for this pur-

pose, the patentees employ the well-known "star wheel" intermittent motion. To the star wheel a barrel is fixed, on the surface of which are arranged a series of slidable tappets, equal in number to the number of points, places, or notches in the star wheel. These tappets are formed in steps or different lifts, two, three, or more, according to the number of change boxes used, and are arranged under the box levers, so that as the star wheel rotates (intermittently) the tappets may be placed in suitable position for contact with the friction roller of the lever, and thereby cause it to operate the boxes. The jacquard apparatus or peg lags or other indicating apparatus are arranged to operate upon these tappets by means of levers and rods, so as to slide the tappets into proper position, as required for contact with the box levers.—Patent completed.

2461 J Hargraves Durham. Iron and steel. Dated

as required for contact with the box levers.—Patent completed.

2461 J. HARGRAVES, Durham. Iros and ites. Dated August 6, 1863.

The patentee states that during the manufacturing of steel or malleable iron, by any of the processes, in which the carbon, silicon, and other impurities are removed by the action of currents of oxygen, ascending through fused cast iron, such, for instance, as the Bessemer, or where the conversion is effected by passing oxygen, by the action of heat and carbonaceous matter, such, for example, as the nitrates, chlorates, and manganates. Into the converting vessel or other apparatus, in which the cast iron is being operated upon by ascending currents of oxygen gas, or atmospheric air, or other compound, capable of evolving oxygen is projected, whether the said-compound of oxygen be in a gaseous, liquid, or solid condition. Instead of oxygen may consist of nitrate of soda, or nitrate of potassa, or chlorate of soda, or chlorate of potassa, or other salt, which yields oxygen, injected upon the surface of the iron, which is being operated upon as aforesaid, by ascending currents of oxygen. The patentee injects the oxygen gas or atmospheric air, or oxygen yielding salt or other compound, capable of evolving oxygen above the surface of the iron, and slag being operated upon by the ascending currents of oxygen or compound thereof, as aforesaid, downwards upon the surface of the iron, and slag being operated upon by the ascending currents of oxygen or compound thereof, as aforesaid, downwards upon the surface of the metal and slag, and it is further preferred that the gas or airor oxygen vielding salt, should be heated previous to being injected. The temperature of the converter is elevated by the combustion of the evolved carbonic oxide within the converter.—Patent completed.

2462 H. F. Freistel and H. Zox, Blackfriars-road.

-Patent completed.

2463 H. F. FREISTEL and H. ZOX, Blackfriars-road.

Hats and caps. Dated August 6, 1868.

The patentees propose to maunfacture the hat, cap. or other covering of a woven material, consisting of horse hair, or of hair mixed with cotton or other fibrous material, which may be of any colour or series of colours desired, or which may consist of a printed warp. The fabric thus woven is to be applied in a double layer to form the body of the article required. The fabrics when placed side by side are reversed in the direction of their warps and wefts, those of one fabric being placed in a position at or near a right angle to those of the other. It may be treated with any outer material or fabric, such as silk or other fabric, to form the exterior, in which case the effect of a blow or pressure upon the article will not be permanent, but will disappear by the spring of the compound hair fabric.—Patent abandoned.

#### [APPLICATIONS FOR LETTERS PATENT.

Dated February 15, 1869.

460 A. H. Lewis, Fenwicke-street, Liverpool. Improvements in extracting copper from its ores.

461 T. Hattersley, Leeds. Improvements in spindles and figers used in the spinning and preparing of flux, tow, hemp, jute, worsted, wool, cotton, silk, and other fibrous substances.

462 C. W. Lancaster, New Bond-street, Middlesex. A hollow wadding for breech-loading cartridges.

Dated February 18, 1869.

463 S. Shaw, Southampton-buildings, Chancery-lane. Improvements in devices for lacing and buttoning boots and shoes.

nd shoes. 464 T. Bond, Liverpool. Improvements in machinery be employed in the construction of casks. 465 T. Winder, Liverpool. An improved spring coupl-

10g.
466 H. Posen, Christopher-street, Finsbury. An improved fastening for purses, pocket books, belts, and

other articles.

467 T. Billyeald, Nottingham. Improvements in the manufacture of nets for ladies' hair.

468 W. Smartt, Buckhurst Hill, Essex. Using the heat which is usually under sitting room, office, and other similar fires, and which is thrown off from the said fires and from the hot ashes which fall from them, for cooking, warming and drein purposes.

and from the hot ashes which fall from them, for cooking, warming, and drying purposes.

469 L. N. Legras, Wardour-street. Improvements in the preservation and disinfection of animal and other substances, and in the apparatus employed therein.

470 V. A. Houdaille, Boulevard Sebastopol, Paris, Improvements in metallic burgs for pressure vessels or vas specially applicable to brewers.

471 G. W. R. Pigott, Halifax. Improvements in machinery or apparatus for the consecutive manufacture of various articles of commerce from materials capable of being formed either by tension, compression, or extension thereof.

B. J. B. Mills. Southampton-buildings, Middlesex.

472 B. J. B. Mills, Southampton-buildings, Mtddlesex. Improvements in brick-making machinery.
473 C. E. Brooman, Fleet-street, City, patent agent. Improvements in treating the waste of wool, silk, horn, and other nitrogenized animal matters to be used as manure. (A communication).
474 H. Tylor, Queen-street, City. Spring bedsteads.
475 A. M.Neile and J. Slater, John-street, Pentonville. Improvements in carriage wheels.
476 J. Fletcher, Bow. Improvements in feeding begass furnaces, and in begass furnaces, and in apparatus applied thereto.

479 J. W. Yates, Birmingham. An improvement of improvements in spades, shovels, forks, and other similar articles.

articles.

Dated February 17, 1869.

480 T. Sagar and T. Richmond, Burnley. Certain improvements in looms for weaving.

481 J. B. and B. Wood, Sowerby Bridge, Yorkshire. Improvements in, or applicable to, steam engines.

482 E. T. Hughes, Chancery-lane. Improvements in washing machines.

483 J. Atkins, Birmingham. Improvements in the manufacture of metallic bedsteads and other articles of metallic furniture.

484 E. Bound, Sheffield. Improvements in vessels for holding and cooling or warming fluids or solids.

manufacture of metallic bedsteads and other articles of metallic furniture.

484 E. Round, Sheffield. Improvements in vessels for holding and cooling or warming fluids or solids.

485 W. E. Newton, Chancery-lane. Improvements in adhesive stamps applicable for postal, internal revenue, and other purposes or uses, a portion of which improvements in the construction of the permanent way of railways.

486 F. H. Collins, Kensington Gardens. Improvements in the construction of the permanent way of railways.

487 A. Ransome, King's-road, Chelsea. Improvements in wood-cutting machinery.

488 W. R. Lake, Southampton-buildings, Chancery-lane. An improved method of obtaining benzole and its homologous substances from coal gas.

489 H. D. Bowyer, Ripley, Woking, and J. L. Norton, Belle Sauvage-yard, City, Improvements in the manufacture of wheaten flour.

Dated February 18, 1869.

490 H. Aland, Richard-street, Roupell-street, Surrey, Improvements in compound rotary blowing fans for producing a compound blast of high density.

491 F. J. Knewstub, St. James-street, Westminster, Improvements in fittings to be employed in despatch, writing, and other cases, boxes, drawers, or receptacles, which fittings can also be made to be used separately.

492 J. Darlington, Moorgato-street Chambers, City, Improvements in mineral and rock-drilling apparatus.

493 A. Rartholomew, Queen's-place, Great Westernroad, Glasgow. Improvements in apparatus for regulating the opening of sliding windows.

494 A. Muuro, Arbreath, and W. B. Adamson, Glasgow. Improvements in tools and machinery employed for cutting stone, slate, marble, rock, and other substances.

495 A. Garrison, Birmingham. An improved pendant string bolder.

496 J. D. Nichol and J. Eckersley, Edinburgh, Improvements in apparatus for drying and pressing printed paper.

paper.
497 C. Brook and M. Thompson, Halifax, and L. Barker,
Balldon, Yorkshire. Improvements in looms for weaving.
498 R. Pyne, Wellington-street, Strand. Improvements
in the construction of steps for the doors of railway and

other carriages.

499 J. A. Wade and J. Cherry, Hornsea, Yorkshire,
An improved machine for pressing bricks, tiles, or other

articles.
500 T. H. Martin, Swansea. An improved method for tightening piston rings to the cylinders of steam or other

engines.
501 D. G. FitzGerald, Battersea. A new or improved mode of constructing electric telegraphs and voltaic

mode of combinations batteries.

502 J. Newton, Leeds. Improvements in machinery for spinning flax and other fibres.

503 W. Daines, Gravesend. Improvements in anchors.

504 F. W. Mallett, New Haven, Connecticut, U.S.A. An improved machine for making sewing needles.

505 M. Vary, Scarborough. Improvements in ornamenting surfaces.

505 M. Vary, Scarborough. Improvements in ornamenting surfaces.
506 F. Delbreil, Versailles, France. Improvements in apparatus for the removing and facilitating the utilization of excrementitious or other refuse matter which passes into sewers, or is deposited in cesspools, or elsewhere, in cities, towns, and other localities.
507 T. Forster and P. B. Cow, jun., Streatham, Surrey. Improvements in the manufacture of india-rubber suction and other pipes, and of hose, buckets, bags, and such like vessels, for conveying or holding water or other liquids.

Dated February 19, 1869.

and other pipes, and or nose, outcasts, or other liquids.

Vessels, for conveying or holding water or other liquids.

Dated February 19, 1869.

508 W. M. Cochrane, Surbiton. Improvements in vessels for containing water and other liquids, and in means for suspending and carrying the same.

509 T. Tunstill and J. Dodgeon, Burnley. Improvements in looms for weaving.

510 E. Dorsett, London-street, City. Improvements in means and apparatus for heating, smelting, and working metals, and in furnaces employed therein, which improvements and apparatus for heating and otherwise operating upon minerals and other substances.

511 A. Henry, Edinburgh. Improvements in breechloading firearms.

512 L. G. Moore, Erith. Improvements in the construction of feathering sails for windmills.

513 J. Loader, Finsbury. Improvements in steam generators.

tion of feathering sails for windmills.

513 J. Loader, Finsbury. Improvements in steam generators.

514 S. Myers, New Bond-street. Improvements in churns, also in apparatus for whipping or beating eggs and performing other similar operations.

515 T. Smith, Manchester. Improvements in the treatment of fiannel, carpets, druggets, trouserings, broad and other woollen cloths.

516 J. Davey. Wisboach, Cambridge. Improvements in the construction of motive-power engines.

517 A. M. Clark, Chancery-lane. Improved means for increasing the tractive power of road and other locomotive engines and carriages.

518 E. Hewett, St. Leonard's-on-Sea. Improvements in cowls for chimneys and shafts.

519 H. T. and T. Jennings, Sidney-street, City-road. Improvements in steam engines.

520 J. Barton, Church-street, Birkenhead. An improved water heater.

521 W. R. Lake, Southampton-buildings, Chancerylane. An improved mode of, and means for, making and preserving ice, for cooling liquids, and for preserving the same and other substances.

522 M. M'Lennan, Liverpool. An improved permanent way.

Dated February 20, 1869.

way.

Dated February 20, 1869.

523 G. G. Hairs, Little Distaff-lane, City. Improvements in burning and vaporizing combustible liquids to obtain light and heat, and in apparatus employed therein.

524 G. Green, Aberystwith. Improvements in buddles for separating ores and other materials.

525 J. D. Gauldie and T. A. Marshall, Glasgow. Improvements in steam engines and boilers.

526 J. T. Wibberley, Leicester. Improvements in machinery or apparatus for winding cotton, silk, wool, or other threads, on spools or reols.

527 J. Mabson, Norwood. Improvements in appliances

627 J. Mabson, Norwood. Improvements in appliances for drawing corks, and for receiving the wax and dirt which fall therefrom. 528

A. Jacob, Bromley. Improvements in the ventila-

tion of sewers, 529 J. Eberhard, Tolmer-square, Hampstead-road. Im-provements in apparatus for propelling ships and other

530 H. W. Whitehead, Holbeck. Improvements in machinery for combing wool, cotton, flax, and other fibrous

machinery for combing woot, cotton, mas, substances.

531 M. Gray, Highbury Hill. An improvement in the manufacture of covered electrical conductors.

532 J. H. Morl, Cambridge. Improvements in har-cutting machines, also applicable to clipping or shearing sheep and other animals.

533 T. H. Simmonda, Great Mitchell-street, St. Luke's, and E. B. Moreland, Bartholomew-close, City. An improved compound for glazing or finishing linen-faced paper used in the manufacture of collars and cuffs, and for other purposes.

paper used in the manufacture of collars and cuffs, and for other purposes.

534 B. F. West, Southampton-buildings, Chancery-lane. An improved double-jointed butt-hinge.

535 F. G. Fleury, Merrick-square, Southwark. Improvements in meters or apparatus for measuring water and other liquids.

536 J. Daglish, Dene House, Seaham Harbour, Durham. Improvements in the ventilation of mines.

537 R. Forster, Buxton. Improvements in the construction of boilers.

538 J. E. Lucas, Allhallows Chambers, Lombard street.

Lucas, Allhallows Chambers, Lombard-street

538 J. E. Lucas, Allhallows Chambers, Lombard-street, City. An improved floating velocipede.

Date February 22, 1869.
539 J. and W. Weems, Johnstone, Renfrewshire. Improvements in machinery, apparatus, or means for malting, heating, drying, cooling, and ventilating, 540 W. Ibotson, New Inn, Strand, W. W. Ladelle, Wrayshury, Bucks, and A. G. Southby, Bulford House, near Amesbury, Wilts. An improved method of, and apparatus for, preparing esparto, straw, rags, or other materials for the manufacture of paper.
541 S. Osborn, Sheffield. Improvements in knives and knife bars for reaping and mowing machines.
542 J. O. C. Phillips, Birmingham. An improvement or improvements in the construction of sets or partial sets of artificial teeth.

improvements in the construction of sets or partial sets of artificial teeth.

543 J. W. Reid, Great Western-terrace, Bayswater. An improved mode of, and means for, preducing paper pulp or half stuff from wood and other fibrous materials.

544 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in heating apparatus for locomotive enzines.

engines.
545 G. A. Fall, Hoboken, New Jersey, U.S.A. Improvements in propelling vessels.
646 T. S. Blair, Tavistock Hotel, Covent-garden, Improvements in the manufacture of iron and steel.
547 J. and T. Leach and J. Goodyear, Rochdale, Improvements in machinery or apparatus for winding slivers or laps of wool, flax, cotton, or other fibrous materials.
548 B. J. B. Mills, Southampton-buildings, Middlesex, Improvements in the manufacture of artificial stone.
549 J. E. Liller, Bedford. Improvements in apparatus for printing.

for printing.

550 J. H. Johnson, Lincoln's Inn-fields. Improvements

in velocipedes.
551 W. E. Newton, Chancery-lane. Improvements in acrew wrenches. screw wrenches. 52 J. B. Rushbrook, St. Andrew's street, North, Bury Edmunds. An improved hurdle for folds for lambs

and sheep.

553 R. Meldrum, Pittormie, Cupar. Improvements in machinery or appuratus for stopping locomotive and other engines and vehicles or machinery when connected therewith.

554 J. Blyde, Sheffield. Improvements in scissors, or apparatus especially suitable for gathering flowers.

555 H. F. Freutel, Kingsland-road, Middlesex. Improvements in the manufacture of hats and caps, and other coverings for the head.

556 R. P. Williams, Great George-street, Westminster. Improvements in railway crossings and switches.

# NOTICES OF INTENTION TO PROCEED WITH PATENTS. From the "London Gazette," February 23, 1869.

### LIST OF SEALED PATENTS. Sealed February 19, 1869.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co. Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

## THOMAS TURTON AND SONS,

CAST STEEL for Cuttors, Punches, Taps, and s, Turning Tools, Chisels, &c

CAST STEEL Piston Rods, Crank Pins, Connecting Rods, Straight and Crank Axles, Shafts, and Forgings of

FILES, marked T. TURTON. Superior to any other make. (See results of trial in the "Times." July 26, 1851.)

TOOLS of all kinds for Engineers, Railways, Con-

EDGE TOOLS, marked WM. GREAVES and SONS. Electro-Boracic Steel, warranted to wear out three Tools made of Cast Steel.

DOUBLE SHEAR STEEL, SPRING STEEL, BLISTER STEEL, GERMAN STEEL.
SPRINGS, BUFFERS, and CAST STEEL TYRES
For Locomotive Engines, Railway Carriages, and Waggons.

SHEAF WORKS and SPRING WORKS,
SHEFFIELD.
London Warehouse: 35. QUEEN-STREET, CITY,
Where the Larger Stock of Steel, Piles, Tools, &c., &c., may be selected from.

#### EXPLOSIVE COMPOUNDS FOR PROJECTILE PURPOSES.

UNPOWDER, which has been in use for so many years, may now be considered as perfect as it can be made, as regards projectile force and uniformity of combustion. Recent attempts have been made to employ it in a more condensed form, by compressing the charges, but these have failed to a great extent. Of late years, several new explosive compounds have been manufactured as substitutes for gunpowder, and they have, for the most part, been described in our columns. It is claimed for them, generally, that they possess greater cleanliness, almost total absence of smoke, less sensible recoil for a given velocity of projectile, and reduction of danger in manufacture, as being less violently explosive in an unconfined state. These may be considered as the general claims to superiority of the new explosives. Being principally composed of vegetable fibres nitrogenized, they might aptly be termed explosive fibres. Those now in use are known as gun-cotton, wood-powder, and gun-felt. As a few years' experience only in the production of these compounds can be placed against as many centuries in the production of gunpowder, it is reasonable to expect further progress and improvement in these new substances. When gun-cotton was first discovered, its obvious advantages induced several governments to adopt it in the place of gunpowder. The nature of this substance, however, not being thoroughly understood, many serious accidents resulted from its use. The too rapid combustion injured arms in which it was employed, and it was further found to lack uniformity in firing; in fact, for the most part, gun-cotton was abandoned in disgust. Recently, however, many ingenious methods have been adopted to retard in discust. this great rapidity of combustion, and although gun-cotton can be and is used in shot guns with comparative safety, still it has not yet been produced with sufficient uniformity or slowness of combustion to shoot accurately in rifles. Until this be done, it cannot be considered as a perfect substitute for ordinary gunpowder. Gun-cotton, however, can now be produced in such a condition that it may be stored with safety and without fear of deterioration; and thus prepared, it is largely used for mining and engineering purposes.

Schultze's wood-powder is composed of minute cubes of hard wood, treated in a manner analogous to gun-cotton, and subsequently impregnated with other substances; it is used in a pure state, and requires compressing with considerable force, in order to obtain the best results. It can be fired in rifles, and this is a proof of a certain amount of uniformity, though it occupies a greater volume than gunpowder to give an equal initial velocity to the bullet. Reeves's gunfelt-another comparatively recent invention is composed of vegetable fibres, which are also treated analogously to gun-cotton, and subsequently impregnated with other mate-This compound is also used in a pure state, and can be fired in rifles. This material was invented and is now being manufactured by Messrs. Reeves and Co., of Glastonbury. It has been found to answer exceedingly well, both in sporting guns and in rifles, but, pending some practical trials which are to be made with this material in a

These two last-mentioned comformances. pounds are made of several different strengths. and the weight of charges used relatively to gunpowder is, of wood-powder, about onehalf, and gun-felt one-third, i.e., one is three times and the other double as strong as ordinary powder. These new explosives ignite at a much lower temperature than powder, but being composed of less solid matter, the combustion generates less heat, and as many rounds can be fired in a gun or rifle with as much safety as with gunpowder. The fouling is also considerably lessened; the ignition, although quick, does not impart the same sensible recoil. The more solid forms of fibre, such as wood-powder, give more recoil than gun-felt, from which it may be inferred that the elasticity of a compound to a certain extent checks in itself the sudden shock of ignition.

The reduction of recoil in military weapons is of some importance, as it limits the weight and velocity of the bullet. Action and reaction on the bullet and breech of gun may be the same, but when the gases are generated in a gradual manner, the sensible recoil must necessarily be reduced. Even with gunpowder this can be proved by experiment, as quick burning powder will give much greater recoil, with the same initial velocity imparted to the bullet, than a slow burning one. No doubt, the great portion of the motive power exerted by explosives is instantaneous in its action, and ought not to be generated before it is required to act on the projectile. A gas, doubtless, is elastic according to its density, and, if permanent in this respect (such as steam or compressed air), could not be generated too quickly to give velocity to a projectile. But with all explosives, the reverse has been shown to be desirable, i.e., provided a given charge will consume in a barrel before the bullet quits the muzzle of the arm. The slower the combustion the greater the velocity communicated to the bullet, the friction in the barrel being greatly reduced. Last year, a public trial took place with a view of testing the new explosive substances. Some very fair shooting was made with wood-powder and gun-felt at 100 yards' range in rifles, the latter equalling gunpowder in accuracy, and the former within 30 per cent. of it. If there is to be any competition this year, it is to be hoped that it will be at long ranges, that being the true test with rifles, reference being made to the angle of elevation and absolute deviation. As already intimated, some further comparative experiments are to be made with Schultze's wood-powder and Reeves's gun-felt, to which we look forward with interest, and the results of which we shall place before our readers.

#### THE LATEST PHASE OF THE ARMOUR-PLATE QUESTION.

T is not many months since we noticed the giant strides made at the Atlas Steel Works, Sheffield, of which establishment Sir John Brown is the head, in the development of the armour-plate question. Upon that occasion we described the rolling of the Upon that largest armour plate ever produced. Produced, too, not merely nor only as a specimen plate of the once-in-a-way type, but as a sample of practical work, which could be repeated day by day for any length of time, so long as orders were on hand for such plates. This plate, we may add, measured 20ft. long by 4ft. wide and 15in. thick, its weight being about 21 tons. But, besides the question of length in these plates, there was one of breadth, which was of great importance, inasmuch as by increasing the breadth of the plates, the joints, which were so many lines of weakness, were reduced in number, and the structure thereby greatly strengthened. It was in view of this circumstance that the short time, we defer a further reference either to its composition or its special per-

prominent the important point of whether the entire face of the shield or casemate could be constructed of one entire plate; in fact, with an unbroken front. The most eminent witnesses hesitated to affirm that this could be effected; and, at the time, the principal practical man at the Atlas Works denied the practicability of producing a perfect plate 12ft. by 8ft. in superficial area, and some 5in. or 6in. in thickness. It was, however, a difficulty to overcome which promised to be greatly to the advantage of some one or other. Considerable attention was given to the subject by the Atlas firm, and, in time, the theoretical solution of the question was embodied in a patent taken out by Mr. J. D. Ellis, the managing director at the works. On the 19th of last month, its practical solution was embodied in a perfect armour plate 16ft. long, 8ft. 6in. wide, and 5in. thick.

The great barrier hitherto experienced in rolling such broad plates has been the insuperable difficulty of heating wide masses When the pile was of iron in the furnace. more than 6ft. in width, the waste and burning of the metal at the sides was excessive, and there were no means of controlling this detrimental action. Mr. Ellis, however, has overcome this difficulty by an ingenious method of manipulating the slab. His process is to make a narrow pile by rolling the iron first to a length equal to its future breadth, and then, by turning it half round, the length is made to become the breadth. The pile is rolled down and out in the direction of its previous breadth until the full length and proper thickness of the armour plate is attained. By this method of treating the pile, Mr. Ellis also obviates another difficulty which has hitherto been experienced in expelling the slag or cinder from the intermediate spaces between the slabs constituting the plate.

The production of a plate under the new process was regarded with considerable interest by Government, which was represented on the occasion to which we have referred by Colonel Inglis, R.E., Captain Harrison, R.A., Captain Alderson. R.A., Lieut. Ellis, R.A., and Lieut. English, R.E. The pile consisted of five slabs, each 7it. by 6ft., and 34in. thick, forming a mass of 60 cubic feet, and weighing 14 tons. This mass was gradually heated to a welding point during 16 hours. On the day in question, the furnace door was opened at 25 minutes past 12 o'clock; the mass was soon under the rolls, through which it was passed backwards and forwards four times. After this, it was turned half round, and again submitted to the action of the rolls, until, at 10 minutes to 1 o'clockjust five-and-twenty minutes from the commencement of the operation—the plate was turned out finished. The process of rolling this plate was personally superintended by Mr. Jevons, the iron manager of the works, and conducted with consummate skill and coolness of direction. The rolls used are new ones, made expressly for this class of work, by Messre. Claridge, North, and Co., of the Phœnix Foundry, near Bilston. They are grain or soft rolls of cast iron turned down to the required dimensions, namely 11ft. long in the barrel (18ft. over all), and 34in. in diameter; their weight is 19 tons each. We have already given the dimensions of the finished plate, and need only add that plates 8ft. in width and 20ft. in length could as easily be produced at the Atlas Works. This result redounds highly to the credit of a firm which has always stood first in the production of armour plates, and has ever kept pace with the requirements of these advanced times.

Before concluding, it may not be inappropriate to notice the first instance of armour intended for the plating of the ship of a foreign Power, being tested by the British Admiralty officers. This circumstance occurred on board the target ship "Thunderer," at Portsmouth, on Thursday week. The trial was made with a plate selected from a number manufactured by John Brown and

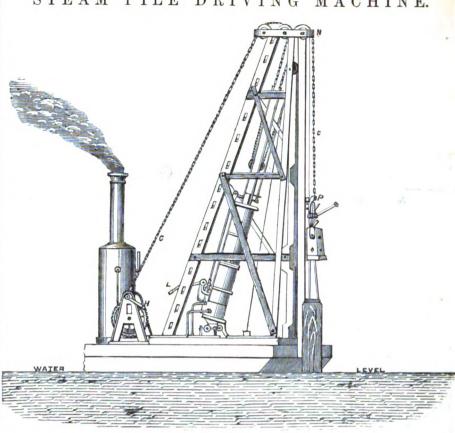

Co. for the Imperial Austrian screw ironclad frigate "Lissa." The dimensions of the plate were 12ft. 6in. in length by 3ft. 6in. in breadth, and 6in. in thickness. The plate was bolted on the backing on board the target ship in the usual manner, and fired at with spherical shot and 13lb. powder charges at the fixed distance of 30ft.; in fact, the conditions of the trial were precisely similar to those observed on the trials of plates for Her Majesty's ships. The five shot indents pro-duced on the diagram had depths respectively of 1·8in., 2·15in., 1·86in., 1·22in., and 2·09in. The cracks in the iron across the indents were exceedingly minute, and the maximum depth was only 7-8ths of an inch. On the back of the plate, the greatest extent of the bulge was 2 in. In its area, its longest diameter was 2.5in., and its shortest 2.4in. greatest depth of crack-longitudinal onlywas 1.5in., and width §in. Upon an examina-tion of the plate after it was taken down from the bulkhead backing, the excellence of the manufacture and also of the iron with which the plate had been built up were still more clearly proved than had been shown by the outer surface of the plate; a result upon which we further congratulate the Atlas Works.

### NOTES ON OUR NAVY.

IN a previous notice, I commented on the I impropriety of introducing the twin screw system in our war ships, before its advantages and disadvantages had been well gauged by experiments of a sufficient scale. At that time, I based my convictions on theory only, as I had never sailed in a vessel fitted with twin screws. Recently, however, I have had the most favourable and continued opportunities of conducting the necessary trials. I find that my apprehensions are more than realized, and the sooner such structures are discontinued the better will it be for the reputation of the Admiralty and the welfare of the country; for both will be seriously compromised if the building of such ships be persisted in. As I have already pointed out these many disadvantages, a repetition here will not be required. There is one important defect which I then omitted, and which is worthy of the most serious consideration of the advocates of the twin screw, as it assails them on the most important of their claims to superiority. I allude to the hopelessly defective steerage in a seaway, when running dead before the wind, and, worse still, when abeam. At first, I attributed a part of this to the helmsman, but repeated trials convinced me that the whole was due to the unequal velocities of the screws, as they worked in the air or water. The racing on the former taking place, was something marvellous, as no governors were fitted to the engines. When the starboard screw was deeply immersed, the ship's head fell off to port before the helm had the slightest effect; and ere it could be brought to its normal position, a roll in the opposite direction upset all previous calcula-

It is with regret I assert that we have sadly retrograded in the construction of small craft since Mr. Reed has been in power. In lieu of the safe, dashing, handy corvette of 1856, we have low unsafe rolling boxes of machinery. I have frequently counted their rolls when at anchor, in an ordinary trade swell, and have registered twenty-one in a minute. And such rolls! First the deck visible, and then far down the bilge. I believe the Admiralty are now thoroughly awake to their demerits, as two of the most unsafe have recently been sent to the penal settlement of Bermuda, to end their inglorious career amidst the coral reefs of that group, or to rot at their moorings off the dockyard. As one is constructed of iron, this leads us to that gigantic structure, the Bermuda dock, about which we have heard so much, and which is not yet across the Atlantic.

STEAM PILE DRIVING MACHINE.

appears to be a fatality about foreign floating docks, from which I trust this will be The one at Callao upset with a exempted. Peruvian frigate inside, and 250 men perished. That at St. Thomas sank in the hurricane of October, 1867, and still blocks the harbour up, in defiance of the skill of American divers. The reason assigned for sending out the The reason assigned for sending Bermuda dock is the porosity of the stone which forms the islands. Allowing that stone could not be cemented sufficiently close to keep the water out, is there any reason why a shell of iron should not have been riveted around the sides and bottom? Such a structure would have lasted our generation, and it is hard to say if the next will care about preserving Bermuda, for they will require a similar place on their own eastern seaboard, to keep a power in check whose ambition will sooner or later cause us trouble.

#### STEAM PILE DRIVER.

T would be suggested to anyone who had watched the process of driving piles by hand labour, that it was precisely one of those mechanical operations certain to be effected ultimately by the aid of steam. Anything more monotonous can hardly be imagined than the successive winding up of capstan or winch and the corresponding falls the monkey. In addition also to the monotonous character of the task, is the serious loss of time. This latter consideration has probably been the chief cause of steam being applied to substitute manual labour in pile driving, since time and money are now synonymous terms. Where the ordinary pile driving engine is employed, the operation consists in raising the monkey or ram to a certain height, and allowing it to fall freely upon the head of the pile. The The force of impact imparted to it, and by virtue of which it drives the pile, is evidently a compound of the weight of the ram and the distance or space through which it falls. But, besides the mere force of impact, which it is scarcely possible to determine with accuracy,

fulfilled in order to drive piles with despatch and economy, and the frequency of the repetitions of the blow must be had regard It might be imagined at first sight, that, provided the weight of the monkey, the fall, and the number of blows were constant, the results would be equally true for the same description of ground, and would be perfectly independent of the time occupied. In other words, that it would be of no con-sequence whether the blows were given quickly or slowly. This conclusion, although theoretically correct, is practically utterly fallacious. Experience has demonstrated fallacious. Experience has demonstrated that, cæteris paribus, the rate of descension of the pile is proportional to the number of blows given, and that in certain substrata blows given, and that in certain substrata the ratio is as high as the double. Let W represent the weight of the monkey, H the fall, and N and N  $^1$  the number of blows given in a fixed time. The descent of the pile will be proportional to W  $\times$  H  $\times$  N, and supposing W and H to be constant, then it will be proportional to  $\frac{N}{N_1}$ . That the frequent

repetition of blows is conducive to rapid pile driving can be readily demonstrated. If we imagine a pile to be forced a if we imagine a pile to be forced a little distance into the ground by a series of blows, and left in a state of rest for a short period, perhaps for a few minutes only, the ground which has been loosened all about it becomes close and tight again. It is, in fact, quite possible for the ground to reseattle in such a manner as to offer a to re-settle in such a manner as to offer a greater resistance to the entry of the pile than before it was disturbed at all. On the contrary, when the blows are given in quick succession, the earth has not the time to reclose around the pile, but becomes more and more loosened in its vicinity, until it is almost in the same position as it would be in a well, all that is necessary being to apply an amount of force sufficient to cause the pene-tration of the point. In soft sandy soils the rapid method is productive of very successful results.

It must be admitted that, hitherto, the usual calculations upon which are based the the, and there are other considerations affecting the principles of pile driving, take no notice of the ratio between the time and the number

of blows given in that time. The weight of the ram has always been regarded as the chief operating cause. This, to a certain extent, is a correct consideration, but its effect may be greatly exaggerated. A heavy ram in falling through a given height will produce a violent shock of impact upon a pile, but beyond certain limits the practical result accomplished is not proportional to the weight. With engines worked by hand it must be kept in view that the labour increases directly with the weight of the ram that has to be lifted. There is also considerable danger of damaging and bruising the head of the pile in instances, where, owing to either the weight of the ram or the great fall, the impact is rendered too violent. About twelve hundredweight may be taken as a limit that should not be surpassed without good reasons, and in many cases a somewhat lighter ram will prove more effectual as well as more economical. The fall is a variable quantity, being a minimum at the commencement of the operation, and a maximum at the termination, except where the piles are so long that splicing is necessary. The perfection of a pile driving engine would be one that would give the small blows with the same velocity and intensity as the larger, that is, which would never vary in impactive force throughout the whole opera-tion. A fall of 20ft. will be found the greatest that should be employed when the blows are given rapidly. A comparatively light ram, with blows in quick succession, has been proved to be more effective than a heavy monkey striking blows at long intervals.

The name of M. Chrétien is known to our readers as the inventor of a particular description of steam crane, which was exhibited at the Paris Exposition last year, and illustrated in our columns. That gentleman has now turned his attention to the invention of a steam pile driver, in which the principles already adopted by him in cranes and gantries are adhered to, so far as the different purposes for which the machine is intended will permit. It is represented in the accompanying engraving, and is of a simple and practical character. By its means, the intensity of the blows can be increased and reduced at pleasure, and the rapidity, when the fall is small, can be augmented to so many as one every second. This velocity depends altogether upon the steam power applied, and, like every other example of the application of that potent agent, is in exact proportion to the capacity of the boiler, or the amount of steam generated in a given time. The machine is set in action by the time. The machine is set in action by the lever L (see figure), every movement of which corresponds to a blow given to the pile, while, at the same time, the person in charge, by a turn of the winch handle H, causes the chain to unroll sufficiently to follow the ram in its descent after the pile, so that the ratio between the fall and the sinking of the pile is practically constant. This is one manner of using the machine, but it can also be employed to drive with a fall equal to the total height of the crosshead N, above the pile. In this case, the ram is drawn up to the top, disengages itself, and falls upon the pile, when it is seized by the hook P, and again ascends, to repeat the same operation. This ascends, to repeat the same operation. machine was recently employed, with great success, in driving the piles for the founda-tion of the syphon sewer laid under the Seine, near the Pont d'Alma, at Paris. In large works, where piling has to be adopted upon an extensive scale, there is no question of the superior economy of steam compared with hand labour; but unless there is plenty of work to be got through, and in a short period, the cost of these engines will always prove a drawback.

#### A VELOCIPEDE RAILWAY.

PNGLAND, France, and America are at to play against particular parts of the collopresent enjoying a quiet triangular dion surface, and to produce markings of game at velocipedes. In France, they have unequal action. The remedy is to have as

had races and matches; in America, they are doing—or trying to do—the thing on the tight rope. This is all very well for French excitement and American sensationalism, but it don't suit our English sober-going notions. So, we turn to the practical, and utilise this newly-revived system of locomotion for useful purposes. We propose velocipede railways—at least, one candidate for Bedlam amongst us does. Here is the sum and substance of a recent application to the Lord Chancellor for a patent which we found the other day in the Patent Office:—
One single line of rail is arranged in the middle of the roadway. The rolling stock is constructed with four bearing wheels, with double flanges, all in one line in the middle, underneath each carriage, instead of having bearing wheels placed on each side. Traversing screws and gear are employed for shifting the wheels laterally relatively to the body of the carriage, until the load is perfectly balanced upon the wheels. The perpendicular position is preserved by the addition of one or more wheels on each side of the carriage, so arranged, by working in slots, as to run freely upon the road, without bearing any part of the weight of the carriage, except when the carriage inclines to one side or the other.

Truly, the inventor expects and hopes to become a great man, but he must be a wise one first; and, if he is, he will consider the magnificent impossibility of his project before he expends another legal coin of the realm upon it.

#### IMPROVEMENTS IN PHOTOGRAPHY. No. III.

LREADY we have given notices of the chief features of interest in the year books of two of the photographic journals, so that only the almanack published by the proprietors of the "Illustrated Photographer" now demands attention. This annual contains one very valuable article by Major Russell, on the deterioration which so rapidly takes place in the working of the nitrate of silver bath solution, which is the most expensive of those used by photographers. More-over, the quality of the pictures gets worse as the nitrate bath loses its first purity and sensitiveness. It is well known that organic impurities in the nitrate bath cause fogging and other faults, and that these impurities may be removed: so this part of Russell's contribution need not now be considered. Another fault is caused by the liquid acquiring the power to form a colour-less crystallizable combination of nitrate of silver with iodide or bromide of silver, and it has long been thought that the evil is due to the complete saturation of the bath with iodide or bromide of silver. Major Russell brings forward experiments to show that this time-honoured idea is wrong, and to establish the following principle, which is a great addition to photographic knowledge:—
"The nitrate of silver can combine with a haloid salt of silver only when the power of the bath liquid to hold the former in solution is limited; or, in other words, when this liquid approaches to a certain degree the point of saturation with nitrate of silver. This effect is produced in practice by great strength of the nitrate solution, by the presence in it of alcohol and ether, which tend to precipitate the nitrate of silver, and of These nitrates other than that of silver. unfavourable conditions to good working assist each other; thus, the stronger the bath, the less alcohol in it will set up the crystallizing action." The bath, therefore, should never be made stronger than is necessary, and great care should be taken to keep it as free as possible from alcohol and ether. Another fault is often caused by the lower ledge of the glass dipper projecting too far, thereby causing ripples of nitrate of silver

small a ledge as possible, or use a dipper of silver wire, and to lower the plate gently, though without halting.

A good suggestion, likely to enable photo-

graphers to obtain natural clouds in landscape pictures, is made by Mr. Thomas Sutton, B.A. He recommends that the stop before the lens, instead of being placed vertically, as usual, shall be inclined at an angle of about 35deg. to the vertical, the upper part of the stop being then further from the lens than the lower part. If the pencils of light from the object be traced through a landscape lens furnished with such a stop, it will be seen that the amount of light from the sky, which would otherwise fall upon the plate, is much lowered. The suggestion appears to be very simple and valuable, but Mr. Sutton omits to state how he has found it to answer in practice. The almanack also contains a useful article, by Mr. J. C. Leake, with small cuts illustrating some of the art principles which should be borne in mind by landscape photographers. There is a contribution by Mr. George Dawson, M.A., who gives practical information upon the dry processes; and there are articles by Messrs. E. B. Fennessy, W. Willis, C. Russell, R. H. Courtenay, A. H. Wall, and T. Attwood. This almanack H. Wall, and T. Attwood. This almanack differs from its competitors in the fact that it is illustrated with many groups, and standing and sitting figures of ladies and gentlemen, so as to be useful to photographers who wish to place sitters and standers in graceful positions, other than the stereotyped attitude, wherein the person represented is seen nervously grasping the top of an uncomfortable-looking straight-backed chair. A table of temperatures in the beginning of the almanack tells the readers that milk freezes at 230deg. Fah., which of course implies that the editor melts his milk every morning for breakfast by the aid of a small blast furnace. The same table says that phosphorus melts at the zero of the Fahrenheit scale, that wine freezes at 120deg., and that water boils at 112deg. As a whole, the almanack of the "Illustrated Photographer" is worth having, and its graphotype illustrations are interesting, though they show that as yet this process cannot compete in quality with good engraving upon wood.

### ELECTRICITY AND TELEGRAPHY.

ON January 10 an interruption occurred on the Corfu and Otranto cable. The Telegraph Construction and Maintenance Company's steam ship "Chiltern" was specially despatched for the repairs, and communication was restored on the 25th nlt.

In consequence of the accident to the "Calcutta," the Persian Gulf expedition was necessarily delayed. It is now determined upon to postpone the submersion of the cable until the latter part of the year, after the cessation of the monsoon. The "Tweed" will probably leave about the end of May, and the "Calcutta" as soon after as the repairs rendered necessary will allow. The latter vessel, now at Plymouth, has been temporarily repaired by divers, and her cable being coiled on shore, so as to render her fit to be taken into dock, and to allow of the damage done by the collision to be repaired. This is a matter that will not take so long as was originally thought. The steamer "Caroline," belonging to Mr. Henley, has been chartered, and is now at Plymouth, and so soon as she is fitted up with the necessary machinery, she will proceed to pick up the seventy miles of cable paid out from the "Calcutta" after

The Mediterranean Extension Telegraph Company have issued a favourable half-yearly report. In consequence of the laying of the new direct line from Malta to Alexandria, and of the new proposed line from Sues to Bombay, it is in contemplation by them, as a just measure towards the public, and in their own interests, to lay a second cable from Malta to Sicily, at a cost of

Digitized by Google

about £11,000. The length is but short, and in view of the greatly improved communication to India, on the completion of the British Indian line, it would be a most unwise policy to trust through communication to one cable only through this distance—a very short, but important, link in our great Indian chain of telegraphic communication. The existing cable has already lasted a long time, and in all probability will last an equal period, but the cost of an additional cable is small in comparison to the enormous advantage of the perfect certainty of a communication free from interruption.

The directors of the United Kingdom and the British and Irish Magnetic Telegraph Companies, as well as all the other companies, are now busily engaged in settling the actual money terms of the transfer of their properties to the Government.

The increase in the Magnetic Company's system during the past year has been 311 miles of wire and three stations, their total being at present 19,275 miles of wire and 513 stations.

The report of the United Kingdom Telegraph Company is as satisfactory as those of the other telegraph companies, and not only shows a large amount of business during the past year, but also good hopes for the future. An increase in their mileage has been caused by erecting new wires, in connection with the new Danish cable, submerged in September last, which gives two cables, to Russia. The one has already been laid to Bornholm; the other will be laid in the spring. As regards this route, "for the short period the Danish cable has been open, however, the directors are satisfied that the current year will prove the expenditure for the erection of the special wire in connection with this cable to have been one of a highly advantageous character to this company."

A cable is in course of construction to be laid from Scotland to Norway. This line will be in connection with this company. It is further contemplated to extend this line to Russia, so that there will then be a duplicate route to Scan-dinavia, Russia, China, and the East. To be ready for the submersion of this new Norwegian cable, which is now in course of manufacture at the works of Mr. W. T. Henley, at North Wool-wich, the company are erecting a special wire.

The manufacture of the French Atlantic cable continues in the most satisfactory manner. main cable from Brest, with its shore ends, and the shallow water cable, with its shore ends, for the United States section, are all gradually proceeding towards their completion. Up to the present ing towards their completion. Up to the present time, about 1,700 miles of the main cable and 450 of the shallow water have been completed. The coiling on board the "Great Eastern" is going on, there being already about 900 miles in the big ship.

The tests of the conductor and insulator prove that the contractors are supplying cable much superior to the specified contract.

The Telegraph Construction and Maintenance Company have issued their report, and held their meeting, when a dividend at the rate of 10 per cent. on the year was declared. The present position of the company is as satisfactory as the shareholders could wish, and during the past year they have executed a large amount of submarine telegraph work, giving a total of 1,971 miles of cable made. The principal works executed are the manufacture and laying of the direct Malta and Alexandria cable, the Tasmanian cable, portions of the French Atlantic cable, and other minor con-tracts. The contract for the Malta and Alexandria line included the purchase of the company's direct overland line from Susa in Italy to Modica in Sicily. and the transference of the old Malta and Alexandria Government line. They report that the new Alexandria line "has been working in a most satisfactory manner, and, like all other cables submerged by this company, far exceeds the specified insulation and transmitting speed."
Under their auspices, and those of the great ship

company, and some capitalists, the British Indian Submarine Company, with a line from Suez to Bombay, thas been brought successfully before the public. The contract is obtained by them, but the profit is a deferred one, which, in the estimation of the directors, is a certain one. They feel that in bringing British India and Great Britain into telegraphic relation is really opening

3,600 miles of cable. The contract with the French Atlantic Company is proceeding in a most satisfactory manner, and as the distance over which the cable extends in the deep sea route from Brest to St. Pierre is nearly identical with that in which the Atlantic cable of 1865-1866 were successfully submerged, the risk, therefore, they consider, is not increased, although the total length of cable is nearly double that of the Atlantic cable. During the past year, their ship, the "Hawk," successfully, and with expedition, repaired the break in the 1866 Atlantic cable—a proof of the certainty and despatch with which this company can repair cables made and laid by them; a fact, also, which will further tend to increase public confidence in submarine telegraph property. They further report that "care has been taken to keep the company's works, at Wharf-road and at East Greenwich, in a perfect state of repair, and improvements have been introduced greatly increasing our power of production." Enough has been shown to prove the satisfactory nature of the company's operations during the past year, and that there is every prospect of the present year being more favourable to the interests of the shareholders, it is sufficient for us to notice the fact that already the company have on hand orders to the extent of 6,408 nautical miles of cable.

NOTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

PRODUCTION OF ROSANILINE WITHOUT ARSENIC ACID -SULPHUR IN GAS FLAMES-A FIREMAN'S PLAT-FORM.

N interesting report to the Société Industriel of Mulhouse, by M. Schutzenberger, gives an account of the manufacture, by M. Coupier, of the red aniline dyes without the employment of arsenic acid. By abolishing the use of this reagent the production of these colours becomes of less cost, and the inconveniences which result from the accumulation of a poisonous residue are avoided. The colour produced is a salt of rosaniline, just as our magentais, but it is conceded that the tint is not quite so bright and pure as that made by employing arsenic acid. The yield of dye, however, is somewhat larger, and the process, as we have said, is cheaper. M. Coupier heats together a mixture of pure aniline, nitro-toluene, hydrochloric acid, and iron filings, this last being employed in but small quantities. A mixture of commercial aniline and nitro-benzol with the same acid and iron will serve just as well, and the colour produced will be the same in each case. We gather from the report, though it is not expressly stated, that about equal parts of aniline and nitro-benzol may be used. The mixture is gradually heated up to 200deg. Centigrade, and the course of the operation is watched by taking a sample of the product occasionally.
When the conversion is complete, the contents of the still are a semi-fluid mass, which, as it cools, assumes the well-known appearance of the solid aniline reds, and may be purified by the usual methods. There are two economic recommendations in this process. The expense of converting half the aniline is saved, and the cost as well as the dangers of arsenic acid are avoided.

A discovery has been made by M. Sallet, somewhat interesting, in these days, to gas examiners and makers. If any solid body be pressed upon the nearly colourless flame of pure hydrogen gas, the flame is seen to be suddenly coloured blue. The cause of this has never before been explained by chemists, but M. Sallet tells us that it is caused by the vapour of sulphur in the gas. As the hydrogen is supposed to be pure, the question arises, whence comes the sulphur. According to our author, it comes from the reduction of sulphates always in suspension in the air, and more particularly from sulphate of sodium. Soda salts, we know, are everywhere present in the atmosphere.

An important auxiliary in extinguishing fires

has been invented in Providence, R. I. It is called the "fireman's platform," is mounted on one truck, and consists of three cylindrical sections which shut within each other like telescope slides, and can be elevated into a tower 50ft. high, wherewith to reach the upper stories of a burning building where the field to a very extensive series of operations in reach the upper stories of a burning building where cables to Australia and China, and will succeed in enhancing the value of all submarine telegraph property, both in the Mediterranean and in the Atlantic. The amount of this contract will be in flames. The sections are constructed of light

concentric rings of wrought iron, so that the whole apparatus weighs only 3,300 pounds. The walls are divided by rounds, which thus form ladders.

#### PARLIAMENTARY NOTES.

YESTERDAY week, in the House of Commons, Mr. CHILDERS brought up the navy estimates, and gave notice that he would on that day week move that the House should go into committee upon them. Mr. OTWAY brought up the army estimates, and Mr. CARDWELL subsequently gave notice that on Monday, March 8, he would move that the House should go into committee upon them.

On Friday, Mr. J. Howard asked the Attorney General whether it was the intention of the Government to introduce during the present session any measure for the amendment of the patent laws; and, if so, whether it was the intention of the Government to embody in the bill the "recommendations" of the Royal Commission (dated July 29, 1864) appointed to inquire into the working of the law relating to letters patent for inventions.

The ATTORNEY GENERAL said there were so many important questions to be dealt with that he was not able to hold out any confident expectation that the Government would be able to deal with that question in the course of the present session.

Viscount Engield asked the Secretary of State for War when the medal promised by the late Secretary of State for War on the 6th of last July to the naval and military forces engaged in the late campaigns in New Zealand was likely to be issued.

Mr. CARDWELL said that the army estimates which had been presented on the preceding day contained a proposal for a sum of money to be appropriated to that object, and the design for the medal would, he believed, be very shortly ready

for her Majesty's approval. Mr. Sykes, in moving for leave to bring in a bill for the preservation of sea birds, said the sea birds of England were gradually disappearing from our coasts, and the object of this bill was to protect them during the breeding season. brought the measure forward in the interests of three important classes of the community-the farmers, merchant sailors, and deep-sea fishermen. The sea birds were valuable to the farmers in destroying worms and grubs, valuable to the merchant sailors by giving warning with their shrill cries in foggy weather of the proximity of rock, and valuable to the deep-sea fishermen because they hovered over the shoals of fish, and so pointed out the places where the fishermen might cast their nets .- Leave was given for the introduction of the bill.

Sir J. HAY called attention to the rule of the road at sea, and was desirous to ask a question of the President of the Board of Trade on the sub-ject. The "rule of the road at sea" he observed was a technical term for certain regulations issued by the Board of Trade for showing vessels passing each other how they were to keep clear of each other, and avoid collision. The rules which had been drawn up on the subject were exceedingly useful. They had been translated into various rule of the road by nearly all maritime nations, and, without sufficient cause, it would not be desirable to meddle with them, but there were two relating to steamers passing each other, "end on," which he thought required alteration—he alluded to Articles 13 and 14 of these regulations. He thought it would be well that the simple rule should be, when two steamers were nearing each other, to starboard the helm to a ship on the starboard bow, and to port the helm to a ship on the port bow. It was very desirable that every precaution should be taken to prevent the risk of collision.

Admiral SEYMOUR concurred in the alteration suggested by Sir J. Hay. There was also another matter to which he wished to call attention. He thought that sufficient stress had not been laid on the question of stopping the engines. In the case of the collision between the Osprey and the

I should enter into the minute and technical points to which the attention of the House has been drawn. I think it will, perhaps, be better for me to read a little memorandum which I made this morning, and which will probably be a sufficient explanation. I understand that the present rule of the road at sea, as adopted by this country, was adopted after the very best professional assistance had been obtained, and after the fullest discussion had been obtained, and after the full statement of the full state secured. The Trinity House, the Board of Admiralty, the Board of Trade, and the judge of the Admiralty Court in England, communicated with the French government on the subject, and both were unanimous in their conclusions. This agreewere unanimous in their conclusions. ment was come to in 1862. Since then it has been considered by the authorities of every maritime state on the face of the earth, and it has been adopted by all of them. The rule of the road agreed to in 1862 is, therefore, at this moment the rule of the road for ships of all nations, and cannot be altered without the concurrence of mations. England cannot now of herself undertake the responsibility of altering this international law. But with respect to the particular point to which the hon. gentleman has called attention, as to the certain rule to be adopted by ships approaching each other "end on," this particular matter has been reconsidered since 1862, and a further explanatory order was issued in July, 1868, when I think the hon. baronet and the gallant admiral were members of the Board of Admiralty, but pro-bably they have forgotten what was done at that time. I understand that their own Board of Admiralty wrote to the Board of Trade and gave their entire assent to the explanatory clause which has been agreed upon, and I think, after that, I may fairly ask why, when they were at the Board of Admiralty they did not endeavour to attempt to remedy this imperfection. I may further state that the Board of Trade have received a large number of pamphlets and suggestions on various branches of this subject, and I believe no two of these pamphlets or suggestions agree. The rules now in force are very simple; and it is hardly possible that any man who is sober, and in his senses, and not panic-stricken, should not be able to learn and apply them. They are taught to all masters and mates of ships, and they cannot have their certificates until they thoroughly understand them.

On Monday Colonel SYKES asked the Secretary of State for War on what grounds he refused to permit the invention of Mr. Groundwater for the readaptation of used musket cartridge cases to be tested, so as to ascertain whether or no a considerable saving might not have been effected in the consumption of cartridges; and if it were not the fact that the machinery used by the Govern-ment was adapted only for the original construction of the cartridge case, and not for its readaptation for service.

Mr. CARDWELL replied that the Director General of Ordance was perfectly satisfied with the present machinery by which this object was attained.

On Tuesday Mr. HANBURY-TRACY asked the First Lord of the Admiralty if his attention had been called to the present condition of the Royal Naval Reserve, and if it was his intention to introduce any measure to increase its efficiency.

Mr. CHILDERS said his attention had not been called in any specific manner to the condition of the Reserve, but that he would state the course which the Admiralty proposed to adopt with regard to it when he moved the navy estimates.

At the same sitting Mr. W. Cowper asked the

First Commissioner of Works whether the large accumulations of refuse from brick-kilns that now covered the green slopes of Hyde Park, near the lower end of the Serpentine, had been placed there in the hope that they would imitate rock-work; or, if not, for what purpose they had been brought

Mr. LAYARD assured his right hon. friend that he had not the slighest intention of cheating him or any one else into the belief that the brickwork was intended for rockwork. What his right hon. friend, with a poetical license, called the green alopes of Hyde Park, formed merely the banks of a very dirty ditch through which fell the outcome of the Serpentine. The brickwork had been placed there simply because it would form a good foundation for the subsoil in which certain shrubs were to be planted.

On Tuesday evening Mr. Alderman Lusk asked the First Lord of the Admiralty whether his attention had been directed to the reports in the public journals of the large quantities of Australian

the favourable statement of his Royal Highness the Duke of Edinburgh in regard to the Australian Preserved meat published in the "Times" of November 2, 1868; and whether, seeing that the preserved meats produced at the Deptord Dock-(according to Parliamentary Return, No. 353, of last Session) cost 11d. per pound, he intended to continue to supply the navy with that manufactured by Government, or to buy in the open market.

Mr. CHILDERS said that so far back as 1865 the attention of the Government had been called to the possibility of obtaining meat for the use of the navy from the Australian colonies at a lower cost than in this country, and inquiry on the subject was made through the Australian Government, but did not end in any satisfactory arrangement. Last before the present Admiralty took office, a certain quantity was purchased and issued to different ships, in order that the epinion of the officers and crews might be taken on the matter. A reply had been received, which, for the most part, was entirely satisfactory, and the Admiralty had ordered notices to be issued for tenders. would have to state, in moving vote No. 2 in the Navy Estimates, the financial result of such an arrangement. This is an important question for our naval authorities, and one upon which we shall have a few practical observations in our

## LAUNCH OF THE "VOLAGE" AND THE "AUDACIOUS."

ON Saturday last, the first of several vessels of an entirely new closes an entirely new class was added to the effective strength of the English Navy by the launch of the "Volage" at the Thames Ironworks at Blackwall. The "Volage," which has several original features with her sister ship the "Active," which is to be launched from the same yard the nex spring tides, is designed by Mr. E. J. Reed, for the purpose of combining great speed with ability to carry a few powerful guns. She is a vessel of the Alabama class, and in the event of war would, like the Alabama, be employed for annoying the commerce of the enemy. As she is intended to remain a long time at sea, it was necessary that she should be coppered, but the well-known antagonism of copper and iron of course required that the metals should not be in contact. To the iron plating, therefore, is attached a wooden sheathing, 31in. in thickness, fastened with iron bolts screwed through the plates, and secured inside with nuts. The heads of the bolts are sunk in the wood, and covered with a dowel, and then the sheathing is iron is thus completely insulated, and, to avoid any chance of galvanic action, the sternposts and the rudder frame are of gun metal. Over all a second sheathing of wood is fixed, by metal screws, which stop short of the iron plate, and on this upper sheathing the copper is fastened. The dimensions of the ship are:—Length between perpendiculars, 270ft.; extreme breadth, 42ft.; depth in the hold, 15ft. 2in.; her burden is 2,321 59-94 tons, and she will be furnished with engines by Messrs. J. Penn and Son, of 600-horse power nominal, an engine power which is expected to drive her at the rate of 15 knots, a rate of speed higher than that of any war vessel afloat; but beside her steam power, she will have the advantage of a full rig, so that she will be able to economize her coal. Her armament will be six 61-ton guns on her upper deck, a 64-pounder on her poop, and another on her fore-

On the same day there was also launched from on the same cay shere was also manched from the building yard of Messrs. R. Napier and Sons, at Glasgow, the "Audacious," a twin-screw iron armour-clad frigate for the Royal Navy. The "Audacious" has also been built from the designs of Mr. Reed, and is of the following dimensions Length between perpendiculars, 280ft.; breadth, extreme, 54ft.; depth, moulded, 36ft.; burden in old measurement, 3,774 19-94ths. be fitted with twin-screw engines of 800-horse power collectively. The framing consists of a strong, but light, combination of longitudinal and transverse frames, with a double bottom, formed by working upon this framing an inner and an of plates, the whole being strongly riveted together and made thoroughly watertight. The usual transverse watertight bulkheads are likewise fitted throughout the vessel, these being provided with sluice valves and watertight doors, &c. The decks have a covering of steel plating, riveted to the beams beneath the usual planking,

against penetration of the decks by plunging shot The armament is intended to consist or shell. of ten 121-ton guns-six on the main and four on together with four 64-pounders ck. The guns will be protected by the upper deckon the upper deck. an armour-plated battery, occupying the central part of the ship, and so arranged, by projecting slightly beyond the vessel's upper works, as to afford ample space for conveniently working them, at the same time giving a clear range for firing, not only in broadside fashion, but also right ahead or right aft, if required. The armour-plating is so disposed as effectually to protect the most vulnerable parts of the vessel. A broad belt of 8-inch armour is wrought on in the vicinity of the water line (except at extremities, where it is gradually lightened), and other parts of the sides and the battery are covered with 6-inch armour, having a backing of East India teak, 10in. thick, supported by a double thickness of plating, 14in. collectively with girders and internal frames.

Mesers. Napier have also in hand, and will launch shortly, a sister ship to the "Audacious," to be named the "Invincible." They are also constructing the "Hotspur," a vessel on an entirely new principle as regards the British navy. Its chief novelty consists in a fixed tower or turret, strongly armour-plated, to protect the armament, which, is at present intended to consist of one large gun, to be trained from port to port of the turret by a revolving turn-table.

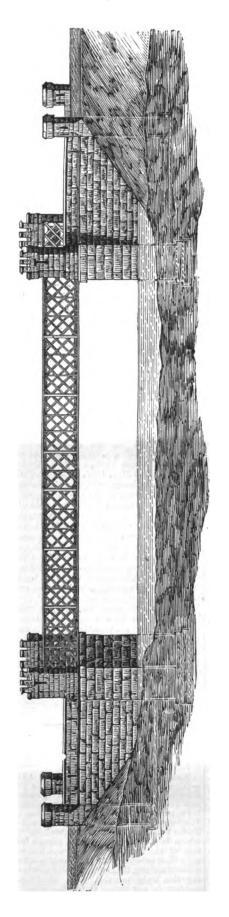

#### LIQUID FUEL

AT a recent meeting of the French Academy of Sciences, M. H. Sainte-Claire Deville continued the description of his researches on petroleum, undertaken at the Emperor's expense. experiments show that the heavier and more viscous mineral oils are the fitter they are for fuel. use in brick furnaces, he observes, is a problem already solved, the method consisting in letting out the oil from a reservoir through a stop-cock on a brick floor, placed behind a clay screen pierced with holes for the admission of the air intended for For this clay screen, M. Sainte-Claire combustion. Deville substitutes a thick cast-iron one. An apparatus of the kind described was placed on board the imperial yacht "Puebla," and was found to answer the purpose perfectly, being employed on a boiler producing steam enough for a 60-horse power engine. About May, 1868, M. Sainte-Claire Deville obtained permission to try his furnace on an engine on the Strasbourg Railway, where it was important to reduce as much as possible the bulk of the apparatus, and to suppress brickwork, since the constant shaking of the engine would be apt to get it out of order. Another difficulty was the quantity of oil, enormous in regard to the small surface at disposal, to be consumed in order to produce steam to the amount of 300-horse power. These difficulties were overcome by substituting cast iron for brick, and by artificially increasing the surface of evaporation, without enlarging the dimensions of the fireplace. Hence the apparatus intended for a locomotive simply consists in a fireplace so arranged as to present the largest possible surface to the action of The sole of the furnace may be of copper. heat. attached to the boiler, and inwardly kept moist The grating is provided with a series with water. of holes, through which the oil flows. This fuel gives no smoke, and does not emit sparks; the consumption of oil, at the rate of 60 kilometres per hour, was at the rate of 4.70 kilogrammes per kilometre.

WE understand that the visduct over the Holborn valley will be opened to the public in July or August

THE MANUFACTURE OF WATCHES AND CLOCKS THE MANUFACTURE OF WATCHER AND CLOCKS
—A most interesting and instructive little work
describing briefly, but with great clearness, the rise
and progress of watch and clock making, has just
been published by Mr. J. W. Benson, of 25, Old
Bond-street, 99, Westbourne-grove, and the City
Steam Factory, 58 and 60, Ludgate-hill. The book,
which is profusely illustrated gives a full descripwhich is profusely illustrated, gives a full descrip-tion of the various kinds of watches and clocks, with their prices, and no one should make a purchase with their prices, and no one should make a purchase without visiting the above establishments or consulting this truly valuable work. By its aid persons residing in any part of the United Kingdom, India, or the Colonies, are enabled to select for themselves the watch best adapted for their use, and have it sent to them with perfect safety. Mr. Benson, wholds the appointment to the Prince of Wales, sends holds the appointment to the Prince of Wales, public journals of the large quantities of Australian riveted to the beams beneath the usual planking, and other preserved meats that were offered for thereby imparting great longitudinal strength to age stamps, and we cannot too strongly recommend the vessel, besides affording the necessary security it to the notice of the intending purchaser.—| ADVI.

## BRIDGE OVER THE RIVER DULNAIN-HIGHLAND RAILWAY.

BRIDGE OVER THE RIVER DULNAIN—HIGHLAND RAILWAY.

WE recently illustrated one of the numerous bridges by which the Highland Railway is carried over the rivers and streams that intercept its course. We now give another example of these structures—that of a bridge of 80ft. span, crossing the river Dulnain, a mountain stream near Grantown. It is given as a specimen of a substantial bridge of this size. Length, 148ft.; height, 27ft. Cost per lineal foot, £22 5s. 6d. The cost was—masonry, £2,238; ironwork, £1,060;—total,£3,298. On the Central Railway of the Highland system, from Dunkeld to Forres, 104 miles, being a single line, there are 8 viaducts, 126 bridges over streams, and 119 public and accommodation road bridges. On the whole system there are only three timber bridges, which Mr. Mitchell, the engineer of the line, was forced to adopt chiefly with a view to save time, but these are very substantial of their kind. All the other bridges are constructed of stone, and where iron is adopted the piers are in general constructed of masonry. The iron bridges on all these lines were constructed by Messrs. Fairbairn and Sons, of Manchester, for about £20 per ton on the average, and are admirable specimens of workmanship in this department.

## ON A NEW ANEMOMETER.\* By Mr. Wn. Oxley.

THE anemometer which I am about to described has been constructed with the object of supplying at a low cost, an accurate, durable, and effective instrument for measuring the direction and force of the wind. So far as I know, there is no other anemometer that gives so many advantages at anything near the same moderate money value. The apparatus is composed of two parts—the one The apparatus is composed of two partsthe anemometer proper, the other a contrivance for receiving the papers, on which the registrations are recorded. As to the anemometer itself, it is a circular box 11in. diameter, and 21in. deep, which moves freely on its centre on a pivot at the top of a rod fixed firmly into a foot plate, so as to prevent oscillation. The box is horizontal, provided with a oscillation. The box is horizontal, provided with a space on one side, in which is placed a well tempered steel spring, which gives a range of 2\frac{3}{2} in. from zero, to what represents 40lb. pressure on the square foot. To this spring is attached a brass rod or rack, which works the pinion, on the axle of which are placed two fingers, one live and the other dead. These fingers move according to the pressure given (or movement of the pinion), and thus the force is shown by looking at the dist plate and the force is shown by looking at the dial plate, and the figure to which the live finger points shows the present force of the wind, whilst the dead finger is opposite the figure, showing the maximum pressure that the wind has attained during a given period. This is effected by a small pivot or pin at period. This is effected by a small pivot or pin at the point of the dead finger, projecting above the live one, so that as the live finger is forced by the live one, so that as the live finger is forced by the pressure it carries the other with it, and leaves it at that point if the wind decreases. In front of the spring in the space already referred to, is a small disc attached to a rod, on which is placed a wind plate of 6in. square. This plate is kept to the wind by a vane on the opposite side of the circular box, and as its area is just one-fourth of a square foot, the graduated dial figures being multiplied by four, gives the same result as though the plate were a gives the same result as though the plate were a foot square. This size of plate gives lightness, and foot square. This size of plate gives lightness, and reduces the friction to a minimum. The working parts of the instrument are protected from the weather by a glass lid or cover.

Having thus described the anemometer proper, which shows the force of the wind, I will describe how it makes self-records in a permanent form, and shows the range and direction of the wind at the same time. A pencil is attached to the movable rod holding the pressure plate, and moves backward and forward with the plate. The point of the pencil, which is vertical, rests on the paper, and whilst it has the lateral motion referred to it moves in a circular form, as the anemometer moves with the wind. The papers, which are 10in. in diameter, fit into a horizontal recess, placed belew the rod about 2in. under the anemometer. These papers can be changed daily, and measured by a prepared scale, and thus are permanent records of the force, range, and direction of the wind. If the maximum finger registered the force of a storm to be, say, 30lb. on the square foot, the pencilling on the paper would show, when applied to the scale, the blast came.

ELECTRIC TELEGRAPHY IRRESPECTIVE OF TELEGRAPHIC APPARATUS.

By Mr. E. G. BARTHOLOMEW.

A T a meeting of the Society of Engineers, held A March 1, 1869, Mr. F. W. Bryant, President, in the chair, the following paper was read:—The extent of this interesting field is such that it is not attempted within the limits of a paper to enter fully into every point of detail which the subject embraces, and the author has, therefore, deemed it sufficient for the purpose to select such features as either in his estimation present difficulties to the less initiated, or contain within them grounds for discussion. He is aware that many nected with every subject, which, to those whose every-day life is more or less associated with it become matters of course, are nevertheless to many replete with that which requires explanabut as it is hoped such points will crop up tion. in the course of our discussion, he is content to confine himself for the present to what appears to him worthy of notice. It may be further that matters which possess interest, and nothing more, have been avoided; and, moreover, that as it would have been impossible to do justice to the subject of telegraphic instruments and apparatus upon the present occasion, any allusion to them in respect either of their construction or use has been omitted. The allusion to a galvanometer in connexion with inductive charge and discharge has been necessary for elucidation

The subject may be divided into the two branches which appear to be both obvious and necessary, since each branch contains facts totally distinctive and peculiar to itself; these branches are: telegraphy as applied to land lines, and telegraphy as applied to submarine lines. There is also a third division of the subject—subterranean telegraphy-which occupies, as it were, a middle position between these two, and which is better considered in connection with submerged

The development of land telegraphy had, until within the last four years, attained a decidedly higher stage than had submarine telegraphy. The experience gained in the one had been greater —the subject did not in itself present so many difficulties—and it did not involve a knowledge of certain physical facts which it was evident, even in its earlier days, the latter necessitated, and which became more obvious as the subject progressed. It is mechanical knowledge which assists us the most in the construction of a land line, whereas the manufacture and submergence of a telegraphic cable involves, besides that in a much higher degree, an acquaintance with many chemical facts, and a knowledge of the laws by which electricity is governed, to a much greater extent than is necessitated in the former case.

First, with respect to land lines: the conductor demands special attention. If a completed line of telegraph be compared to a "permanent way," the conductor or line wire represents the "metals." It is usual, or at least desirable, to proportion the weight of the rail per yard to the traffic expected and it is equally necessary that the conductor in a line of telegraph should be proportioned to the work it has to perform. It must not, however, be exactly proportioned, as will be seen from a further consideration of the subject. The duty of the conductor is to convey the electric current at all times when required, and under all circumstances which may arise, without opposing unnecessary resistance to its progress. A certain amount of resistance is unavoidable, but when this becomes excessive it will produce a variation in the carrying capacity of the wire under differing atmospheric conditions, besides causing uniformly indistinct signals, unless the undesirable alternative be adopted of increasing the battery power in order to compensate for, or overcome, the resistance.

The general question of Resistance (R) is one of serious moment, and of great interest in all electro-telegraphic matters, and although this remark more fully applies to submerged conductors, yet it must by no means be lost sight of

in open wires.

(R) is dependent upon three conditions: the length of the conductor, its sectional area or diameter if round, and the material it consists of. All substances are conductors of electricity to a certain extent, and all substances resist its passage to a certain extent. The two characteristics are the converse of each other; those which conduct the best resist the least, and vice versa. But a worse conductor may be made equal to a better by increasing its sectional area, or its weight per ously wet, that any appreciable loss of current mile. Thus; the conductivity of pure copper is takes place. This is supposing the insulators were

about eight times that of iron, but an iron wire of 3-inch will equal in conductivity a copper wire of .1-inch, from which it appears that (R) is in direct proportion to the area of the cross section. Again, (R) being in inverse proportion to the length of the conductor, a line of one mile of iron wire will equal in (R) a line of eight miles of copper wire, their diameters being the same.

There are several reasons why, in suspended lines of telegraphy, galvanised iron wire has become the universally adopted material for the conductor. It is less expensive than copper-it will bear a higher strain without breaking-and it is not subject to rapid deterioration. are two tests which the wire should undergo before being suspended—that is, if it is a solid and not a stranded wire which is to be employed; a short sample from each delivery should be held firmly by one extremity, and a narrow streak of some black pigment should be drawn ink down it upon one side from end to end in a straight line. The free end being then atto a cross handle, the wire should tached twisted in the same direction until it breaks; the number of twists per foot can then be counted by the black spiral formed. A good No. 8 wire will stand from 20 to 40 twists per foot. But the most necessary test to which a wire can be subjected is that of longitudinal strain. This must not be confined to short lengths. The quality of the iron may be good, but from want of care in making the welds there may be faulty places, and if the sample subjected to this test happens not to contain a weld, it may pass muster. The straining of a sample will prove the quality, but in the erection of a telegraph this is not sufficient. In this case, the whole length of wire, after being drummed out, should be tested in sec tions of from a quarter of a mile upwards, according to circumstances. The strain should be applied until the wire ceases freely to elongate, long before which period all bad joints and faulty places will have given way, and having stood this strain, the wire will be found to have lost all its "spring," and to be more convenient for handling. In this state it is said to be "killed."

With respect to the gauge of the wire, it has been shown to depend upon the length of the circuit of which it forms part. No doubt, in view of the law of R, every different length of circuit might have a different sized conductor, but other considerations step in. Suppose a wire to be just sufficient in its capacity for its work when newly it is evident that directly it becomes reduced in size, owing to oxid sation, it becomes too small; more battery power must then be applied to overcome the increased R. Again, as every instrument inserted in a circuit adds very considerably to the R of the whole, it is obvious that the addition of a single instrument to a circuit already carefully calculated cannot fail to be detrimental. But, lastly, if a wire be only just detrimental. But, lastly, if a wire be only just large enough for its work in dry weather, cr when the line is well insulated, any circumstance which diminishes the insulation—that is, which the causes leaks for the escape of the current-will increase the tendency of the current to leave the line wire to a greater extent than if the capacity of the line were ample. This latter point needs some explanation. The fundamental principle which should govern the construction of every electric telegraph is, that the battery current shall be compelled to traverse the entire circuit without loss or unnecessary hindrance. Electricity is a swift agent, but even electricity will save itself unnecessary journeys when it can. If it detects en route a loophole, however minute, it will escape in a greater or less degree, the degree being proportionate to the facility for its escape. This is indeed a popular way of regarding R; the largest amount of electricity will travel by the route on which it meets with the least R. If, then, the conductor be of ample area, the facility it for the passage of the current along itself will be greater in proportion to any given fault or faults than if it be only just sufficient; and therefore the divergence of the current from the line will be

Glass, earthenware, porcelain, ebonite, are all exceedingly low conductors of electricity, but when their surfaces become moist the moisture Rain water is pure water, or nearly so, conducts. when first it falls, and in this state conducts \$377 millions of times less than iron; it is, therefore, only when the length of a line is such that several thousand insulators, or points of support occur throughout it, and when all these are simultane-

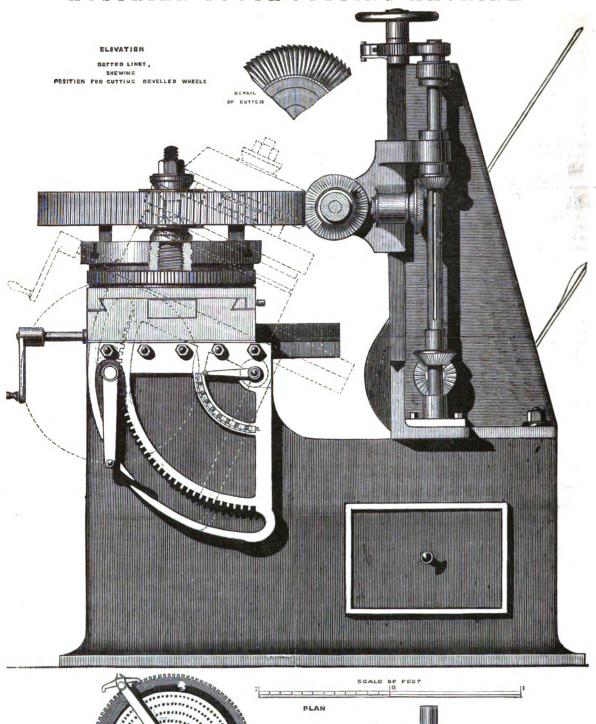

free from dust when wetted, for if dusty, or sooty, and then wetted, the loss is greatly more apparent. In the neighbourhood of large towns, and especially in the vicinity of certain manufactures, the loss is also far greater, owing to the salts with which the air is charged, and which the water absorbs. The importance of these well known facts cannot be over-estimated. If the R of the line, and the joint R of the faults be equal, then half the current is lost. The law of electric currents, in respect of diverging paths, is that the amount of loss is in inverse proportion to the R of the paths. Upon lines where several conductors are attached to the same supports, the dust and moisture which accumulates, not only upon the insulators but upon the surface of the wood between them, affords a path along wheh the electricity will creep, if possible, from one wire to others. it will readily do if the insulators are not kept clean, since two or more wires present less than one. This creeping to other wires should be prevented as much as possible, for it will produce upon them signals not intended for them, thereby causing confusion. "contact." It may be ent This is called "contact." It may be entirely removed by attaching a wire, called an "earth" wire, to each insulator support, and letting it pass down the pole into the earth, it acts by being a far less resisting medium than the damp surface of the wood. The wire may be with advantage extended upwards as well, and terminated in a point projecting above the pole; it will then act as a protection against lightning.

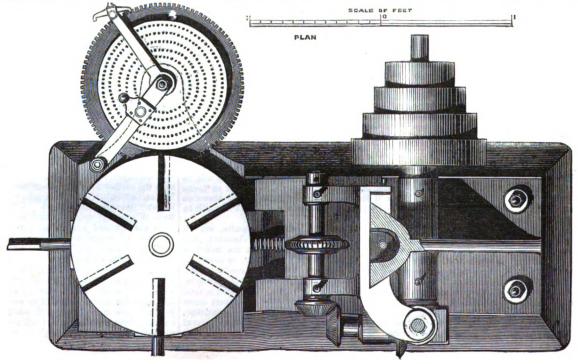

There must, however, be a limit to the size of the conductor, and between circuits of greatly differing lengths it is quite permissible to employ gauges of wire. No. 8 B. W. G. is different ample for a circuit of two hundred miles, but it unnecessarily large for one of two or three miles. A very considerable number of circuits do not exceed this length—for instance, those employed in train signalling—and for them a wire of No. 11 gauge is ample. Upon the other hand, for long through circuits of four or five hundred miles, it is desirable to increase the area of the conductor to about No. 4 gauge. In India, for local reasons, No. 1 is frequently employed. The greater cost of homogeneous iron wire renders it undesirable to be employed for ordinary lines of telegraph, neither is its superior strength necessary except for very extended spans. over-house telegraphs, where the spans are frequently from two to three hundred yards in length, and where the result of a breakage is serious, it is usual to employ a stranded iron wire. There are both advantages and disadvantages in the employment of a strand over a solid conductor. The strand is, perhaps slightly stronger, weight for weight, than the solid wire, 18 gauge wires weighing 7.32 lb. per 100 yards, breaking strain 600 lb.; a No. 13 solid wire weighing 7.05 lb., breaking strain 568 lb. larger surface exposed to the atmosphere is an objection in the strand, but its greater pliancy makes it safer to handle in passing it streets and over the roofs of houses. The size usually employed now is three strands of No. 18 Seven No. 20 gauge was formerly used, but the surface for oxidisation is too considerable.

With respect to insulators, their form should be such as-without greatly increasing their size shall present the longest straight line of resisting medium between their support and the wire resting upon them. The "invert," either single or double, meets this requirement. In addition to the prolonged surface of resisting medium, that part underneath the bell will be less su the be to the deposit of moisture than that which exposed. Here there will often be a zone or belt of dry surface when the remainder is wet. Of course this form is no protection against fog, which, it is well known, will find its way inside the neck of a bottle, but in rain the under side will be dry. The introduction of a metal cap over the earthenware was at one time presumed to be an advantage in lieu of the insulating invert because the heat which radiated invert because the heat which radiated from it quickly dried up the damp deposited upon the opposed surface of the earthenware; the loss of insulating surface was, however, a more serious disadvantage than any gain resulting from its adoption.

Every form of invert has, however, its dis-advantages, for since it is impossible entirely to exclude moisture, even from the under surface, and as, whilst moist, dust will be certain to settle, so whilst the first shower will wash all exposed surfaces clean, the under part will retain the dirt until cleaned by hand. The glaze upon the surface

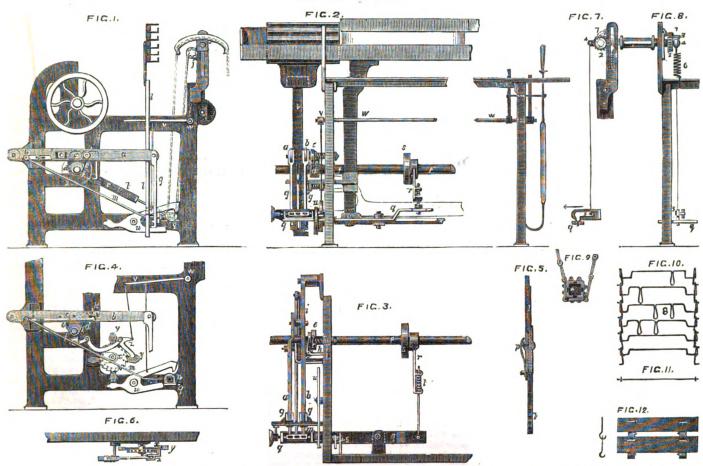

AUSTRIAN TOOTH-CUTTING MACHINE.

#### IMPROVEMENTS IN LOOMS.

BY MR. W. SHAW.

is of advantage, as it prevents the water forming a continuous film, allowing it to settle into un-connected drops. Glass is not a desirable material, because it more readily attracts moisture to its

surface than porcelain.

The chief causes of fracture in insulators are, stones thrown at them through mischief—an annoyance they are particularly subject to in the colliery districts—and the unequal expansion between the iron and the insulator in hot weather. To prevent the former, iron caps are frequently employed as a protection at an increased expense and with doubtful success. The latter being more general, is a more serious matter, and it becomes necessary greatly to increase the strength of the insulator in that part into which the iron is cemented, or to introduce a yielding material between the iron and the insulator, a plan adopted in 1855 by the author, who dispensed altogether with a permanent lute, and introduced vulcanised rubber tube. This plan has stood the test of fourteen years with perfect success. Ebonite has been largely employed as an insulator. In itself, ebonite—which may be considered as india-rubber deprived of a large proportion of its hydrogen by the action of sulphur at a certain temperature is probably the highest resisting medium in exist-ence; but exposure to the sun's light causes the surface to oxidise, and in this condition it becomes porous, and permits the superficial absorption of moisture.

The wooden supports upon which the wires are suspended form a very important item in a line of land telegraph. Originally all telegraph poles were of foreign timber, cut out of the solid balk. In appearance they were unquestionably superior to the rough larch poles so generally adopted now, but their cost was considerably higher, and their

durability not proportionate.

The extreme difference in the durability timber, placed in the ground, has attracted the attention of engineers for a lengthened period; but the telegraph engineer has to deal with the question so largely, and it forms so important an tem in his maintenance account, that the matter

has had very careful consideration at its hands.

The soil has doubtless much to do with the durability of timber, but the condition of the wood when set has much more to do with it. The buttend of an English larch pole of forty years' growth, felled during the winter, and having at least one years' seasoning upon it, will form a good and durable support. In selecting the poles it is best to choose those whose section shows the annulars to be close grown, with a fair proportion of "heart." Injections of creosote or sulphate of copper in solution may be advantageous, but if the sap be thoroughly expelled before the surface is painted or tarred, the timber will last very well. Constant attention is needed, however, to the ground line, a foot above and a foot below. At least every alternate summer the ground should be cleared out for a foot in depth round the pole, and the timber allowed to dry. When dry, a plentiful coat of gas-tar should be applied, and the soil filled in: the expense of this most necessary precaution will not exceed a few pence, whilst the advantage gained is very great.

It is necessary to test the interior of the timber occasionally by inserting a strong knife-blade, for it frequently happens that a fair exterior covers a mass of interior decay, the result of having allowed the sap to remain in the pores. Before the timber is placed in the ground it is advisable to char that part which will become the ground line, and to apply to it whilst hot—provided the sap has been entirely expelled—a mixture of one part of Stockholm tar, and four parts of gas-tar boiled with quicklime, to expel the water and ammonia.

The ordinary life of a telegraph pole may be taken as fourteen years, but the author has seen poles which have stood for twenty-four years in by no means the last stage of consumption, and he has seen others nearly decayed through, which have not been in the ground six years. He believes the cause of this remarkable difference is due solely to having disregarded in the latter case the principles just alluded to, either wholly or in

(To be continued.)

#### AUSTRIAN TOOTH-CUTTING MACHINE.

THE annexed engraving represents a very simple form of tooth-cutting machine of Austrian production, and which in the main resembles a well-known Leeds instrument for the same purpose. The mode of fixing the wheel on the double travelling

table, and pressing it by the hand-screw up to the revolving cutter, which descends through its cut automatically, is shown in the elevation, as well as the way in which the table can be tilted for beve work. On the plan is shown the method of advancing the wheel in which the teeth are being cut as each tooth is finished, by means of a wheel gearing into one on the spindle carrying the work, and provided with a brass dial with a number of concentric rings of studs. Each ring is differently spaced, and the lever arm carries a catch, which can be shifted to take on any of the rings, catching and moving forward by one or more pins as desired.

#### IMPROVEMENTS IN LOOMS.

MR. WRIGHT SHAW, of Clayton, Lancaster M has patented some improvements which relate to check looms, in which drop boxes are employed. These improvements consist, first, in the use of double-acting levers mounted on the loom frame, and reciprocating in opposite direcloom frame, and reciprocating in opposite direc-tions, which act in combination with a bowl mounted on a fixed stud on one of the levers, and which is caused to slide laterally, by a lever motion governed by the pattern chain, so as to bring the bowl in contact with one of two tappets of different diameters which actuate the same, thereby giving movement to the double-acting levers and bars suspended therefrom, which are provided at their lower extremities with notches or teeth. A second part of the invention consists in an improved construction and arrangement of the box rod, the upper part of which is attached to the boxes as usual, but the lower part is provided with a series of teeth or notches corresponding with the teeth or notches on the ends of the afore

said suspended bars.

A third part of the invention consists in an improved method of actuating the chain by the interposition of a spring between the lever carrying the barrel or cylinder and the tappet giving motion thereto. Another part of the improvements con-sists in an arrangement of apparatus for varying or retaining the number of picks from the same card, thus reducing considerably the number of links in the chain.

A fifth part of the invention relates to a novel arrangement of apparatus whereby pattern chains

varying in length may be actuated without causing any slackness, and consists in attaching to the taking-up barrel a ratchet wheel actuated by a attached to a lever having an adjustable weight. A sixth part consists in the use of shuttle boxes such as are used for plain weaving instead of the drop boxes when required. Seventhly and lastly, the invention relates to an improved form and construction of chain, and consists in the use of elastic wire or plate links of peculiar shape, which by slightly contracting or bending, they may be speedily coupled, their own elasticity retainthem in position and connection.

Such being the nature of Mr. Shaw's invention, we will now proceed to describe in detail the manner in which the same is carried into practical effect. In our engraving, fig. 1 is a side elevation of so much of a check loom as is necessary to illustrate the invention, and fig. 2 is a front view of the same; fig. 3 is a plan view of the improved apparatus. a b are the double-acting levers, to the latter of which is attached a stud carrying a bowl c capable of sliding laterally thereon, so that it may be brought into contact with either of the cams d e of different diameters fixed on the cam shaft f. The extremities of the levers a and b have bars g suspended therefrom, and provided with notches or teeth at their lower ends. h is the finger which moves the bowl in one direction when acted on by the sliding of the lever i which actuates the levers a and b, the bowl being returned to its original position when released by means of a spiral spring (as shown more clearly in fig. 4); & is the locking bar or pointer attached to the loom frame; Lis the drop box rod, the lower end of which is provided with a series of teeth corresponding with the teeth or notches on the lower extremities of the suspended bars q. When either of these suspended bars is brought into gear with the teeth or notches on the drop box rod, it imparts its rising or falling motion to the latter.

The suspended bars are brought alternately into contact with the drop box rod by means of needles m acted on by the pattern chain which passes round the cylinder n. o (see fig. 2) is the spring retaining bolt. The box rod l, as shown detached and partly in section at fig. 5, is constructed of two parts or bars which are capable of sliding one within the other, but are locked in their normal position by means of a V-shaped tooth p pressed upon by a spring so long as the drop boxes are working properly, but as soon as any unusual strain is caused, the spring and tooth give way and allow the bars to slide on each other, and thus breakage is prevented. The cylinder n is carried by a lever q connected by a root or link to a bowl working in a growy d cam or tappet con the shelf of working in a groov d cam or tappet s on the shaft f. This connecting rod or link r is made in two pieces, and is sufficiently rigid to actuate the cylinder, but is provided with a spring t which allows it to yield when required. The turning and stopping motion of the cylinder is effected by means of the horseshoe formed catch  $\nu$ , which is let fell and raised by means of a lever v on the catch rod w. The vibration of the lever q causes the upper limb of the horseshoe catch u to turn the pattern card cylinder n one-fourth a revolution at each movement, but should the loom be stopped at any time, either from the breaking of the weft thread or otherwise, the catch rod lever v raises the upper limb of the horseshoo catch u out of reach of the barrel pinion and places its lower limb in front of the lever q, and thus effectually stops the movement of the pattern cylinder.

#### COATING IRON AND STEEL WITH GOLD, SILVER, &c.

TN coating the baser metals with an adhering covering of silver, gold, or copper, the main difficulty is in purifying the surface of the metal to be coated; for unless the article to be coated is chemically clean no adhering coating can be deposited upon it. To overcome this difficulty is the object of a patent which has recently been taken out by Mr. J. B. Thompson, of Horton, near Slough. The purification, in the case of steel, iron, and cast iron, is effected by Mr. Thompson by means of nascent hydrogen in an alkaline solution. For obtaining this hydrogen in the nascent state, he uses a solution of hydrated oxide of sodium (of from 2lb. to 4lb. to the gallon of water). To this solution is added a small quantity of any of the compound cyanide salts which will not decompose readily under the action of a Daniell's battery of three cells; this will improve the solution, but it is not absolutely necessary. This solution is put into

a vat of iron to which the positive pole of a battery is attached. The articles being first made as clean as possible, they are passed in the vat and with the negative pole of the battery, the action of which must be such that a consider able current of hydrogen is evolved. Care should be taken to keep the solution up to the proper strength. The solution should be kept at a heat of from 120deg. to 150deg. Fah., and to prevent (what has been called) polarization of the articles by any excess of gas which may be evolved, which causes them to become black, and prevents their being thoroughly cleansed, the second part of the invention is necessary. When the articles have been in this vat from one to four hours, according to circumstances, they are transferred to the silvering, gilding, or coppering vat, and coated in the usual

The second part of Mr. Thompson's invention relates to the furnace and vat in which the cleansing solution is worked. The vat is an oblong iron vessel to which is connected a furnace and boiler The boiler is an upright one of the same height as the vat, and on the same level, made to hold two or three gallons, and connected with the vat near the bottom by means of a pipe of suitable bore, and also by another pipe near the top of the same bore. These pipes are of such a length that the vat is about 2ft. from the furnace. The action of the vat and boiler is this,—that when the solution is heated in the boiler it commences to circulate in the vat, a current flowing from the vat into the boiler at the bottom and from the boiler into the vat at the top as long as the heat is applied.

The third part of the invention relates to the burning in of the silver, gold, or copper into the iron or steel. This is performed by means of an apparatus of the following construction :- In the centre of a furnace is placed a melting pot of a size suitable to the work to be done. The bottom of this melting pot rests on the bottom of the furnace, and the fire is made round it so that the heat may be equal, or nearly so, in all its parts.
Within this melting pot is kept melted lead or an alloy of lead of a heat suitable for tempering steel. into which the articles are plunged and then quenched in water. The burning in of the silver may be performed by means of the flame of a blowother suitable flame, but the furnace is preferable for that purpose.

#### COMPENSATION FOR INVENTIONS.

WE have received the following memorandum from the War Office, which will doubtless interest most of our readers: to many it will prove of importance :- "In consequence of the numerous claims for compensation for loss of time, and for expenses incurred by private individuals in working out inventions of various kinds, as well as for rewards in consequence of such inventions, the Secretary of State considers it necessary to make known the following regulations:-

"1. Persons who desire to submit any invention for consideration should do so by letter addressed to the Under Secretary of State. The letter should describe the invention, and state whether the person who offers it for consideration desires to make any claim to remuneration in connection with it. In the absence of such a statement it will be assumed that no such remuneration is expected.

"2. Expenses incurred before the submission of an invention will not be considered to give a claim for repayment. No liability on behalf of the public will be recognized on account of loss of time or expenses incurred in connection with an invention after such submission, unless authority for such expenses has been previously given by letter signed by one of the Under Secretarios of State: and the liability will be strictly confined to the limits of expenditure authorized in such letter.

- "3. All claims for reward will be examined by council to be held at the War Office, and if any reward be recommended by the council and approved by the Secretary of State, the sum will, with the concurrence of the Treasury, be included in the Estimates, together with the report of the council: but it will not be regarded as due or be paid to the claimant until after the vote is passed by the House of Commons.
- "4. No claim for reward will be held to be established unless the invention has been adopted into the service, or substantial benefit to the public has resulted from it.

"War Office,
"February 23."

" NORTHBROOK.

RE-ROLLING OLD RAILWAY IRON

HE worn-out rails on the Erie and Pennsylvania Railways are re-rolled for further use in the same form, and this process is performed according to the following instructions, which are embodied in the specifications of that company:

1st. The old rails shall be piled in piles, and every piece shall be the whole length of the pile,

and the pile so made shall be rolled into flats.

2nd. All rails classed as 64lb, to 67lb, shall be olled from a 9in. rail pile, said pile to be made as follows .

3rd. The said flats shall be put into a pile of proper size for a rail, each flat being of the full length of the pile, and of which flats, the bar forming top or head of the rail shall be of a new, good, tough, granular re-worked iron, such as will weld well; to be 14in. thick.

4th. The lavers forming the central part or stem of the rail shall be of puddled or re-worked iron, of a good quality, or of old rails (at the option of the manufacturer), rolled to a thickness of not over in., and of such width that the various layers will break joints, and what is known as a staggered pile formed.

5th. The base of the pile, from which the bottom or flange of the rail is made, shall be of good re-worked fibrous iron—the under layer of which shall be of full width and length of pile, not less than  $1\frac{\pi}{8}$  in, thick. The pile shall be well and carefully heated, so as to insure a good weld.

6th. The short pieces furnished by the railway company, and all short pieces cut off by the rolling mill, shall be piled by themselves, and rolled into a flat, which flat shall either be piled in the rail pile or used in making flanges of the rail. The railway company shall have the right, from time to time, to direct in what part of said pile said flats so made of the pieces shall be placed: not more than two such flats shall be in any one pile.

7th. The rails to be rolled to pattern furnished by railway company; to be 25ft. long; not over ten per cent. shall be of shorter lengths, but not ess than 18ft.; all rails to be undercut kin.; to be notched 21in. from each end, the notch to be 1in. deep and fin. long, or of such dimensions as the

railway superintendent may direct.
8th. It is mutually agreed, that the railway company shall not exact from the iron works rails classed as re-rolled, to be of better material in the central parts and base of the pile than can be produced from the old iron furnished by said railway.

9th. Rails and process of manufacture shall be subject to inspection by such persons as the super-intendent of the railway shall select and appoint for that purpose.

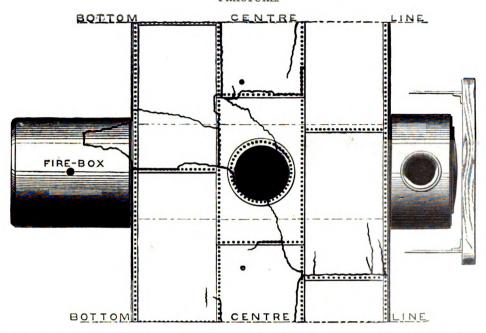

#### THE ROYAL NAVY IN 1869.

ON the 1st of February, 1869, the numerical strength of the British fleet-inclusive of ships atleat and building—was as follows:—Of armour-plated ships there were nine iron ships, third rates, afloat; seven of wood third rates, three of iron fourth rates, and seven building; two of wood fourth rates, affoat; one of iron fifth rate, two of wood sixth rates, and two sloops wood. The above are all screw steamers. There were two gunboats affoat double screw, one boat of iron, and one of iron and wood, and one ditto hydraulic. were two turret-ships afloat, iron, fourth rates, screw, and two building; there was one turretship of wood affoat, a fourth rate, with screw, and two others of iron, sixth rates, screw. One ram was building of iron, double screw. There were affoat three floating batteries of iron, screw, and and one of wood. This completes the lists of armour-plated vessels. Then there were fortyfour ships of the line, screw, afloat, and two building, but the building suspended. Thirty-two frigates, screw, were affoat: three ditto paddle: two block ships, screw; twenty-one corvettes, screw. and five building; thirty-six sloops, screw, were afloat, and two building; eight sloops, paddle, were afloat; ten small vessels, paddle; four despatch vessels, paddle; fifty-one gun vessels, screw and double screw, and three building; sixty-seven gunboats, screw, were afloat; ten tenders, tugs, &c., screw, and forty-one paddle; twelve troop and storeships, screw, and one ditto paddle; five transports for India reliefs, screw; four vachts, paddle, and one building. Thus there were 318 steam vessels afteat, and twenty-two building; and seventy-one paddle steam vessels affoat and one building; making a total of 389 steam vessels affeat and twenty-three building. There were besides the above, twenty other steam vessels, from which the machinery had been removed, affoat, making the total number of steam yessels 432.

### LOCOMOTIVE BOILER EXPLOSION.

PLAN, WITH THE PLATES IN THE CYLINDRICAL PORTION OF THE BOILER OPENED OUT FLAT, SHOWING THE LINES OF FRACTURE.

#### MANCHESTER BOILER ASSOCIATION.

THE last ordinary monthly meeting of the Executive Committee of this Association was held at the offices, 41, Corporation-street, Manchester, on Tuesday, January 26, 1869, William Fairbairn, Esq., C.E., F.R.S., LL.D., &c., President, in the chair, when Mr. L. E. Fletcher, chief engineer, presented his report, of which the following is an abstract:—During the past month 116 visits of inspection have been made, and 276 116 visits of inspection have been made, and 276 boilers examined, 142 externally, 7 internally, 3 in the flues, and 124 entirely, while, in addition, 5 have been tested by hydraulic pressure. In these boilers 98 defects have been discovered, 9 of them being dangerous. The following is a statement of defects, omissions, &c., met with in the boilers examined from January 1 to January 22, 1869, inclusive. Defects in boiler:—Furnaces out of inclusive. Defects in boiler:—Furnaces out of shape, 1 dangerous, 2 ordinary; fracture, 2 dangerous, 14 ordinary; blistered plates, 11 ordinary; corrosion, internal, 1 dangerous, 13 ordinary; corrosion, external, 2 dangerous, 18 ordinary; corrosion, external, 2 dangerous, 18 ordinary; grooving, internal, 2 dangerous, 15 ordinary; grooving, internal, 9 ordinary. Total, 6 dangerous, 67 ordinary. Defective fittings—Feed apparatus out of order, 1 ordinary; water gauges out of order, 6 ordinary; blow ont apparatus out of order, 3 ordinary; fusible plugs out of order, 7 ordinary; pressure gauges out of order, 4 ordinary. Total, 21 ordinary. Omissions—Boilers without glass water gauges, 3 dangerous; boilers without

pressure gauges, J ordinary. Total, 3 dangerous, 1 ordinary. Gross total, 9 dangerous, 89 ordinary. On the present occasion I have two explosions to report, by which four persons were killed and two others injured, while, as one of these occurred to the boiler of a locomotive engine, it may not be an inappropriate occasion to give the particulars of another explosion which occurred to a boiler of the same class a few months since, but which there has not hitherto been an opportunity of entering on. Not one of the explosions under consideration occurred to boilers enrolled with this Association. The following is a statement of explosions from January 1 to January 22, 1869, inclusive:—January 14, single-flue, or Cornish, internally

fired, 4 persons killed, 2 persons injured.

To deal fairly, therefore, with this catastrophe, and to learn from it all that it teaches, something else should be concluded than that it was due to "inattention on the part of the attendants." The boiler was allowed to work on by its proprietor with a dangerously disabled set of fittings, and thus it is thought he must at least share the responsibility of an explosion which scalded four men to death, and injured two others.

No. 2 explosion occurred at about two o'clock on the morning of Friday, January 22, to the boiler of a locomotive goods engine, by which the driver and fireman were severely shaken, though reported not to be much hurt, while fortunately beyond this, no case of personal injury resulted.

An officer of the Association was on the spot a few hours after the explosion occurred, but there has not yet been an opportunity of making a com-plete examination. This, however, it is fully expected, will be made in the course of a few days, so that the particulars may be reported to the members in due course; and in the meantime the details of the following explosion, which happened a few months since to a boiler of the same class, may not be uninteresting, since it is more than possible that they may give a clue to the cause of No. 2 explosion:—

The locomotive boiler explosion referred to occurred at about twenty minutes before seven o'clock on the morning of Tuesday, July 14, 1868, to the boiler of a locomotive engine employed in the goods traffic of one of our leading lines of railway. By it three persons were injured, but fortunately no one was killed. The engine had just left a station, at which it had stopped in the course of its journey, and entered an adjoining tunnel, with a train attached to it, consisting of a van and some fifty-seven waggons, when the explosion occurred, reducing the boiler to a wreck, severely scalding the engine driver, fireman, and leading guard, blowing down some platelayers at the other end of the tunnel, and shaking down some rockwork in a cemetery, under which the tunnel passed.

The engine was of the six-wheeled coupled class commonly employed for goods traffic, while the boiler was of the ordinary multitubular type, the barrel—which is the only part to which allusion need now be made—measuring 10ft. 9in. in length, 4ft. in diameter, and ½in. in thickness. There were three belts in the length of the barrel, each consisting of two plates, and so arranged that the longitudinal seams of rivets broke joint. The boiler was furnished with two open lever safety-valves, loaded to a pressure of 130lb. on the square inch by means of spring balances, fitted with suitable stop ferrules to prevent excessive pressure through the thumb screw being turned too far. It appears that the engine had been built in the year 1854 or 1855, while the tubes were taken out and the boiler thoroughly overhauled but three years before the explosion; in addition to which, slight repairs had been effected, and the engine turned out of the shop on June 30, 1868, after having been tested by hydraulic pressure up to 180lb. on the square inch, so that the boiler only ran about a fortnight after the last repairs before its explosion. When new it had been worked for some years with steam at a pressure of 140lb. per square inch, but latterly this had been reduced to 130lb.

The boiler rent in the barrel, nearly the whole of which was torn away from the fire box as well as the smoke box, and divided into three pieces, while the tubes were bulged out in a lateral direction both to the right and left, and the front tube plate torn away from the inner casing of the fire box. The

position and course of the rents, as well as the lay of the plates in the barrel of the boiler, will be better explained by the accompanying engraving than by any description.

On an examination being made of the frag-ments, it was found that the boiler had been attacked internally by corrosion, the bottom of the barrel being pitted from one end to the other and for a width of about 4ft., to a depth of onesixteenth of an inch generally, and one-eighth of an inch in some cases. Added to this, the plates were grooved at the bottom of the barrel at the an inch in some cases. edge of the overlap of the ring seams of rivets, one case to a depth of nearly 4in. Besides this, and which is of far more importance, there was a longitudinal furrow measuring 18in. or 20in. in length, and from three-sixteenths of an inch to a quarter of an inch in depth, at the edge of the overlap at a seam of rivets situated on the right hand side of the boiler, and in the belt of plates nearest the smoke box end. Where this furrow occurred, the plating was so arranged that the edge of the inner plate looked upwards and formed what is termed a shelf, which is generally thought objectionable on account of the facility it affords for the lodgement of corrosive impurities in the Through this longitudinal furrow the boiler rent, and there is little doubt that this rupture was the primary one from which the others sprung, and thus that the cause of the explosion was internal grooving or furrowing to which locomotive boilers are especially liable.

The subject of grooving or furrowing is a very important one with regard to locomotive boilers. It is, however, very simple, and too much mystery has been attached to it. This action takes place in stationary boilers as well as in locomotives, especially in those of the "Lancashire" type. The Association's inspectors are perfectly familiar with it, know at which part of the boilers to expect its effects, and regularly report upon them. It always takes place to a greater or less extent when an alternate hinging or buckling action occurs, combined with the use of a corrosive feed The parts of all boilers are in movement more or less from the local action of the fire and the internal pressure of the steam.

In the "Lancashire" boiler, grooving occurs in the majority of instances in the vicinity of the ends of the furnace tubes, in some cases attacking the end plates, in others the root of the angle iron, and in others the furnace tube itself. In these cases the grooving is at the crown of the tube, and assumes a transverse direction. The "Lancashire" boiler, if well made, is so abundantly strong in this direction that explosions do not occur to it from this cause, and little inconvenience is suffered beyond the occasional expense of repairs. There are but few boilers of the "Lancashire" type that are not affected more or less in this way, and were transverse grooving as dangerous as longitudinal,

explosions to this class of boiler would be much more frequent than they are.

In locomotive boilers the longitudinal grooves are caused by the constant changes of form which take place on the alternations of pressure, and thus induce the hinging or buckling action at the longitudinal seams of rivets already referred to, while it is possible in some cases that this may be promoted by the working of the engine. This distortion from internal pressure would not arise in the barrels of locomotive boilers if they were truly cylindrical; but the high pressure to which they are now worked has led to the adoption of thick plates, and it must be clear that the thicker the plate the greater the departure—with the ordinary overlap joint-from the true circle.

When making reference in the report for November, 1862, to an explosion of a locomotive boiler which occurred on the 8th of that month, and resulted, like the present one, from a longitudinal furrow at the edge of an overlap, I ventured to suggest the propriety of making the longitudinal joints with double butt strips, one being placed inside, and the other out, so that the true form of the circle might be maintained, the rivets placed in double shear, the line of strain always confined within the limits of the plates, and thus the parts maintained in equilibrio. Since then I have been informed by the locomotive superintendent of one of the main trunk lines of railway that he has adopted this plan, while he employs but one length of plate in the barrel of the boiler circumferentially, so that there is only one longitudinal joint in each belt, which he places above the tubes. so that it may not only be out of the water, and thus free from its corrosive action, but also in a part of the boiler more accessible to examination than when at the side or bottom of the barrel, as heretofore. This plan appears to be extremely simple, and all that is needed to prevent the occurrence of these longitudinal furrows from which so many locomotive boiler explosions arise, and therefore it was thought well to call attention to it on the present occasion, while it is trusted it will receive that general consideration which it appears to deserve.

ON XYLOGRAPHY, OR PRINTING AND GRAINING FROM THE NATURAL SURFACES OF WOOD.\*

BY MR. WILLIAM DEAN, SEN.

THE subject which it is my privilege to bring under the notice of your Society this evening. under the notice of your Society this evening, is a process for taking impressions from the grain of wood, and transferring those impressions on to other surfaces, and has been called "nature printing.

In showing my own patented process in different places, I have often heard it observed, "how very remarkable it is that this has never before been discovered," and indeed in that light I myself regard it, especially when I reflect on the fact that pieces of oak, such as I now hold in my hand, called by letter-press printers "reglet," have been in use by them for, I should say, at least a century, and probably for a much longer period, and that there never occurred to the thousands of masters and workmen, who, during that period, must have seen imprinted the veining of those reglets, the idea of turning the fact to practical account, and giving to it a commercial value. Yet such appears to be the case.

Before I enter on a detailed description of the process, I will glance at the range of the process and point out those branches of industry to which it is specially applicable. These are as follows:-For transferring impressions from wood to plain deal, or to painted surfaces, either flat or moulded. in buildings of all descriptions, where an accurate transcript of the more costly woods is desired, and for house and bedroom furniture generally; for japanned goods, made in metal or papier maché for enamelled parqueterie tiles, and for articles in earthenware, such as garden seats, oyster and flower tubs, spirit casks, flower-pots, tea-urn stands, &c.; for enamelled slate, for paperhangings, and for oil cloths.

Having thus briefly indicated the nature of the process, and the range of its application, I proceed to state the methods by which these results are Select a piece of wood of fine quality about 5ft. long, 12in. wide, and in thick; it is to use the technical phrase, cleaned up by the cabinet-maker on both sides, and is well sand papered down. By having both sides of the board

cleaned up, two patterns are tobtained from the same board. A chemical preparation is then applied to it, which has the effect of opening the pores of the wood, and, at the same time, of hardening the surface, and, when the board is thoroughly dry, it is ready for use, and is, in fact, a wood-plate, "not graven by art or man's device," but by the Great Designer and Architect of the Universe, whose works, the most stupendous as well as the most minute, are all perfect. The material used for taking the impression is prepared in oil, and is specially adapted for the purposes of transferring. The paper, too, is manufactured for the purpose, is very thin but tough so that it can be successfully applied to any irregular or moulded surfaces, and it is sized to prevent the colour from becoming incorporated with the body of the paper. A small wood roller is used for spreading the colour on the board, and a large, broad, flexible palette knife is used for taking the superfluous colour off. That being done, the sized paper is placed on the board, and both are passed through a small machine having turned-iron cylinders, the upper one being covered with double-milled flannel; the paper is then taken off the board, its printed surface is applied to the article to be decorated, the back of the impression is lightly rubbed with a piece of soft flannel, the paper is removed, and an exact fac-simile of the board from which the impression is taken is given. But that is not all, for a second and a third transfer are frequently obtained from the same piece of paper, and sometimes a fourth, a fifth, and a sixth. This is one of the remarkable features of the process, and, as you will not fail to perceive, must have a very marked influence on the rapidity of its application, and, consequently, on its cheapness. The thought may occur to the minds of some present, "but in taking off the impressions, does not the board get foul, and the pores of the wood clogged up?" The thought is a natural one. My answer is, that with the colour properly prepared, and adapted for its purpose, it does not, any more than does the plate of the copper and steel plate printer; but such a result would occur in both cases if the material used was not suitable for When a board has been used it is its purpose. treated as all other plates are, a cheap material is used for dissolving the printing colour, a handful of fine sawdust is then rubbed over it, which most effectually draws out of the pores of the wood the dissolved colour, and leaves the board clean, and ready for further use when required. Another question may arise in some minds, "but what about the durability of the boards?" The answer to that question may, at first sight, appear startling, but I am satisfied it is correct. The fact is that, under the same conditions, provided no accident happen to it, the board will be far more durable than either the copper or steel plate. I have arrived at that conclusion, not only from close observation, but from actual experience, for it is a fact that there are boards at Messrs. Thomas Simmons and Son's, Manchester, at Messrs. Minton and Co.'s, Stokeupon-Trent, and at the carriage works of the North Staffordsnire Railway Company, which have been in something like regular use for nearly three years, and my conviction is that they are in as good a working state at the present time as they were the day they were first used. Nay, more: I believe that some boards, with careful and constant use, improve rather than deteriorate.

There is one other point I will allude to before passing to the other important branch of the subject, and that is with respect to the variety of That question has sometimes met me in a very blunt form. I have been told that there would be either great sameness in the work, or I must take a timber yard with me. My answer to this is, not necessarily either the one or the other. For example, I take a board of the size already named (5st. long and 12in. wide), this I use on both sides, and from one such board I obtain 10ft. superficial variety of pattern, and in applying the impressions, it does not follow that they should all be applied precisely the same way; so that half-adozen boards of the size named would give 60ft. superficial of variety of pattern, and that variety would be trebled by judicious application, and would give ample variety for the largest room in a nobleman's mansion. But there is no necessity to limit the number, if greater variety is desired. But there is no necessity the boards being cheap enough, only costing about

The second division of the subject, and the one to which I shall now direct your attention, is the important one of quality and cost. In dealing with of the work you will be able to judge from the specimens it is my privilege to submit to you; and this, perhaps, may be a fitting time to make the statement, that I have had specimens at three industrial exhibitions; at two of them I was specially requested to meet the adjudicators of the prizes to explain the process to them, so as to enable them to form an opinion as to whether the patent possessed any commercial value, and in all the three cases. I was awarded either a prize or a certificate of merit.

I have taken considerable pains to bring my specimens and process under the notice of architects. both in London and in the provinces: in some cases an audience has been denied me, by some have been told plainly enough that they hate all imitations, but by others I have met with a very courteous, and, sometimes, a flattering reception. I will content myself with giving three illustrations in connection with architects; one of a large building firm in your own city, and two of practical grainers of eminence, one in London and the other in Manchester.

Mesers. Thomas Simmons and Son, builders and decorators, of Manchester, were among the first to adopt my process, and, after three years' experience of its practical value, have arranged with me for an exclusive licence for the city of Manchester and Salford. Shortly after they introduced it. they were employed to erect a mansion for a gentleman who had seen my specimens, and who wished to have the graining done by this process. The architect objected to it, but the proprietor persisted and carried the point. When the mansion was com-pleted, the architect, the proprietor, the builder, and the patentee met to look over the work. After the inspection. I took the architect to the entrancehall, to a point where the imitation was worked up to the solid oak, and where we had a good view of both; and, while looking at the work from that point, I asked the architect whether he thought was more than one person in a hundred who would be able to say where the solid ended and the imitation commenced. He replied very frankly that he thought there was not. I replied, that being so, I thought my process ought to have fair play, and it ought not summarily to be put out of court. He said he quite agreed with me, and that it had worked out much better than he thought it would You will readily imagine that I was perfectly fied with the result. I had fought the battle satisfied with the result. I had fought the battle of imitation, and won. The next illustration I shall cite took place in one of our largest provincial The architect has attained to considerable eminence of his profession, and the case afforded me some amusement. After a careful examination of my specimens, and listening to what I had to or my specimens, and astening to what I had to say in their favour, he called his chief assistant, and pointing to the specimens, asked him what he thought those were. He replied very promptly and emphatically, "I suppose sir, you call them shams." His reply was, "No, I shall not; these are not shams; they are a transcript from the wood itself and therefore must be both true and itself, and, therefore, must be both true and natural." Before we separated he thanked me for Before we separated, he thanked me for bringing the subject under his notice. The last professional illustration has reference to Mr. Robson, the corporation architect, of Liverpool. In that town new public offices have been erected, and about two years ago, the question arose as to what material and design should be adopted for decorating the dados in the corridors and staircases. After mutual deliberation, and having had several specimens put in position, Mr. Robson decided to apply the enamelled parqueterie tiles manufactured by Messrs. Minton and Company, as licensees under my patent. When the work was finished. Mr. Robson expressed his opinion that the parqueterie tiles had worked out very much to his satisfaction.

The building firm whose opinion of the quality of my specimens I shall now have the pleasure to quote, is among the most famous in your city; I allude to the builders of the new Foreign Offices, Messrs. George Smith and Co., of South-street. Judging from the solid oak work inside that building, I may safely say, that if any persons in the kingdom are competent judges of quality of work, they are; and I esteem the opinion expressed by Mr. Taylor, of that firm, of the utmost value to me. While Mr. Taylor was examining my specimens, Mr. Smith, jun., of that firm, came into his office. Mr. Taylor, after directing his attention to them, remarked, "This is what we are got to now; we cannot tell the solid from the imitation of it. I think I know as much about wainscoting as most men, and I defy any man to tell these specimens from solid wood." It is gratifying to me to be able tuem, instead of giving my own opinion, I shall from solid wood." It is gratifying to me to be able give that of others—persons of refinement and taste, and of large practical experience. Of the quality much as that class is the most sensitive on the

subject. The first is that of Mr. Mannooch, a name well known in London to the trade, and any opinion of his on the subject of graining, I am happy to know, is received with great respect. In showing my specimens to him, he remarked that he should like to see the process applied; and as he was erecting a house at St. John's wood, it was arranged that I should grain the drawing-room oak. The question of price per yard was left to him. the work was completed and varnished, he told me he should pay me 2s. per yard for it—which was double what I expected; that if he had known of it thirty years ago, he could have made a fortune out of it; and that I might with pleasure use him as my London referee. The other illustration is that of Mr. Bardsley, of Manchester—perhaps as good a grainer as is to be found out of London. I showed the process in Manchester to four gentlemen, of whom Mr. Bardsley was one. The article decorated was a piece of furniture. When I had finished, Mr. Bardsley said that I had done as much work in ten minutes as he could do in a day, to do it of the same quality. One of the other gentle-men replied, "Mr. Bardsley, you could not do it of men replied, "Mr. Bardsley, you could not do it of the same quality as that if you did take a day to do it. Mr. Bardsley smilingly said, "Well. perhaps I could not"; and added, "the simplicity of the process has taken me more by surprise than the quality of the work."

It would be easy to multiply illustrations, but I fear that I have already trespassed at too great length on your patience, and I must hasten on to deal with the question of cost, although you will not have failed to perceive that my last illustration touches both quality and cost.

(To be continued.)

## THE PROPOSED HURON AND ONTARIO SHIP CANAL.

THE promoters of this project state that they have A secured a subscription of 20,000,000 dollars from capitalists, in the United States, and have made a contract with an English contractor for a like amount, both dependent upon the condition that the Canadian Government shall donate to the company ten millions of acres of public land. This canal, its route, engineering features, and works throughout, may be briefly described as follows:—It will connect Lake Ontario (234ft. above the sea), with Lake Huron (574ft. above the sea), and have Lake Simcoe (704ft. above the sea), situated midway between them, for its summit level and feeder. The distance between its southern terminus, in Humber Bay, of Lake Ontario, and its northern terminus in Georgian Bay, of Lake Huron is 100 miles, of which 24 miles are deep water navigation through Lake Simcoe, and 16 miles slack water navigation in the northern extremity of the Nottawasaga river to its mouth in Georgian Bay; so that there will be only 60 miles of canal proper, of which 30 miles will be summit level, and only 30 miles interrupted by lockage. The canal will, therefore, be in two divisions—one south of Lake Simcoe 47 miles in length, and the other north of Lake Simcoe, and (including the Nottawasaga river), 29 miles in length. The southern division will commence in the Humber Bay, at a point about twenty-five chains west of the mouth of the Humber river, where it is proposed to make three lift locks in the solid ground, elevating the canal 45ft., and carrying it, by means of a stone aqueduct, over the Lake Shore-road, Great Western Railway, and side road. From the northern extremity of this aqueduct, the canal will be continued through the solid ground, to the village of Lambton, a distance of three miles, where it will join the river and receive its water supply. Following the valley of the Humber river for a bout three miles farther, to Weston, it will secured a subscription of 20,000,000 dollars from capitalists, in the United States, and have made of three miles, where it will join the river and receive its water supply. Following the valley of the Humber river for a bout three miles farther, to Weston, it will there intersect the Grand Trunk Railway, which is carried over the valley of the Humber by a viaduct about 60ft. above the water level. There the canal will be brought, by the necessary excavation in the bed of the stream, underneath the railway, at a level to afford 100ft clear headway for the passage of masts of vessels; its elevation to the natural level being effected, after passing beneath the viaduct, by three lift locks.

From Lambton, the canal will follow the valley of

three lift locks.

From Lambton, the canal will follow the valley of its eastern branch, to the From Lambton, the canal will follow the valley of the Humber river and its eastern branch, to the boundary line between the townships of Vaughan and King; in which distance of 21 miles, an ascent of 470ft. to the summit level will have been effected by means of thirty-one locks, of an average lift of 15ft. 2in. At this point, the largest feature of the work will be encountered. The highlands of the townships of King, there continue to rise until they attain a height of 186ft, above the level of Lake Simcoe (the summit) and then decline to that level townships of King, there continue to rise unit incy attain a height of 186ft, above the level of Lake Simcoe (the summit), and then decline to that level, within a distance of nine miles. The average depth of the necessary cut through this ridge is about 80ft, and the total excavation is computed at 36,000,000 cubic yards. It has been satisfactorily ascertained, by test-pits and boring, that the nucleus of this elevated ground consists of indurated clay and gravel, very similar to the exposed cliffs on Yonge-street, near York-mills, which appear to be a portion of the same g-ological formation; and that the upper or surface portion is clay, gravel, and sand of a friable nature. Notwithstanding the admitted formidable

surface portion is clay, gravel, and sand of a friable nature. Notwithstanding the admitted formidable nature and magnitude of this cutting, it is confidently believed that there is no insuperable obstacle in the way of its accomplishment, in a permanent and satisfactory manner. Through the entire length of this cutting there will be massive continuous piers, formed of boulders and concrete, and faced with close piling, secured to back stay piles, on both sides, to protect the foot of the slope.

This cut will bring the caual to its connection with the Holiand river, the course of which it will follow, through an extended flat, known as the Holland Marsh, for 14 miles, to its mouth on Lake Simcoe, Passing through Lake Simcoe, and out of it at Kemperfeldt Bay, another cut or excavation will be necessary, averaging for about 50ft, for five miles, to reach the Nottawasga river, the course of which will be followed to within threemiles of its mouth, in Nottawasga Bay, where, in order to save an extensive bend in the river, there will be a cut of about 40ft, deep, 1; mile through a sand hill with clay bottom. This last cut will bring it to its northern terminus. On the northern division of 29 miles, there is a descent of 130ft, effected by eleven locks, of which six will have an average fall of 15ft., and five of 8ft.

will have an average fall of loft, and five of sft.

There will be the railway and road crossings over
the Holland river near Bradford, where the unsatisfactory character of the ground calls for special
structures, to secure sufficient foundations for iron

The total lockage on the canal will be 600ft., and the number of locks forty-two. The width of the canal will be 100ft, at the water surface and 80ft, in the bottom, and its depth 13ft, except where these dimensions are necessarily exceeded by the width of the valleys and channels of the rivers through which it will pass, and through the deep excavation, where its width will be 80ft, both at the surface and bottom, with vertical piers on both sides. All the locks will be detached, to prevent the loss of time and consequent diminution of practical capacity for traffic, which would attend the grouping of locks together, in combination. The locks, sluices, and swing bridges will be operated by hydraulic power, except at the summit level, where steam power will be used. The works, throughout the line, will mainly consist of a stone aqueduct, to carry the canal over the Great Western Railway and two public roads; modification of the western viaduct to allow the passage of the canal under the Grand Trunk Railway; about 10,000,000 cubic yards dredging in the rivers; about 50,000,000 cubic yards excavation; 16 miles retaining piers on both sides of deep excavation; 60 miles of other slope protections; 42 locks complete, 250ft, by 35ft, with 13ft, on the sills; 25 miles iron hydraulic main, for operating lock gates, sluices, and swinging bridges; four special railway bridges; twenty-four iron swing bridges, for ordinary road crossings; entrance harbours at each terminus; dams, waste-weirs, offlets, culverts, and inlets; crib protections in Lake Simcoe; offices, workshops, storehouses, lock and bridge keepers' houses; 145 miles of towing path; about 140 miles permanent fencing. The time required for passing through the canal is computed at 42 hours thus: the number of locks forty-two. The width of the canal will be 100ft, at the water surface and 80ft, in permanent fencing. The time required for passing through the canal is computed at 42 hours thus:—

24 miles lake navigation, at 8 miles per hour 521 miles river and canal, long reaches, 31 miles per hour . 20 miles river and canal, short reaches, 2 miles 

Total

This rate of speed applies to steam propelled vessels. Sailing vessels, to attain to it, must be towed. Steam tugs will be specially provided for towage through the long reaches, and the hydraulic power for operating the lock gates, sluices, and swing bridges will be available for the short warping ponds. The estimated cost of all the works is 36,000,000 dollars, to which must be added the interest on expenditure during the construction, which, together, will absorb the authorized capital of 40,000,000 dollars.—"American Railway Times."

#### PHENOMENA OF LIGHT.

FEW would deny that the Parisians are a most ingenious race, but their ingeniuty is, perhaps, nowhere more conspicuously displayed than in devices by which they contrive to show their political devices by which they contrive to show their political opinions without unpleasant consequences to themselves. On Sunday last, says the "Pall Mall Gazette," one of the "conferences," now so much the fashion in Paris, was held at the Theatre de l'Ambigu-Comique on "the phenomena of light." a subject one would have thought about as unpolitical as could well have been chosen. Not a bit of it. as could well have been chosen. Not a bit of it.

The lecturer, in order to demonstrate certain theories, proceeded to enlarge some photographs of celebrated persons. Now, this being done by means of a strong magnesium light, all the theatre, except in the immediate neighbourhood of the operator, was in almost total darkness. The audience could be heard,

not seen. The portrait of the Emperor was received with a storm of hisses and cries of "A la porte!" "Vive la Republique!" "Il s'en ira bientot!" &c. "Vive la Republique!" "Il s'en ira biento!!" dc. That of the Empress met with a worse reception, if possible, than her husband's. On the other hand, the portrait of Maximilian was received with cheers and cries of "Qui l'a trahi?" Maximilian, as a bystander remarked, probably owed his popularity to the fact of his having been shot. The operator, like a prudent man, soon brought his experiments to an end, and when the gas was turned on the "agents" were very busy looking about, but, of course, every one looked intensely loyal. Can any one fancy a similar scene at one of Professor Tyndall's lectures?

#### AMERICAN ORDNANCE.

THE report of the Joint Committee on Ordnance, made in the Senate of the United States, by Mr. Howard, condemns both the Rodman system of gunmaking, adopted in the army, and the Dahlgren system, which is used in the navy. These systems, the report says, while partially successful with smooth-bores, have uniformly failed as rifles. Several of the Rodman guns have burst spontaneously while being finished in the foundries. The committee recommend that no more of them be purneously while being finished in the foundries. The committee recommend that no more of them be purchased, but that experiments be made to determine upon some more reliable system of fabrication. The failure to secure better guns than heretofore, the committee attribute to the fact, that officers have been gun inventors, and have secured by their influence the adoption of their inventions without regard to merit. The report is accompanied by a bill which places all experiments and the selection of arms for both army and navy in the hands of an of arms for both army and navy in the hands of an Ordnance Commission, to be composed of three army and two navy officers, and two civilians eminent for their attainments on the subject. The bill abolishes the Ordnance Department of the army by merging it in the artillery.

#### EXPLOSIVE COMPOUNDS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR—Observing a letter on the subject of explosive compounds in your impression of the 26th ultimo, I take the liberty of intruding upon your valuable space, in order, as far as my experience enables me, to correct some statements made therein. valuable space, in order, as far as my experience enables me, to correct some statements made therein. Mr. H. W. Reveley somewhat positively asserts that a large portion of black powder is always blown out of the gun unconsumed, perhaps to the amount of half the whole charge; that black grains may be seen to issue from the muzzle of a gun; and that it is advantageous for the whole of the charge of powder to be ignited instantaneously. With regard to the last statement, I cannot do better than quote his own words—"The sudden ignition of the whole charge is objected to by practical men, gunsmiths especially, who say, following an erroneous idea of Sir W. Armstrong's, that slow-burning powder is what is required for artillery, both large and small." It has been proved by actual experiment that slow-burning powders produced high velocities with rifled arms; thus, a charge of 20 grains of gun-cotton generates a larger volume of gas than 70 grains of gunpowder, but does not communicate so high a velocity to the bullet as the latter, simply on account of its excessive rapidity of combustion. Having had some experience in rifle shooting, I have never seen the black grains issue from the muzzle, although I should have been curious to do. 9 and should seen the black grains issue from the muzzle, although I should have been curious to do so, and should

I should have been curious to do so, and should imagine it would require superhuman eyesight to perceive them, even if they did issue.

If Mr. Reveley fancies that only one-half of the ordinary charge of powder acts propulsively on the bullet, he might easily fire some half charges and ascertain the initial velocity of the bullet. I cannot understand how, by the use of a quicker and, therefore, more dangerous powder, the weight of firearms can be reduced by one-third, especially as, in another part of the letter referred to, Mr. Reveley suggests increasing the thickness of metal in the breech of guns.

As one taking great interest in rifle shooting. I As one taking great interest in rile shooting, is should have been pleased to have seen the results of practical trials, proving the driving power of the powder referred to, as to volume and weight of charge, velocity and weight of projectile, and also some sort of proof as to its safety, by the firing of excessive charges.—I am, Sir, yours, &c. F. W. R.

### Meetings for the Week.

Tuss.—Royal Institution.—Rev. F. W. Farrar on "Comparative Philology," at 3 p.m.

The Institution of Civil Engineers.—Mr. Zerah Colburn, M. Inst. C.E., on "American Locomotives and Rolling Stock," at 8 p.m.

Wed.—Civil and Mechanical Engineers' Society.—Mr. B. Haughton, President, on "The Proposed Reconstruction of the Devenport and Torpoint Ferry and Landing Stages," at 8 p.m.

THURS.—Royal Institution.—Dr. H. Power on "The Eye," at 3 p.m.

THURS.—Royal Institution.—Dr. H. Power on "The Eye," at 3 p.m.

FRI.—Royal Institution.—Professor Abel on "Naval and Military Applications of Electricity," at 8 p.m.

Royal United Service Institution.—Mr. W. Cave

Thomas, Captain of the 19th Middlesex Rifle

Volunteers, on "Suggestions for Improving
Our System of Recruiting," at 3 p.m.

SAT.—Royal Institution.—Professor Odling on "Hydrogen," at 3 p.m.

### Habal, Military, and Gunnery Items.

THE navy estimates show a net decrease as compared with last year of £957,357.

DURING the past year, 1868, 3,547 vessels entered the port of Antwerp, and 3,504 sailed during the same period.

WE have to announce the death of Field Marshal Viscount Gough, the hero of Moodkee, Ferozeshah, and Sobraon, in his ninetieth year, which took place on Tuesday last.

THE Bavarian Minister of War has demanded from the Chamber a credit of 4,500,000 florins for new breech-loading rifles. In the course of his explanations he informed the house that the Dreyse system (Prussian needle-gun) had been rejected.

MAJOR CHARLES FREEMAN SANDHAM, late of the Royal Artillery, one of the few remaining survivors of the Waterloo officers, died on February 14, at his residence, Rowdell, in the county of Sussex, aged

THE precise number of lives lost in the catastrophe of the frigate "Radetzky," near Lissa, was 342, including the captain and all the officers, except one midshipman. Only twenty-three persons were saved, five of whom are seriously injured, and five others slightly.

THE Board of Trade are about to present to Captain F. Mahe, of the "Manille," of Havre, a pold watch and chain, in recognition of services rendered to the master and crew of the "Glengall," of Picton, Nova Scotia, who were rescued from the wreck of that vessel by the "Manille" in 1867.

THE Lords Commissioners of the Admiralty have issued a similar notice to that from the War Depart-ment which will be found on another page, to in-ventors, defining the grounds upon which alone any claim for pecuniary compensation will be recognized on account of plans and inventions adopted into the

An article, giving the history of fire-arms, in the French official journal, says that in 1428 the English employed fifteen breech-loaders against Orleans, and that some of the old Italian guns made of ribs of wood covered with hide are still to be seen in the arsenal of Genoa. These are the guns to which Machiavelli alludes.

On the evening of February 11 the steamer "Nellie Stevens" was destroyed by fire on the Red River, at Caddo Lake, and is a total loss. Sixty-three lives were lost, and but forty-three persons were saved. Among the lost were a large number of women and children. The cargo was chiefly hay, causing the fire to spread with great rapidity.

A NEW description of iron pavement has peen laid down in Chatham dockyard for experimental purposes. The principal merit of the new pavement over the old iron tramway formed of "Seeley's pigs" of iron ballast is that there is far less friction to be overcome in the heavily-laden vehicles passing over it, while about a quarter of the number of "pigs" at present in use will suffice for an equal length of paving.

THE "Bureau Veritas" of Paris, in its monthly ist of marine casualties, shows that in the month of January last the number of vessels totally lost was 269, of which 123 were English, 28 American, 18 French, 12 North German, 7 Dutch, 6 Norwegian,

and 36 of various other nationalities. The total number of disasters contrasts favourably with the records in previous years, the losses in January, 1866, having been 410, of 1867, 421, and in January, 1868, 264.

THE Naval Committee of the United States' House of Representatives reported on February 12 a bill to pay to Commodore Winslow and the officers bill to pay to Commodore Winslow and the omeers and crew of the war steamer "Kearsarge," the sum of 190,000 dollars as prize money, that sum being the estimated value of the "Alabama," which was destroyed by the "Kearsarge." An amendment was adopted providing that no part of the money should be paid to an assignee of any mariner, and the bill was passed.

WE are informed that the Moncrieff gun carriages. on the protected barbette system, which are now on the protected barbette system, which are now to be introduced into the service, will be constructed at the Royal Carriage Department, Royal Arsenal, Woolwich, under the superintendence of the inventor, who is to receive an annual salary as long as his services are required while the work is going ou, with a sum paid down for the invention. This fresh work will be gladly received by the workmen, numbers of whom are in receipt of little or no wages.

wages.

THE Parliamentary Navy Vote for the financial year 1869-70 will provide for 3,352 commissioned officers, 664 subordinate officers, 1,063 warrant officers, 28,401 petty officers and seamen, 7,000 boys on service or under instruction, 7,250 officers, men, and boys in the Coastguard Service afloat and on shore, 1,270 officers, men, and boys for troopships in the Indian service, and 14,000 officers and privates of Royal Marines, making a total of 63,000, without reckoning the 300 civilians in the Coastguard service. The vote for wages, &c., is £2,762,353. The vice. The vote for wages, &c., is £2,762,353. The vote of men and boys last session was for £66,770, with 350 civilians for Coastguard service.

On Tuesday and Wednesday last, a series of experiments were carried out at Shoeburyness; they included further trials of the Lancaster semi-oval rifled gun, Colonel Shaw's muzzle pivoting carriage, and a Frazer 9-inch gun against the new 8-inch armoured target, with simple wood backing. The Lancaster projectiles did not obtain rotation, insufficiency of twist in the rifle being stated as the consellation of the control of the state of the stat possible cause. Colonel Shaw's carriage endured the test well. The target constructed by Messrs. Cammell is a very fine one, and made better resist-ance than was anticipated. The 250-pounder shot and shell failed to perforate it.

THE "Patrie" tells the following story of a flag-It says that the chasseurs of the Guard had for duty to accompany the Emperor wherever he went. There were several squadrons of Mamelukes in the regiment, which was officered by men who had earned a place in history by their bravery. At Waterloo the chasseurs were commanded by General Lallemand, who escaped from that fatal field with the standard of the regiment. He sought refuge in America, and, when dying, he confided his treasure to King Joseph, who was also residing in the United States as Count Survilliers. King Joseph, when he returned to Europe, brought back the old flag, and left it in his will to such grandson who should embrace the career of arms and be worthy of the favour. This standard has just been handed to Prince Charles Napoleon Philippe Gregoire Bonaparte, Captain of Infantry, son of Prince Charles, and grandson of Lucien Bonaparte. It says that the chasseurs of the Guard had for duty Bonaparte.

## Miscellanen.

BAVARIA has just suppressed the monopoly of salt, with a view to the interest of agriculture.

THE heritors of the parish of Jedburgh have resolved, by a majority, to restore the Abbey Church at a cost of £4,200.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending February 27, was 4,226. Total number since the opening of the Museum, free daily (May 12, 1858), 1.511.462.

WE hear that in consequence of the anticipated drought at Mallingham, India, for the next four months, government have sanctioned four of Norton's American pumps being sunk in the bed of the river, running within 400 yards of the cantonment, and which is already at this early period quite dry.

A PROVIDENCE (Rhode Island) paper announces that a rope-walker will begin on June 1 the feat of propelling a velocipede 8,000 miles in thirty days. averaging 100 miles a day, for a wager of 5,000 dollars. During the trip he is to ride the velocipede 150 miles in twenty-four hours, and only one trial will be allowed.

THE number of visitors to the South Kensington Museum during the week ending February 27, 1869, was—on Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 12,784; Meyrick and other galleries, 2,127; on Wednesday, Thursday, and

Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,749; Meyrick and other galleries, 174; total—16.834. Average of corresponding week in former years, 10,881. Total from opening of Museum—8,193,125.

In consequence of the inundations of the salt mines of Wieliczka the Austrian government had charged a committee of seven of the principal engineers to institute an inquiry on the subject. These functionaries have now sent in a report to the effect that the irruption of water is not of a nature to destroy the mines or prevent their working; and that the pumps for emptying the pit are now nearly all set up.

MR. EDWIN CHADWICK, C.B., recently presided at a meeting of the Social Science Association, in the Adelphi, for the discussion of a paper by the Rev. Brooke Lambert, "On the Position of the National Schoolmaster." The great drawback pointed out by Mr. Lambert was that the national schoolmaster had no chance of rising, to remedy which he recommended that school inspectorships and the mestership of endowed schools should be which he recommended that school inspectorships and the mastership of endowed schools should be opened to him opened to him.

AT the monthly ballot of the Institution of Civil Engineers, on Tuesday last, the following candidates were balloted for and duly elected as Members: Messrs. W. J. Forrest, J. Johnson, H. N. Maynard, and E. R. Scott: as Associates, Messrs. C. Barnard, J. H. Blake, H. Chubb, A. D. Fox, R. A. Robertson, Major J. H. M. S. Stewart, R.E., Captain E. T. Thackeray, V.C., R.E., and Mr. F. Turner. It was announced that the following gentlemen had recently been admitted as Students of the Institution:—Messrs. J. G. Barton, H. M. Bell, H. W. Dallas, T. Inman, S. Moyle, and H. O. Smith. AT the monthly ballot of the Institution of Civil

S. Moyle, and H. O. Smith.

At the ordinary meeting of the Society of Engineers, held on the 1st inst., Mr. F. W. Bryant, President, in the chair, a paper was read on "Electric Telegraphy, irrespective of Telegraphic Apparatus." by Mr. E. G. Bartholomew. The following candidates for election were balloted for and duly elected as Members, viz:—Messrs. Wm. Martley, Locomotive Superintendent, London Chatham and Dover Railway, Longhedge, Wandsworth; John Baldwin, Engineer, Novarino-road, Dalston; John Blackbourne, resident engineer, Limehouse Basin Works; and, as Associate, Mr. James William Restler, New Water works. Hampton. works, Hampton.

AT the meeting of the Royal Horticultural Society At the meeting of the Royal Horticultural Society on Tuesday there was a rich display of orchids; the Duke of Edinburgh rose was the gem of the show, while on a smaller scale a group of different species of primula and a collection of spring flowers attracted much attention. Mr. James Bateman, F.R.S., presided, and the following candidates were elected fellows, viz:—N. B. E. Baillie, H. P. Baylis, Sir J. R. Blois, Bart., Clement C. Dormer, W. P. Elzee, Mrs. Elliott, Captain Baskervyle Glegg, Sydney Kennedy, Colonel A. R. Manson, James D. Purks, Frederick Payne, Henry George Quilter, St. Barbe Slayden, Jacob Walter, James Parker Woodhouse, &c.

PROFESSOR W. A. MILLER has announced the discovery of a means by which the red prominences which form so remarkable a feature of solar minences which form so remarkable a feature of solar eclipses may be seen at any time. The method consists of intercepting by means of coloured glasses all the components of solar light except those of which the prominences are composed. The chromosphere, as the surrounding stratum of hydrogen discovered by Mr. Norman Lockyer is called, being of the same composition, will also be thus visible. This discovery will enable astronomers easily to observe the disturbances in the prominences, and their connection with the spots and other solar phenomena.

The President of the United States has sent to the Senate for ratification the treaty he has concluded with the government of New Granada respecting the Darien Ship Canal. This treaty, it is understood, gives the exclusive right to construct the canal to American citizens, and its ratification is regarded as secure. The canal must be completed fifteen years after the ratification of the treaty, and the capital necessary for the undertaking is said to be already pledged. From Nicaragua it is announced that the Government of that State has concluded a treaty with M. Chevalier, the French senator, as the representative of a French company, giving them the right to construct a canal to connect the uceans, across Nicaragua. THE President of the United States has sent to across Nicaragua.

across Nicaragua.

At the general monthly meeting of the Boyal Institution of Great Britain, held Monday, March 1, 1869, Sir Henry Holland, Bart., president, in the chair, Peter Allen, M.D., Frederic Kett Barclay, Esq., Mrs. Bowie, Thomas Boycott, M.D., F.L.S., Henry Chester, Esq., Professor A. H. Church, M.A., Charles Cogswell, M.D., Mrs. Charles Crokat, Edward Dent, Esq., William Gardiner, Esq., Gilbert F. Girdwood, Esq., Walter Henty, Esq., Charles Latham, Esq., John Macdougall, Esq., Edward Moberly, jun., Esq., Robert Palmer, Esq., Rev. George C. Pearson, M.A., Alfred Rowlls Rowlls, Esq., Archibald Travers, Esq., Alfred Wills, Esq., were elected members of the Royal Institution, F. Leighton, Esq., was admitted a member of the Royal Leighton, Esq., was admitted a member of the Royal Institution.

UP to the close of 1850 the value of the Californian gold exported from San Francisco was 66,000,000dols. In the eighteen years which have since elapsed the value of the gold exported from the great Pacific

value of the gold exported from the great Pacific port has been as follows:—

dols.

dols.

dols.

dols.

dols.

1851, 45,989,000

1857, 48,976,692

1863, 46,071,920

1853, 45,955,000

1859, 47,640,462

1865, 44,46,172

1854, 52,045,633

1860, 42,325,816

1865, 44,46,172

1854, 52,045,633

1860, 42,325,816

1863, 44,365,668

1855, 45,161,731

1861, 40,676,788

1863, 36,338,996

The aggregate from 1848 to 1868 inclusive was thus no less than 897,968,267dols. It must not be assumed that all this was gold newly raised from the earth, as it included coin; still, there can be no doubt that a very large proportion was virgin gold.

doubt that a very large proportion was virgin gold. The yield of the precious metals in the United States, during 1868, is estimated at 66,500,000 dollars. California produced the largest amount, 20,000,000 dollars, and after it come Nevada, 18,000,000 dollars; Montana, 12,000,000 dollars; Idaho, 6,000,000 dollars; Oregon, 5,000,000 dollars; and Colorada, 4,000,000 dollars. Washington, New Mexico, and Arizona territories produced smaller amounts. The yield is regarded as stationary, with the prospect that the opening of the Pacific Railway, which runs through several of the gold and silver regions, will have a tendency to increase it. The influx of Chinamen, too, lessens the cost of labour on the Pacific coast. It is announced that much of the capital that was invested in American gold and silver mining enterprises during 1868 came from England.

An Indian journal gives the following as the

An Indian journal gives the following as the ntents of the stomach of a crocodile lately captured contents of the stomach of a crocodile lately captured near Agra:—About a dozen large bunches, pellets, of hair (probably human); 68 rounded pebbles, averaging in size from nearly 3in. to lin. in diameter, 1 large aukle bangle ring of mixed metal; 24 fragments, of various sizes, of vitreous armlet rings; 5 bronze finger rings; 1 small silver neck-charm; a small defaced silver coin, with a metal loop, for suspension, attached to it; one gold bead, about one-third of an inch square; 1 largish bead, of black stone veined with white; and thirty small red necklace beads. All these things (barring the stones) it is taken for granted must have been the ornaments of some woman (if not more than one) who had been of some woman (if not more than one) who had been devoured by this monster. The skeleton of the devoured by this monster. The skeleton of the crocodile was being prepared as a specimen for the Reddell Museum, Agra.

## Patents for Inbentions.

#### ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclu-sively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledg-ment:—

ment:—
BOILERS AND FURNACES—2479, 2484, 2497, 2517
BUILDINGS AND BUILDING MATERIALS—2481, 2518
CHEMISTRY AND PHOTOGRAPHY—2480, 2491
CULTIVATION OF THE SOIL, including agricultural implements and machines.—2526, 2536
ELECTRICAL APPARATUS—2492, 2496, 2505, 2523
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2472, 2475, 2477, 2515, 2522, 2524, 2527, 2535, 2537, 2538

2552 STEAM ENGINES-2485, 2488, 2490, 2499, 2512, 2513 WARFARE-2468, 2478, 2483, 2534

2463 A. M. CLARK, Chancery-lane, Scisors. Dated August 6, 1868.

This consists in jointing the tangs or legs of scissors, so that the bows may be folded against the blades, to enable them being carried in the pocket without danger.—Patent completed.

completed.

2464 W. and E. M. HANN, Durham. Safety lamps. Dated August 6, 1868.

The object of this is to protect the flame of the lamp from pressures of wind, that only sufficient air be admitted to supply the combustion of the flame. The improvements relate chiefly to the class of lamp known as the Stephenson lamp, in which a glass chimney is employed, within an outer casing of wire gauze. In order to prevent the passage of any current of air or gas between the gauze and lower end of the glass chimney, the patentees fit the bottom of the glass to the upper surface of a ring, which has projecting from its upper surface a cylindrical flange, which

fits within, or it might be to the outside of the glass, such glass chimney being fitted both to the flat aurface of the ring and to the flange by grinding. The cylindrical gauze casing, which surrounds the glass, is continued down below the glass, and through this lower part of the gauze, air is admitted to the lamp; the outer circumference of the ring which carries the glass fits accurately to the interior of the gauze casing above the point of inlet of air; whilst at the point, the exterior of the gauze is embraced by the lower framework of the lamp, the gauze being thus held between two metal surfaces fitting closely against it.—Patent completed.

2465 W. B. LANE Chancervalane. Felled fabric. Dated

2465 W. B. LAKE, Chancery-lane. Felted fabric. Dated August 5, 1868.

This relates to imparting a stiffness and body to felts. by incorporating hair, preferably horsehair, in the body thereof.—Patent completed.

2466 A. V. NEWTON, Chancery-lane. Boots and shoes ated August 6, 1868.

2466 A. V. NEWTON, Chancery-lane. Boots and shows Dated August 6, 1868.

A base or core extending from toe to heel is made of thin sheet iron, which is stamped out to the required size and shape, but with spurs all round, except at that part which forms the waist. These spurs, when bent up, as will be presently explained, will serve to form a kind of wall or square edge to the sole and heel, and determine the thickness of filling they shall receive. The base plate is protected by a canvas covering secured thereto, by japan or varnish, a thick prepared canvas being applied to the under side of the core, or that part of it which is known as the tread. Over this canvas is applied another coating of prepared canvas, and these fabrics are secured to the metal, core by means of burrs, or sharp teeth punched out of the metal, and projecting vertically from its under face.—Patent completed.

2467 W. M. MOORE. Dublin. Paper holders. Dated

of the metal, and projecting vertically from its under lace.—Patent completed.

2467 W. M. MOORE, Dublin. Paper holders. Dated August 6, 1868.

Two boards of wood are connected by a flexible hinged joint. The two boards are held firmly but elastically together, by being nipped between a pair of laths or strips of wood, or other suitable stout material, such laths being held together by india-rubber, or other suitable springs, applled to their extremities; a ridge or projection is formed near one edge of both the boards, to prevent the laths from being accidentally disengaged from or stripped entirely off the boards. When these laths are brought into a diagonal position, so as to pass across the joints, in one of the boards, the entire surface of that board will be maintained flat against the documents, effectually covering or protecting them, and securing them in their places, but by moving the laths along the board, so as to leave one or other of the joints free, then the corresponding parts of the jointed board may be folded or turned down, so as to expose any desired portion of the document, or (if the document is provided with a wide margin) to expose the whole of the writing on one side, the margin alone being concealed and held between the boards.—Patent completed.

2468 T. W. STAPLETON, Regent-street. Breech-loaders.

2468 T. W. STAPLETON, Regent-street. Breech-loaders. Dated August 7, 1868.
The striking bolt, together with the hammer, which actuates it, are enclosed inside the lock of the gun, thereby presenting no opening for the admission of dust or damp, and preventing the hammer from coming in contact with any external object. The striking and locking bolt, instead of being hinged to the head of the hammer, as is the case in other rifles; of this description, is imounted, independently of the hammer, the head of which enters a recess or notch at the end of the bolt. The bolt is thus capable of being shot backwards and forwards in the top of the lock. The arm is cocked from below, by means of a lever, which forms the trigger guard.—Patent abandoned.

2469 C. W. CURTIS and A. FIDDES, Bristol. Safes. Dated August 7, 1868.

The frame is constructed of angle iron or metal, and provision is made for the reception of drill-proof rollers, which are to cover the whole surface of the safe. The rollers are inserted in grooved iron plates irregularly.—Patent completed.

2470 E. W. MADDICK, Holloway. Forks and spoons. Dated August 7, 1868.

The patentee fits to the stem of the fork or spoon asilde, so that they can be used as one article, or they can be disconnected and be used separately.—Patent abandoned.

2471 B. HUNT, Lincoln's Inn. India-rubber fabrics. Dated

2471 B. Hunt, Lincoln's Inn. India-rubber fabrics. Dated August 7, 1868.

Sheets of india-rubber are pierced or perforated all over with minute holes, the size, number, and distance apart being varied, according to circumstances, but they must be of sufficient size to allow of air and gases passing through, and to be plainly visible on holding the fabric up to the light; at the same time, they must be sufficiently minute to prevent the passage of water, excepting when pressure is applied.—Patent completed.

2472 J. WHITEHEAD, Manchester. Dandy rollers. Dated August 7, 1868.

August 1, 1808.

The body or framework of the roller is composed of pieces of wire soldered or brazed together in several parts, so as to form a strong skeleton frame, on which the wire gauze or laid work is placed.—Patent completed.

2473 N. SALAMON, Ludgate-hill. Seeing machines. Dated August 7, 1868.

This consists in fitting a curved lever to the back of the head of a sewing machine, to operate the pressure foot, and by which the pressure foot can be lifted clear of the work plate. The pressure foot enters a stop which presses on the spiral spring. A guide wire is employed to lay a braid in line with and under the needle.—Patent completed.

2474 H. BENJAMIN, Abbey-road, Washing machine, Dated

2474 H. BENJAMIN, ADDRY-TORU. WARRING THE AUGUST 7, 1868.

This consists of a hollow quadrangular star-shaped vessel, provided with a covered opening, for inserting or withdrawing the clothes. By this arrangement, the articles under operation (as the chamber revolves) are projected against the angular cavities, and thereby cleansed, independently of any intermediate stirrers or beaters hitherto in use.—Patent completed.

2475 J. LITCHFIELD, Nottingham. Lace machines. Dated

2475 J. LITCHFIELD, NOTHINGHAM.
August 7, 1868.

A twist lace machine of ordinary construction is employed, with two warp threads to each bobbin thread. The warp threads are carried in two warp bars, which have a movement given to them, so that when the jacks or stops do not operate to modify the action of the bars on the threads, the threads carried by one bar twist constantly, each with its own bobbin thread, and the threads

carried by the other bar traverse to and fro over three or other number of bobbins. In producing the pattern or finings, all the jacks or stops are kept out of action. In producing the ground net, the jacks or stops operate obth sets of warp threads; those threads which, as already mentioned, are by their warp bar carried only one gate or space, and are by the jack bar from time to time moved a second gate or space, so as to make a crossing to another bobbin thread—Patent abandoned.

a second gate or space, so as to make a crossing to another bobbin thread.—Patent abandoned.

2478 W. E. Newton, Chancery-lane. Regulating speed.
Dated August 7, 1868.

The piston rod of an engine is connected by a link or connecting rod to one end of a vibrating lever, mounted on what the inventors term the shaft of resistance, at a point above the point of connection of the piston rod with the vibrating lever. On the side of this lever is mounted a small bell crank lever, which is capable of rocking on its centre of motion within certain limits, that is, between two fixed stude, which circumseribe the action of one of the arms of the bell crank lever. This arm is connected by a rod to the mechanism to be actuated, or to the motive engine to be regulated, while its second arm is connected by a rod or link to the arm of another bell crank lever whose centre of motion is fixed, while that of the first bell crank lever is movable, being situated on the vibrating lever. The upper arm of the second lever is connected by a rod to the cut-off valve of the engine, which is worked thereby. Thus, in the event of any irregularity of motion in the mechanism, and which it may be desired to correct or compensate, then the rod which works the first bell crank will move it more or less accordingly, and will, through the second lever and gear, regulate the cut-off of the steam.—Patent completed.

2477 G. Leach, Leeds. Carding. Dated August 7, 1868.

through the second lever and gear, regulate the cut-off of the steam.—Patent completed.

2477 G. LEACH, Leeds. Carding. Dated August 7, 1868. This invention relates, first, to an improved fixing or bearing or stardard, for the small card rollers of engines, known as workers and strippers, whose office it is to take the fibres from and return them to the main cylinder. The object is to make the bearings easily adjustable, both vertically and laterally, and thus to ensure their proper and efficient action. The axle of each worker and stripper is carried in a pair of bracket bearings, which are formed with stems screwed at their lower end, and passed through ring flanges on the sides of the framing. The stems are made fast to the framing by clamping nuts. Each bracket stem is dropped through a socket piece, made fast to the framing by a clamping nut and steady pins. This socket piece is fitted at its opposite sides with set screws, by means of which the bracket stem may be adjusted so as to throw the worker or stripper, as the case may be, forward or backward, while, by the clamping nuts, their vertical adjustment is effected. The invention relates, second, to an improved method of taking up the silver as it comes off the doffer of the carding or scribbling engine. The silver, as it is stripped in the usual way from the doffer, is taken up by and wound upon a drum or cylinder of the bat forming machine.—Patent completed.

2478 W. E. Næwton, Chancery-lane. Firearms. Dated

upon a drum or cylinder of the bat forming machine.—Patent completed.

2478 W. E. NEWTON, Chancery-lane. Fivearms. Dated August 7, 1868.

This consists, first, in the combination of a tubular magazine for containing a series of charges, with a sliding barrel which is closed when drawn back in contact with the recoil shield to enclose a cartridge, and which is open to receive a cartridge when pushed forward from the recoil shield. Second, mechanism for elevating cartridges one by one from the magazine up to the line of the barrel in combination with the sliding barrel by which such mechanism is operated. Third, an arrangement of mechanism for cocking the hammer by the sliding forward of the barrel. Fourth, of a spring for drawing the barrel forward from the recoil shield, in combination with catches for locking the barrel when the rear breech is drawn back in contact with the recoil shield. Fifth, an arrangement of mechanism for holding the cartridge in line with the barrel while the barrel is being drawn back to enclose it and the lifter is being depressed. Sixth, a means for preventing the trigger from being drawn back to fire the charge unless the barrel is in the right position and locked. —Patent completed.

2479 J. Arnoll, Sheffield. Steam boilers. Dated

—Patent completed.

2479 J. Arnold, Sheffield. Steam boilers. Dated August 7, 1868.

This consists principally in inserting a hemispherical dish-shaped auxiliary water space in the firebox, and in connecting it to the top of the firebox by means of tubes, by rivets or otherwise, so that a free circulation of water is established between it and the water space above.—Patent abandoned.

2480 L. GARDNER, Neath. Annealing pots. Dated August 8, 1868.
This consists in the construction and employment of annealing pots and stands of a corrugated form.—Patent completed.

completed.

2481 J. Broadfoot, Glasgow. Water-closets. Dated August 8, 1868.

This apparatus comprises a main discharge valve of a spherical form, with a cylindrical way through it, and which is held in a spherically-shaped box made in two halves. The valve is made with a shell of gun metal, in which a tube of copper is soldered, to form the way through it. The shell is cast with spindles or journals on it, and apertures in the box through which these pass are kept tight by stuffing boxes. One of the spindles has fixed on it a curved slotted crank, arm, or lever, acted on by a pin with a roller fixed to a lever, that has the usual hand rod attached.—Patent completed.

2489 B. Hunt Lincoln's Inn. Blind furniture. Dated

2482 B. HUNT, Lincoln's Inn. Blind furniture. Dated

August 8, 1868.

This apparatus consists principally of a grooved pulley fixed on one end of the roller, and having a hollow projecting centre or box, in which is placed a spiral or coiled spring. The inner end of this coiled spring is attached to the centre of the pulley, and the outer end thereof is attached to the plate or bracket which carries the fixed pin or pivot on which the pulley is mounted and turns. Two small grooved pulleys, placed a small distance apart, are attached to the bracket below the roller pulley, and serve to guide and facilitate the working of the endless cord.—Patent abandoned.

2483 J.Kirk, Woolwich. Fortifications. Dated August 8, 1868.
The shield is divided into a convenient number of cells or chambers, so constructed and arranged that they can be readily filled or charged with water, in order to offer increased resistance to projectiles.—Patent completed.

2484 J. STANDEN, Borough. Multitubular boilers. Dated August 8. 1868.

The object of this invention is to counterbalance the pressure on the tube plates of multitubular boilers. The patentee forms the centre part of the top of the boiler (supposing it to be an upright boiler) with a head or dome of a cylindrical shape. The dome is not fixed to the flat top, but passes through a large hole or opening formed therein, and is so formed as to receive packing which surrounds and encircles the dome, and allows it to have free play through the fixed top as expansion and contraction goes on.—Patent abandoned.

2485 A. V. NEWTON, Chancery-lane. Steam engine governor. Dated August 8, 1868.

This apparatus consists of a receiver fitted with a movable cover or elastic diaphragm, to which is connected a crutch, jointed to a throttle valve lever. The receiver is also provided with an outlet, having an adjustable valve applied to it for regulating the escape of fluid that is forced into the receiver by a supply pump worked by the engine to be regulated. The supply pump is double acting, and its object is to supply fluid (through branch pipes fitted with floating valves) to the reservoir, in such quantity as to keep the cover or diaphragm, and thereby the throttle valve of the engine at a position for controlling the speed of the engine, a regulated escape for the fluid from the receiver being at the same time kept open. By this arrangement, should the speed of the engine exceed or fell short of the prescribed limit, the fluid will be forced into the receiver faster in the one case and slower in the other than it escapes, by which means the cover of the receiver is caused to operate upon the throttle valve, and open or close this valve more or less.—Patent abandoned.

2486 W. E. Newton, Chancery-lane. Screws and screw direers. Dated August 8, 1868.

abandoned.

2486 W. E. NEWTON, Chancery-lane. Screws and screw drivers. Dated August 8, 1868.

This consists in providing the screw head with two or more triangular notches extending through it, and slightly dovetailed, whereby it is adapted to be grasped and held firmly by two or more gripping jaws inserted in sockets in the end of a stock or tool. The ends of the jaws which thus operate are bevelled so as to form cutters which roam away the wood, and prepare a countersink under the head of the screw, as the heaf approaches the surface of the wood with which, when the screw is fully inserted, its head lies flush.—Patent completed.

2487 D. NICKOLS, Manchester. Taps. Dated August 8,

2437 D. NICKOLS, Manchester. 20ps. Dated August 8, 1868.
This consists in arranging and combining with the cone plug mechanism by which it can only be slowly rotated, namely, a worm wheel upon the axis of the plug gearing into a worm, on a short shaft formed with a handle.—Patent abandoned.

2488 H. Dubs, Glasgow. Steam crane. Dated August 8.

1888.

This consists in the construction and use of a new or improved "crane locomotive," or a locomotive steam engine and self-acting or steam jib crane combined. The patentee claims, first, the construction and arrangement of the parts generally of a steam crane and locomotive engine combined. Second, the construction and arrangement of the parts generally for actuating the supply steam valve and link motion of the engines of the crane through its axial pillar in combined steam crane and locomotive engines.—Patent completed.

2489 E. William S. Staines Resignate extent.

engines.—Patent completed.

2489 F. Walton, Staines. Resinous cement. Dated August 8, 1868.

The patentee puts into an open pan, heated by high pressure steam or fire, 160lb. of kourie or New Zealand gum; when this is fused, he adds 80lb. of castor oil; the heat is continued with constant stirring until the two substances become intimately combined, which may be known by the liquidity of the combination. This material is suitable for cementing substances together, such as wood or stone, or caulking seams of vessels or tanks.—Patent completed.

2490 J. HIRD, Bristol. Motive power. Dated August 8

1868. The patentee connects the flywheel of the first motor to a shaft containing a pulley keyed thereto, from which a driving band extends to a second shaft carrying a pulley and flywheel, the diameter of which, and the consequent weight, are much greater than the first, and from this second series he again operates a third series, the flywheel of which is proportionally increased in size and weight.—Patent abandoned.

2491 T. KENYON, Manchester. Sulphuric acid. Dated August 10, 1868.

The patentee takes nitrous and sulphurous gases and forces them through a solution of weak sulphuric acid; as the gases rise therefrom, they are met by a spray of weak sulphuric acid combined with air and high pressure steam.—Patent abandoned.

steam.—Fatent abandoned.

2492 F. LE ROY, Commercial-road. Non-conducting compound. Dated August 10, 1868.

This composition is intended to be used as a substitute for mortar and cement in building or stopping up boilers. The patentee takes lewt. of brick clay, 70lb. of powdered charcoal, 28lb. of sawdust, 28lb. of fuel sweepings, 8lb. of cow hair, 8lb. of cocoa nut fibre, 2lb. of flour, yeast, or other formentable substance, 8lb. of the residues from the conversion of starch into sugar, 80lb. of water, and 36lb. of cotton foot oil. The above ingredients are placed in a vessel containing a stirring apparatus, which is set in motion, and as soon as the substances are well mixed and combined into a paste or mortar, it is changed into a fermenting vat and submitted to such a heat as to cause the fermentation, by which a homogeneous self-adhesive substance is formed.—Patent completed.

2493 T. CORFIELD, Falmouth. Paper bags. Dated August 10, 1868.

The patentee takes a narrow slip of tin which he fastens by paste or otherwise along one side of the mouth of a bag with the ends extending a little way on either side. The mouth is then bent to keep the bag open whilst being filled, and when so filled the mouth is again straightoned and folded over several times; the ends of the slip of tin are then bent back so as to secure the mouth of the bag.—Patent abandoned.

2494 B. Hunt, Lincoln's Inn. Eyelet machine. Dated August 10, 1868.
This consists in the employment of a series of annular recesses formed on the surface of a rotating cylinder, in which recesses are fitted sliding tubes that surround fixed cylindrical pins, thus forming circular spaces for the

reception of molten metal properly conducted to the same. A reciprocating longitudinal motion is given to the sliding tubes by means of crossbars to which they are attached.—Patent abandoned.

2495 B. HELLWAG, Greenock. Ship telegraphs. Dated

2495 B. HELLWAG, Greenock. Ship telegraphs. Dated August 10, 1868.

This consists in the employment of tubes filled wi h liquid which is acted upon by pressure from a cylinder. Piston rods are connected to index hands both above and below the deck. The movement of the index hand is governed by the amount of pressure exerted on the fluid.

—Patent abandoned.

2496 W. W. HUGHES, Porchester-terrace. Forcing air.

2498 W. W. Hughes, Porchester-terrace. Forcing air. Dated August 10, 1868.

The patentee makes a turbine or fan with two discs, one solid or close, the other open in the centre to admit the air. A ring is fixed round the outside of this opening to the disc, and revolves airtight in the front end of the casing. The spindle or shaft is fixed in the centre of the solid disc, and passes through the opening in the other end of the turbine or fan, without being attached to it, to an apright on which this end of the spindle which carries the pulley turns.—Patent abandoned.

2407 A V Newyon, Changaralang Stagm bolight. Dated

pulley turns.—Patent abandoned.
2497 A. V. NEWTON, Chancery-lane. Steam botters. Dated
August 10, 1868.
This consists in fitting a water tube outside the boiler.
The tube contains two floats, connected to a double lever;
when the water gets below a fixed level, one of the levers
opens a valve to which the whistle is connected.—Patent
completed

when the water gets below a fixed level, one of the levers opens a valve to which the whistle is connected—Patent completed

2498 D. Fauwinth, Norwood. Printing surfaces. Dated Angust 10, 1868.

The object of this is the production of metallic surfaces in relief, suitable for surface printing, in an ordinary printing press, by the combined use of photography with a process somewhat resembling in its main features the known glyphographic process, for the production from engraved plates of other plates or blocks with the design in relief. The patentee first produces, by any of the known photographic processes, a negative on glass, or any transparent substance. The success of the printing process depends mainly upon the negatives, and every means must be taken to render them as intense and as black as possible. The negative must be capable of giving positive impressions, by transmitting chemical rays of light, in the well known manner. With this negative, a reversed image is produced on a copper or any other metal plate, glass, or ebonite paper, or flexible substance, according to the work it is required to produce. To render the surface sensitive, and suitable to receive the photographic image, a paste is made, composed of bichromate of potash and a salt of soda or ammonia pulverized, and mixed with a solution of gum or organic substance, which is not soluble in alcoholic mixtres. This paste is mixed in one ounce of bichromate of potash, half an ounce of hyposulphite of sods, and half an ounce of hydrochlorate of ammonia, commonly called sal ammoniac. These ingredients are pulverized, and dissolved by means of gentle heat, in loz. of sibumen, 2 oz. of gelatine, and 2 oz. of Relatine, and 2 oz. of Novemberger glue, or best French transparent glue, dissolved in from two to three pints of water. This paste is spread evenly over the metal or glass plate, and artificially or spontaneously dried. The plate thus prepared is then to be brought in contact with the negative, in an ordinary photographic printing frame, and

Impression, which is capable of being transformed into a surface in relief. —Patent completed.

2499 R. Robinson, Preston. Regulating speed. Dated August 11, 1868.

The patentee provides two shafts, which, for distinction, may be called first and second motion shafts; these shafts are placed at suitable distances, in parallel line with each other; upon each of these shafts is fixed a band pulley, in each half of which a key passes, and is recurely fastened thereto; through one half is passed a right, and through the other a left-hand screw; these are passed up the centre to the outer end of each shaft, and secured at the end by collar and plate, free to revolve, and long enough to admit of change wheels where required. On the end journal of each shaft is fitted a tooth or worm wheel, free to revolve; this wheel may be made round on the rim for convenience of turning by hand if required. A band is placed on the expanders of both the first motion shaft while closed, and over the second motion shaft will be increased in velocity; then by gearing the second motion shaft will be increased in velocity; then by gearing the second motion shaft with any machinery, any necessary variation of speed may be obtained in proportion to the runge or sizes of the expanders.—Patent abandoned.

2500 W. H. Hunt, Liverpool. Baskets. Dated August 11,

2500 W. H. HUNT, Liverpool. Baskets. Dated August 11

This consists, first, in carrying the arched hoop, which forms the handle, down outside the mouth frame of the basket, instead of inside. By this construction, an increased internal space is obtained. Second, in making the covers of two pieces, and hinging or jointing them to the two longest sides, in order that the covers may be opened to the full size of the mouth of the basket.—Patent abandoned.

the full size of the mouth of the basket.—rarent acandoned.

2501 J. Brown, S. Stockton. Rolling iron. Dated August 11, 1868.

This consists in arranging two series of rolls one in advance of the other. The rotation of each series is in advance of the other. The rotation of each series is in a direction opposite to that of the adjacent series. Thus, when each series consists of four rolls, they are arranged in the following manner.—The first pair of rolls rotate in a direction proper to take the bloom, or slab, or pile from the workman, and, after having passed through the rolls, to deliver it into a second pair immediately in front of the first pair having rotation in the same direction, but driven at a higher or greater speed than the first pair. The bloom or slab is then returned through a third pair of rolls, the axes of which are in a line with the axes of the second pair, but which third pair rotates in a direction opposite to that in which the first and second pairs rotate. The bloom, pile, or slab is delivered by the third pair of rolls to a fourth pair, whose axes are in line with the first pair, and which rotates in a direction similar to that of the third pair. The slab, pile, or bloom, having been passed through four pairs of rolls, is delivered back to the workman at that side of the system of rolls at which it was introduced.—Patent completed.

2502 A. M. CLARK, Chancery-lane. Propelling vessels.

Dated August 11, 1868.

The patentee proposes to inject steam at a high pressure, from a suitable boiler, through an apparatus composed of several cones—to which the water has free access—disposed one within the other at the bottom of a vessel, which steam carries with it a column of water of sufficient diameter to produce, by its reaction on the surrounding water, sufficient power to propel the vessel.—Patent completed.

2503 I SALMON Manchester. Printing mechings. Dated

2503 J. SALMON, Manchester. Printing machinery. Dated

pleted.

2503 J. SALMON, Manchester. Printing machinery. Dated August 11, 1868.

This consists in an improved arrangement and combination of mechanism by which the cards are set in position for printing, printed, and delivered from the machine; and also the type inked and the inking roller fed with fresh supplies of ink; all these operations being performed self-acting. The cards are laid in a pile one above another on a table. Underneath the pile a small feeder is caused to move to and fro, at each forward movement taking a card from underneath the pile, and delivering it over the place where it is printed. As the feeder recedes after delivering the card, the former rises and prints the card. When the card has been printed, it is forced out by the following card being pushed in, and falls into a shoot consisting of adjustable inclined planes set in such a manner as to turn the card over and cause it to fall with the printed side uppermost. As the printed card passes off, the inking roller is caused to pass over the forme, giving it the necessary supply of ink for the next impression, and, continuing its motion, comes in contact with a disc, from which it takes up a freeth supply of ink, the disc being caused to change its position each time the roller passes across it, so as to present a fresh surface to the roller at each stroke.

—Patent completed.

2504 H., T. and G. Moors, Birmingham. Cornices, pele, the card angust 11 1868.

-Patent completed. 2504 H., T. and G. Moore, Birmingham. Cornices, poles, c. Dated August 11, 1868. Cornices are made with tablets or panels of glazed are cemented to a wood back. Poles and rods are made f earthenware (tubular or solid).—Patent abandoned.

of earthenware (tubular or solid).—Patent abandoned.

2505 M. Gray and F. Hawkins, Woolwich. Tetegraph
wires. Dated August 11, 1868.

The wires are covered with a secondary, or it may be a
primary, insulating coat of plastic compound by employing pairs of pressing or squeezing rollers, formed with
several half-round ring grooves placed side by side, and
having as projections that separate the grooves blunt
edges or compressing rings. Between these rollers are
passed a number of wires—to be coated—corresponding
with the number of grooves provided in the rollers; and
with the wires are passed in two ribbons or fillets of the
compound india-rubber, one above and the other below
the wires, such ribbons being of a width suitable for
covering all the wires or enclosing them in rubber. By
the action of these rollers, the rubber is pressed upon and
around the wires, and caused effectually to coat the same
without waste.—Patent completed.

2506 J. H. Johnson, Lincoln's Inn. Permanent way.

without waste.—Patent completed.

2506 J. H. JOHNSON, Lincoln's Inn. Permanni way.
Dated August 11, 1868.
This consists of a new form of rail which is provided
with a safety flange to prevent the wheels running off the
line. Upon this new rail is applied a sheathing composed
of steel plate, over which the rolling stock runs, and
beneath the sheathing there is disposed a pad or cushion,
the object of which is to deaden and neutralize the shocks
to which it is subjected. The rails thus composed of two
principal parts, and forming the movable part of the permanent way, are supported on wrought-iron arches, castiron chairs, and sleepers connected together.—Patent completed.

pleted.

2507 A. ARGAMAKOFF, Stockwell Green. Printing in relief. Dated August 11, 1868.

This consists of the following ten operations:—1. Covering plate glass with a layer of gelatine. 2. Drying the gelatine layer. 3. Preparing the gelatine layer, £e., making it sensitive to light, and incapable of dissolving when the gutta-percha is poured on it. 4. Exposing it to the light under a photographic negative or positive taken on thin paper. 5. Revealing the drawing by means of a moist surface (glue or gelatine). 6. Impressing the drawing on gutta-percha. 7. Increasing the relief of the gutta-percha plate by hand. 8. Obtaining the copper matrix. 9. Obtaining the copper plate or printing surface in relief (cliche). 10. Increasing the relief of the copper plate or the cliche by corroding the ground.—Patent completed.

2508 J. MFARLANE, Edinburgh. Papermaking maching.

2508 J. M'FABLANE, Edinburgh. Papermaking machines Dated August 11, 1868.

Dated August 11, 1868.

This consists in constructing the upper and under couch rollers with an iron shell covered with vulcanite and india-rubber of suitable thickness, the vulcanite being fixed upon the iron shell, and a covering of vulcanized india-rubber fixed upon or over the vulcanite, by which means a perfect junction is secured—Patent completed.

2509 This invention is under opposition, therefore the documents cannot be seen.

documents cannot be seen.

2510 E. P. G. HEADLY, Cambridge. Watering roads.
Dated August 12, 1868.
Upon a suitable locomotive frame, to be propelled by
hand or otherwise, the patentee mounts a windlass or
drum, the axis of which is hollow. Upon this drum any
required length of flexible tube or pipe is wound, one end
of which is connected with the hollow axis of the drum
upon which it is wound; the free end of the tube is litted
with connections for attaching it to hydrants or standards
supplying water under pressure. To the hollow axis of
the drum suitable distributing media are attached. The
axis is litted with a handle for winding the pipe, which
runs off as the frame is moved on again when required.
—Patent completed. Patent completed.

—Patent completed.

2511 D. HILL, J. RICHARDSON, G. N. DUCK, C. E. JOHNSON, and W. F. MASTERMAN, Stockton on-Tecs. how and steel. Dated August 12, 1868.

This consists in the use of srtificial compositions in the refining of iron and steel. One class of composition is formed by taking any natural iron ores, or iron stones, or ferruginous bodies, comparatively free from phosphorus and sulphur and their oxides and compounds, and melting the same, either singly or in combination. Class two is prepared by taking one or more of the substances previously mentioned as entering into Class one, and melting the same, either singly or in combination, together with scrap iron, for the purpose, into a mass which is more or less homogeneous. Class three is formed as follows:—Any natural iron ores, iron stones, or artificially obtained forruginous bodies, having been melted and prepared as before described, with reference to Classes one and two.

with or without the addition of scrap iron and siliceous matter, a compound is formed therewith as follows: One or more of the heavy metals, such, for instance, as lead or manganese, or any alloy, amalgam, oxide, or salt of such metals, alkalies, or alkaline salts, or any hallod body, or any mineral or minerals, or artificial body ar bodies, or organic substances, containing the same or one or more of them, or the waste products from stills, in which chloriue has been prepared, are charged along with one or other of the ferruginous compounds before described, into any suitable furnace, vessel, or apparatu and the whole melted together into a mass which is more less bonogeneous. After being sufficiently heated they are removed in any convenient manner from the furnace, vessel, or apparatus employed, and while still in a bot state, or after being cooled, charged with pig iron in the refinery, or with refined plate or pig iron in the puddling furnace, or in any furnace, vessel, or apparatus in which the manufacture of iron or steel is conducted, the result in either case being that the iron or steel is more or less purified, and the qualities of the same improved in a very high degree.—Patent completed.

2512 J. WINSBORROW, Dalston. Motive power. Dated

August 12, 1868.
For this purpose pistons work perpendicularly in cylinders open at each end into separate chambers, which are supplied through passages and slide valves operated from a rotary axis, having motion given to it by bevelled from a rotary axis, having motion given to it by bevelled for other suitable gear connected to the piston rods. Gearing communicates motion to the index wheel work for registering the motions of the pistons, and consequently the amount of liquid measured. By these means, the use of stuffing boxes to the piston rods is rendered nunccessary, and the friction and wear consequent thereon is avoided. The liquid to be measured passes into the valve chamber, and thence through the alternate ports of the valves to the respective ends of the cylinders. The outlet for the measured liquid is through the valve chamber and by a central port.—Patent completed.

2513 J. S. PENDLEBURY, Bury, Steam pumps. Dated August 12, 1868. For this pu

2513 J. S. PENDLEBURY, Bury. Steam pumps. Dated

2513 J. S. PENDLEBURY, Bury. Steam pumps. Dated August 12, 1868.

Upon the sides of the valve spindle are formed inclined planes in opposite directions upon which springs act, small friction rollers being interposed. The effect of these inclined planes and springs is, that the spindle must move in either one or other direction to the end of its stroke, and cannot stop at any intermediate positi n. A lever actuated by an arm on the piston rod imparis motion to the valve spindle until the apex or the junction of the inclined planes is pushed just beyond the point where the spring acts, and the spring then completes the stroke.—Patent abandoned.

2514 J. THOMPSON, Handsworth. Utilizing iron. Dated

2514 J. THOMPSON, Handsworth. Utilizing iron. Dated August 12, 1868.

The object is the utilization of ends or heavy scraps cut from the ends of rails. These scrap ends usually average from lft. to 15in. long, more or less. These are treated by rolling in the mass.

The lump is first heated and passed between rolls, which has the effect of dividing the mass into as many divisional parts as may be suitable; by subsequent working and reduction they are reduced down to desired sizes for rolling.—Patent abandoned.

2515 J BROAD, London Bridge. Treating fibres. Dated

2515 J Broad, London Bridge. Treating fibres. Dated August 12, 1868.
This consists in constructing cast-iron cylinders hollow to admits steam therein; on the external part are steel pins, so that when the cylinders are put in motion the fibrous material is acted on by them; the steel pins on are made with a cutting edge, or they may be pointed, so as to have the effect of dividing or separating the fibrous material. either animal, vegetable, or mineral, into a pulp, is a vessel made sufficiently strong to admit of steam being introduced therein for the purpose of acting on the fibrous material is submitted to the action of caustic soda, wood ash, and blue lias lime concentrated with spirits of salts.—Patent abandoned.

Patent abandoned.

2516 H. H. Henson, Westminster. Metallic ropes, Dated August 12, 1868.

This consists in employing the wire or wires for such ropes in their natural ungalvanized and consequently unwakened state, and providing them either before or during the process of rope making with a protective coating of tape, jute, hemp, or fabric, and a preparation of "Hay's glue," carbonized oil, or some other suitable bituminous or other material or compound that will effectually exclude moisture and grit.—Patent completed.

2517 C. D. J. SEITZ, Lancaster, Furnace. Dated August 12, 1863.

The patentee mixes a small quantity (say, about 25 per cent, to the soda contained in the lyes) of quicklime, with the waste lyes, which makes the residuum open and pomus, and thus allows sufficient atmospheric air to come into contact with all parts of it, and to freely burn off the resinous and gummy matters.—Patent abandoned.

2518 J. WILSON, Salford. Blinds, sun shades, &c. Dated August 12, 1869.
This consists in the adaptation and employment of expanding and contracting arms, similar to lazy longs, for moving blinds out and in, and making them self-supporting without the use of stays or pillars.—Patent completed.

2519 R. H. SOUTHALL and W. HALLAM, Manchester, Boots and thoss. Dated August 12, 1868.
Guards for side springs are formed of soft leather; each guard is made in two parts, or in one piece folded and tightly stitched to the side of the leather forming the upper of the boot.—Patent completed.

upper of the cook.—Fatent completed.

2520 H. J. W. and R. DEWHURST, Huddersfield.

Ornamenting seal skins. Dated August 12, 1863.

This relates to the production of painted seal skin cloths
of any width by mechanical means.—Patent completed.

2521 LUNN, Horncastle. H Envelopes. Dated

2521 H. LUNN, Horncastle. Envelopes. Dated August 12, 1868.

The bag is closed along three sides, and is provided with a closing flap on the fourth side, which flap has a tongue formed thereon or secured thereto, having an enlarged extremity. A slip of cardboard, or other stout material, is let into or secured upon the body of the bag or envelope, and the expanded end of the tongue is passed through or under it, the expanded portion of the tongue having been first folded down at the sides so as to enable

it to pass through or under the slip and then opened out again so as to effectually retain the tongue in its place and keep the flap closed.—Patent abandoned.

2522 J. CLEAVER, Nottingham. Metal covered lace, Dated August 12, 1868.

The surface of the bobbin net or other fabric is dressed with a strongly adhesive material upon which small pleces of sheet metal are sprinkled, and to which they adhere as they fall.—Patent abandoned.

adhere as they fall.—Patent abandoued.

2522 R. C. RAPIER, Westminster. Electric clocks.

Dated August 12, 1863.

wo or more breaks are employed for the purpose of making simultaneous contact, the object being to secure certainty of action. In order to hang a pendulum, a bar of steel or other metal, with one edge turned up, is supported on a frame. The pendulum stem does not reach quite up to this bar, but is suspended on it by two cheeks or plates fastened to the sides of the stem of the pendulum. This bar is fitted with a stud or pin midway between the checks, and on this pin turns a friction roller which offers far less resistance to the working of the pendulum than any kind of dead collar would do.—Patent abandoned.

doned.

2524 H. B. WALKER, Bradford. Extracting burns from wool. Dated August 12, 1868.

The patentee first steeps the wool in a bath of sulphuric acid and water which varies in strength according to the class of wool under treatment. The wool is then passed through rollers (by preference fluted) to crush the burns and squeeze out the acid and water. It is then spread for a short time on the floor to cool, and to allow the air to act on it; it is then dried upon steam pipes or other means. When perfectly dry, it is "willyed," to knock out the burns.—Patent abandoned.

2535 W. PANNE Bellem. Steam cocks. Dated.

when perfectly dry, it is "willyed," to knock out the burrs.

—Patent abandoned.

2525 W. PAYNE, Balham. Steam cocks. Dated August 12, 1868.

The barrel of the cock is provided with a branch finlet pipe communicating with the upper chamber; this chamber is formed with an open top, within which a screw thread is cut to receive a screw plug. A coulcal seat is cut in the chamber as abort distance below the inlet for the reception of a valve, the diameter of which is less than that of the chamber, so as to leave an annular space between the two, and the upper surface of the valve is provided with a guiding stem extending into a corresponding cavity or recess cut in the screw plug or cap of the chamber, in order that the valve may be enabled to rise and fall within the chamber, the faces of the valve always maintaining the same plane. The lower surface of the valve is extended by a shoulder and terminated by a projection in line with the stem, reaching nearly to the centre of the bore for the plug. The plug is then formed tapering cylindrically at each end, but midway where it intersects the chamber a segment is cut away on each side of the cylinder, thus leaving corresponding openings or spaces when the plug is turned down by the handle to close the chamber, but when the handle is turned back the two remaining arcs of the plug fit the lateral portion of the bore i; in this closed position of the cock, the lower extremity of the valve descends into the space left in the plug by the removal of the segment, and the valve becomes securely seated; but when the plug is opened, the arc of the plug assumes a position transversely to the chamber, and rising upwards by its rotation, elevates the valve from its seat and permits the flow of steam.—Patent completed.

2526 G. A. BUCHHOLZ, Shepherd's Bush. Hulling grain.

and rising upwards by its rotation, elevates the varie from its seat and permits the flow of steam.—Patent completed.

2526 G. A. Buchholz, Shepherd's Bush. Hulling grain. Dated August 12, 1868

The bulling machine consists of a cylindrical case fitted at its opposite sides with panels of wire gauze or pierced metal to facilitate ventilation within, and armed on its inner periphery at the parts not occupied by the panels with sets of steel blades fixed radially in segmental groups. Within the cylindrical case is mounted a series of drums, which are keyed upon a central rotating shaft. These drums are armed on their peripheries with blades made like those on the case of the flat steel plates. The drums are cast with radial wings extending from the boss to the periphery, and holes are formed through the drums to allow of a down draft being created and distributed through the case by the wings as the drums are rotated. The drums, instead of being enclosed, as heretofore, in separate cylindrical chambers, have interposed between them horizontal rebated ring plates, which form part of the case. The ring plates, and also the bottom plate of the case, are cast with annular flanged projections, which are intended to receive steel blates rebated at the tack to fit the flanged projections.—Patent completed.

2527 J. Petrie, Rochdale. Washing tool. Dated

2527 J. Petrie, Rochdele. Washing wool. Dated August 12, 1868.

A rake is euclosed in a washing vessel, and is mounted upon a ball or other joint carried by a lever or levers, an arm of which turns upon a centre and carries a balance weight. The vibratory motion is imparted to the take by a crank.—Patent abandoned.

a crank.—Patent abandoned.

2528 W. E. NEWTON, Chancery-lane. Photographic frames. Dated August 12, 1863.
This consists, first. in making a card, or card frame, of paper or other material, having an opening through it for exhibition of the picture, and framed with an embossed border round the opening. The card or frame is produced simultaneously by cutting and punching the paper in a press. The invention further consists in a combination with automatic feeding devices for feeding a continuous strip of paper under the cutters and punches in regular succession. The paper is fed by a pair of rollers unler a tamping press, the head of which has an up-and-down notion imparted to it by means of a cam working in a rectangular slot in the crosshead.—Patent completed.

2529 R. Sim Nanles. Preserving shins bettom.

2529 R. SIM. Naples. Preserving ships bottoms. Dated August 1?, 1868.
This consists in employing a mixture of iodine and red iodine of mercury made into a paste or composition.—Patent completed.

2530 F. BARNETT, Paris. Swimming apparatus. Dated

2530 F. BARNETT, Paris. Swimming apparatus. Dated August 13, 1868.

The patentee purposes to use what he calls "human tins," having the properties of fishes fins, and at the same time answering the purposes of the feet of aquatic birds. The hands of a swimmer are titted with extensive membranes, which are both firm and supple and rigid, in one sense. These membranes are composed of india rubber, or any other substance, of such a thickness as to permit them to be perfectly pliable between the fingers when desirable to close them and the thumb against each other.—Patent completed.

2531 W. THOROLD, Norwich. Railways, Dated August 13,

1863. One single line of rail is arranged in the middle of the roadway. The rolling stock is constructed with four bearing wheels, with double flanges, all in one line in the middle, underneath each carriage or truck, instead of having bearing wheels placed on each side. Traversing screws and gear are employed for shifting the wheels laterally relatively to the body of the carriage or truck, until the load is perfectly balanced upon the wheels. The perpendicular position is preserved by the addition of one or more wheels on each side of the carriage or truck, so arranged, by working in slots, to run freely cut the road, without bearing any part of the weight of the carriage or truck, except when the carriage or truck inclines to one side or the other.—Patent abandoned.

2532 R. SAUNDERS, Croydon, Anchors. Dated August 13.

2632 K. SAUNDERS, Croydon. Ancore. Dated August 18, 1868.

The shank is made in two parts, that next the crown end of a bar of iron, with a slot in one end, and a large orifice at the other. This orifice is circular at the top, and gradually tapers towards the bottom, where the arms enter, and work freely upon the inner rim of the collar, thereby obviating of jectional friction in the orifice. The cable end of the shank is composed of rubber or other elastic discs and washers of iron, alternately arranged in a metal frame, with a drawbar passing through their centre, and these are securely held in uniform position by a strong nut or other reliable fastening on the end of the drawbar bearing on the top of a strong travelling plate. By means of this elastic part of the shank, all sudden jerks are mitigated when bringing up or riding at or weighing anchors.—Patent completed.

2533 J. Grant. Hamostead. Music stands. Dute1

anchors.—Patent completed.

2533 J. Grant, Hampstead. Music stands. Dated August 13, 1863.

The patentee forms a right-handed screw upon a straight spindle; the screw has as many turns as may be convenient of a very deep thread, the spaces between each turn of the thread and the next being intended to receive one of the leaves required to be turned over, so that the number of leaves with which the screw can be charged at the next three leaves thread the depend upon the number of number of leaves with which the screw can be charged at one time must necessarily depend upon the number of such spaces. A short projection or thumb is connected to the spindle, and projecting outwards from it. As the spindle is turned by a rod and treadle worked by the foot, the projection moves up between the leaves, and by continuing motion, a leaf is turned over from one side to the other.—Patent completed.

the other.—Patent completed.

2534 J. M. MILLBANK, Connecticut, U.S.A. Firearms and cartridges. Dated August 18, 1868.

To the side of charging chamber, a lever is fitted. A toothed quadrant in connection with the lever draws back the striker, which is held in that position by the trigger, as usual. The cartridge case is fitted with a flanged base, acp is placed in the centre, an indent is made in the cap for the fulminate to lodge in the crease. The powder is free to enter the cap, and the certainty of ignition is ensured by the base of the cap being smashed up.—Patent completed.

2535 B. INGHAM, Bradford. Dyeing warps. Dated August 13, 1861.

This consists of a rectangular box or vessel to contain the dye liquor, having a roller at each end out of the vessel to wind the fabric on and off, from one to the other. The box is also fitted with one or more other rollers, to conduct the fabric through the dye liquor.—Patent abandoned.

doned.

2536 H. STEFFANSON and J. HADLEY, Upper Thamesstreet. Decorticating grain. Dated August 13, 1868.

This consists of a series of roughened rotating arms or blades, mounted on a central shaft or spindle, in a cylinder, to which the grain to be operated upon is admitted, by preference, in a continuous stream, and from which it is discharged, after having been sufficiently long exposed to the decorticating action of the roughened blades.—Patent completed.

2537 J. HOLDING, Lancaster. Healds. Dated August 13

1866.
This consists in making healds of two distinct substances or materials, such as metal, for the top portion, that is from the eye upwards, so as to embrace the top heald stave and fibrous material, downwards, so as to embrace the bottom heald stave.—Patent abandoned.

2538 S. C. LISTER, York. Combing wool. Dated August 18,

1868.

The teeth of the cards that first act upon the fibre are longer and coarser than those on the finishing side; the teeth are made with round wire. Combs are employed in place of cards. The combs are made coarse at one end and finer at the other. They are mounted on an endless chain; each comb travels in a groove their motion can be controlled, and made to enter the wool at right angles to the nip, and draw through the wool or fibre nearly horizontally.—Patent abandoned.

201tally.—Fatest abstractioned.

2539 S. R. CRAMPTON, Westminster. Grinding coal.

Dated August 13, 1868.

This consists in grinding coal, by means of ordinary mill stones, in combination with an artificial current or blast of air, between the grinding surfaces, produced either by a blast or by a powerful exhaust, acting as an inverted blast.—Patent completed.

2540 H. K. YORK, Cardiff. Treating iron. Dated August 13, 1861.

According to this invention, the parentee reduces metal by means of teeth, formed of short pieces of bur steel or iron, which are held at the ends in two discs mounted on an axis. The iron or metal to be reduced is prescuted (usually when hot) to the teeth, by introducin it between two discs, in a radial direction; the metal is no steel it of a guide through, and is pressed forward towards the centre of the discs, so as to cause it to bear against the teeth, by a plunger, actuated by a hand lever, or tongs may be used to carry the metal forward.—Patent completed.

#### APPLICATIONS FOR LETTERS PATENT.

Dated February 23, 1869. 557 J. T. Gaze and J. Hymas, Erith. Improvements in 1558 A. Johson, Darlington. Improvements in the ma

chinery or apparatus for discharging, and in the arrangement and construction of coke ovens, also in the mode ment and construction of coke ovens, also in the mode of utilizing the waste heat of coke ovens. 559 J. Breeden, Birmingham. Improvements in taps

or stop-cocks.

560 J. Johnson and W. Gill, Unstone, Derbyshire. Im-

560 J. Johnson and W. Gill, Unstone, Derbyshire. Improvements in rotary engines and pumps.
561 B. W. Farey, Bermondsey. Improvements in the seatings or facings of gas valves.
562 W. F. C. Mourie, Southampton-row, Middlesex. Improvements in pianofortes.
563 J. Neilson and J. Marshall, Glasgow. Improvements in applying trade marks, names, and devices upon metallic capsules.

mental capsules.

564 A. V. Newton, Chancery-lane. Improvements in the tire-boxes and ash-pans of locomotive engines.

565 S. Holroyd, Newton Heath, Manchester. Improvements in the recovery of substances used in the purification of gas for illumination, and of waste products arising therefrom.

therefrom.

566 H. Bessemer, Queen Street-place, Cannon-street,
City. Improvements in the construction and arrangement of machinery, apparatus, and buildings employed
n or for the manufacture or production of east steel and
malleable iron from pig or other carburet of iron.

malleable iron from pig or other carburet of iron.

Dated February 24, 1869.
567 W. E. Gedge, Wellington-street, Strand. An improved hand vice.
568 J. J. Myers, Caxton Iron Works, Spa-road, Southampton. A novel method of enabling passengers to warn railway servants in charge and during the running of a train of anything dangerous to their lives and welfare, and to indicate to the guard promptly the carriage and compartment from which such warning shall have been caused, also to enable the driver to know immediately if any pertion of his train of carriages has broken away or been disconnected from any cause.
569 J. Whitehead, Middleton-road, Oldham. Improvements in furnaces for steam boilers and other purposes.
570 W. A. Ives, New Haven, Connecticut, U.S.A. Improvements in mechanism for making circular tenoms and mortises.
571 W. Williams, Mitford-street, Liverpool. Improvements in laying and joining pipes for cother like purposes.

provements in mechanism to and mortises.

571 W. Williams, Mitford-street, Liverpool. Improvements in laying and joining pipes for gas, water, and other like purposes.

572 J. Cooke and G. Hibbert, Richmond, Yorkshire. The use of one or more steam jets with or without water for obtaining vacuum power, applicable to steam and other motive engines, also to other purposes in paper, chemical, iron, steel, and other works and inaunfactures.

573 B. Hunt, Serle-street, Lincoln's Inn. Improved apparatus for regulating friction on the bobbins of machines used for spinning cotton and other fibrous materials.

eriais. 574 J. I. Vaughan, Mitro-lane, near Kensal-green. 574 J. I. Vaughan, Mitro-lane, near Kensal-green. Improvements in treating, converting, and utilizing the metallic saits and sulphuric acid contained in, or derived from, the residual or waste liquors of tinned plate works and petroleum and parafiln refineries.

575 R. Morton, Bridge House, Nine Elms. Improvements in apparatus used in the manufacture of gas.

576 G. Rees, Holloway. Improved means of producing designs and devices upon the surface of glass and glazed

ware. 577 J. T. Griffin, Fleet-street, City. Improvements in harvesting machines.

577 J. T. Griffin, Fleet-street, City. Improvements in harvesting machines.

Dated February 25, 1869.

578 W. H. Tooth, Greenwich. Improvements in the manufacture of bricks, ties, and other articles made from plastic or silicious materials, and in the machinery or apparatus employed for moulding and pressing the same, part of which improvements are also applicable for compressing peat or other substances for the manufacture of artificial fuel.

579 E.A. V. Lerol, Rue Ste. Appoline, Paris. Improvements in the work produced by cards of carding engines.

580 W. Anyon, Manchester. Improvements in the construction of velocipedes.

581 H. Lowenberg, Chancery-lane. A new or improved compound to be used in the manufacture of hats, bonnets, and other articles of wearing apparel, and the means employed therein.

582 B. P. Walker, North-road House, Wolverhampton. Improvements in shaping and fluishing metallic and other articles by abrassion, and in the machinery or apparatus employed therein.

583 W. Turner, Hammersmith, Dublin, and J. W. Gibson, Dundalk, Louthshire. Improvements in friction rollers applicable to rolling bridges.

584 J. Moody, Heworth Green, Yorkshire. Improvements in the means and apparatus for mooring vessels or floating bodies.

585 W. Parkinson, Gloucester-grove West, Old Bromp-

floating bodies.
585 W. Parkinson, Gloucester-grove West, Old Bromp-

585 W. Parkinson, Gloucester-grove West, Old Brompton. Improvements in wood-cutting machinery.
586 W. E. Newton, Chancery-lane. Improvements in furnaces and apparatus for oxidizing and desulphurizing iron and other ores.
587 E. D. Barker, Weston-super-Mare, Improvements in apparatus for actuating railway brakes.
588 L. Engel, Mumford-court, Milk-street, City. Improvements in parasols and umbrellas or sunshades.
589 F. Brady, St. John's-terrace, North Gate, Regent's Park. Improvements in switch apparatus for railways.
590 W. R. Harris, Rue Gaillou, Paris, Improvements in the manufacture of weavers' harness or healds, and in the machinery used for that purpose.

Dated February 26, 1869.

Dated February 26, 1869.

591 W. T. Eley, Gray's Inn-road. Improvements in the onstruction of cartridge cases for breech-loading fire-

construction of carriage cases for School and Sams.

592 H. J. Ledger, Manchester. Apparatus applicable to railway carriages for enabling presengers to signal to the guard and driver of a train, and at the same time to communicate with, and receive assistance from passengers in any other compartment of the same carriage.

593 H. Harburg, Hatton-garden. Improvements in musical boxes.

594 T. Moore, South Stockton-on-Tees. Improvements in machinery ifor obtaining and applying power, appli-

594 T. Moore, South Stockton-on-Tees. Improvements in machinery for obtaining and applying power, applicable to the raising and lowering of weights, and to all other purposes where power is required.

595 W. R. Lake, Southampton-buildings, Chancerylane. An improved method of constructing ships and other vessels for carrying liquid cargoes.

596 J. Cheetham, Chadderton, Lancashire. Improvements in the form and manner of winding yarns, whether single or multiple, for convenience of carriage, and for facility in unwinding in the after processes.

597 J. A. F. Suter, Hereford, and T. C. Hinde, Fownhope, near Hereford. Improvements in furnaces, and in the combustion of fuel for melting steel, and for other purposes where high temperatures are required.

598 G. J. Hinde, Wolverhampton. Improvements in coating iron or steel with copper or brass or other alloys of copper.

coaing iron or steel with copper or brass or other alloys of copper.

#g.99 J. T. H. Richardson, Tutbury, Staffordshire. An improved method of cutting flint glass, such as is used for wines, goblets, tumblers, or other table glass, or for lamp or other glasses of a circular or oval shape, and in apparatus to be employed therefor,

600 J. Townsend, Glasgow. Improvements in extracting and in refining oils and other products from mineral and other materials containing carbon and hydrogen, and in apparatus therefor.

601 E. Falck, Cheapside, City. Improved apparatus for distributing liquids in a state of spray.

602 J. Reap and W. H. Michelmore, Borough-road, Southwark. Improvements in spring hinges.

603 C. Markham, Brimington, Derbyshire. Improvements in steam and other boilers.

604 W. A. Herring, Chertsey, Surrey. Improvements in pumps.

604 W. A. Herring, Christoff, 2015.

in pumps.
605 C. Williams, Sandy Hill-road, Plumstead, Kent. Improvements in apparatus for obtaining motive power.

Dated February 27, 1869.
606 J. Adams, Arlington-street, Sadler's Wells. Improvements in the means of communicating and signal ning between passengers, guards, and drivers of railway

trains.
607 W. Thomas and W. Davis, Aberdare. An improve-ment in the construction of winding machinery or appa-ratus employed in mines, shafts, pits, or lifts and inclined

ratus employed in mines, sharte, proceedings of the planes.

608 J. R. Croskey, King William-street, City. Improvements in looms for weaving.
609 R. Pyne, Wellington-street, Strand. An improved railway buffer carriage.
610 J. H. Johnson, Lincoln's Inn-fields. Improvements in machinery or apparatus for measuring raw silk.
611 C. Maw, Aldersgate-street, City. Improvements in cartridges for firearms and ordnance, and in torpedoes and similar explosive engines.

out C. Maw, Americane-street, City. Improvements in cartridges for firearms and ordnance, and in torpedoes and similar explosive engines.

612 T. S. Blair, Tavistock Hotel, Covent-garden. Improvements in the means and apparatus or machinery for effecting the mixture of molten cast from with solid oxides and other bodies.

613 E. Chapman, Green Dykes Mills, Egremont, Cumberland. Improvements in carding engines for flax. hemp, tow, jute, wool, and other fibrous substances.

614 T. Atkinson, Bradford. Improvements in means and apparatus for lighting domestic and other fires.

615 R. S. Norris, Liverpool. An improved method of getting coal, and for the machinery or apparatus connected therewith.

616 G. J. Snelus, Dowlais, Glamerganshire. An improved mode of, and means for reducing transcess.

getting cost, and for the machinery or apparatus connected therewith.

616 G. J. Snelus, Dowlais, Glamorganshire. An improved mode of, and means for, reducing iron ores.

617 L. G. Lysons, Meadow Bank Cutts, Aberdeen. Improvements in apparatus for signalling from the marker's
butt and firing party respectively, in rifle, carbine, or
artillery practice.

Dated March 1, 1869.

618 P. S. Regnauld, Paris. An improved mode of, and
apparatus for, fixing the lid and the bottom of tin canisters,
preserve, or other boxes to the body of them.

619 J. Ladley, Leeds. Improvements in machinery or
apparatus for spinning and twisting wool or other fibrous
substances.

apparatus for spinning apparatus for spinning substances.
620 R. J. Goodbody, Charville-square, Tullamore, King's County, and R. E. Donevan, Ashgrove House, Upper Rathmines, Dublin. Improvements in treating tobacco, and in apparatus employed for that purpose.
621 J. Rust, Lambeth. A new and improved composition specially applicable for use for pictorial and decorative nurposes.

sition speciary approach.

1 tive purposes.

622 W. E. Gedge, Wellington-street, Strand. Improvements in breech-loading firearms and in cartridges.

623 W. Simpson and A. Gardner, liford, Essex. Improvements in the construction of engines worked by

provements in the construction of engines worked by steam or other motive power.

624 A. H. Brandon, Rue Gaillon, Paris. Improvements in metallic cartridges, and in the methods of manufacturing the same.

625 W. R. Lake, Southampton-buildings, Chancery-lane. An improved lawn mowing machine.

626 D. Davies, Crumlin, Monmouthshire. Improvements in apparatus for getting coal, stone, slate, or mineral.

mineral.
627 J. Cliff, Runcorn. Improvements in the use and application of certain materials to be used as a substitute for fire-bricks.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to Riobertson, Broman, and Co., Patent Department, 166, Fleet-street, London, E.O., to whom all communications upon the subject should be addressed.

LONDON: FRIDAY, MARCH 12, 1869.

#### REVERSING STATIONS.

CHORTLY after the introduction of railways, when the locomotive mania was at its climax, it was little thought that the anticipations indulged in, the extravagant ideas entertained of its universal applicability, and entertained of its universal applicability, and the exaggerated notions of the loads to be drawn, and the velocity to be acquired, would ever have dwindled down to their present humble pretensions. It has been found impossible to carry out in their integrity the principles originally enunciated as governing the formation and the safe working of railways. Experience, moreover, has shown that with a diminution in the speed, steeper gradients and sharper curves may be employed with perfect safety than those which were assumed by the fathers of steam locomotion to constitute the limits of security. Stephenson was of opinion that no railway curve should have a radius less than a mile. What would he say if he saw engines running round the arcs of circles, of which the radii scarcely equal a quarter of that dimension?
As might be naturally conjectured, the first lines of railways were laid out through the most favourable districts, and those routes presenting the greatest advantage were eagerly seized upon by the engineers, who left their successors to make the best of what was left them. It was not, therefore, until rival lines began their existence, that it became evident that some departure from the orthodox plan of proceeding was absolutely necessary. This was indulged in at home to an extent far greater than what would at one time have been considered possible, but no sooner were railways transplanted, so to speak, to foreign countries, than a new system of formation was introduced which has completely inverted the original arrangement. So far as gradients are concerned, the St. John's Wood line, with its two mile gradient of 1 in 27, can challenge comparison with any mountainous railway that exists, and there are not wanting others in our own country in which the curves are so sharp as to forbid their being traversed at any other pace than that of a walk. Still, we have generally contrived to get from one level to another by proceeding in the same direction, notwithstanding that a good deal of winding and twisting may be necessary in order to reduce the gradient as much as possible. In mountainous countries, especially in India, where for a long time the lofty ghauts presented an impassable barrier to the inroad of civilization, it was soon discovered that it was practically impossible to rise sufficiently by the employment of the usual gradients and curves. Let the former be rendered as steep as locomotive agency would permit, and the latter as sharp as the slowest pace and the minimum of safety would allow, yet it was not possible to "get up the hill." In this emergency it became necessary to surmount the difficulty by successive forward and backward steps, as it were, and in this manner to gain the height required. Thus it was that reversing stations came into use, the nature of which we will now direct our attention to.

Everyone is familiar with the manner in which a horse, with a heavy load behind him, goes up a hill. Instead of proceeding in a straight direction, he climbs the ascent by a straight direction, he climbs the ascent by a laternative. The only rival safeguard against scries of diagonal or zig-zag lines, thus such accidents is a large amount of brake power, and, even in particular instances, not be carried out by the American upon the same principle that the trains are enabled to mount the sides of mountains, the enabled to mount the sides of mountains, the reversing stations or points being situated at would slide down the incline nearly as fast as which was formed some time since for the series of diagonal or zig-zag lines, thus reducing the steepness of the acclivity. It is upon the same principle that the trains are

the junction of every two diagonal lines. A glance at the accompanying diagram will demonstrate the advantages derived from this arrangement. There are, of course, some corresponding disadvantages which we shall allude to presently, but the chief of them can, with proper care, be provided for. Besides, there is in reality no choice in the matter. Unless the reversing principle be adopted, railway intercommunication cannot be established in mountainous and precipitous localities. Referring to the diagram, suppose

it be required to rise from A to B, and that by the employment of as many serpentine curves and of radii as sharp as possible, it is found that the distance between the two points cannot be made longer than 10,000ft. Let this distance be represented by the line A B, and let the point B be 600ft. above A. Since the distance between A and B 10,000ft., and the rise is 600ft., in order to rise from the lower to the higher level, the gradient would be equal to 1 in 16.6. This is too steep for any locomotive to accomplish, and consequently some other means must be devised for overcoming the difficulty. This is effected by running first from A to C, and then from C to B. Supposing C to be situated at a level of 300ft. above A, and A C to equal 140,000ft., the gradient from A to C and from C to B will be reduced to 1 in 46.6 and from C to B will be reduced to 1 in 46.6, which a locomotive can readily surmount. The engineering device of gaining height, by twisting the line as much as possible between any two levels, is familiar to all who are acquainted with the numerous railways in and about the suburbs of the metropolis. Common roads also afford abundance of examples.

Obviously, there is little or no danger in the reversing arrangement while the train is ascending, but the case is different when it is descending. Should the engine get beyond the control of the driver, or, in other words, run away, and overshoot the junction of the lines at C, the consequences must be of a most disastrous nature. Several fatal accidents of this description have occurred already in India, and the remedy does not appear very easy. There are three methods of pre-venting, or, at any rate, partially preventing the occurrence of such serious catastrophes. One would consist in prolonging the diagonal lines B C and C A to such a distance as would allow of the train being brought to In many instances, it would be absolutely impossible to accomplish this, and in all, from the peculiar nature of the very arrangement itself, it would be attended with great expense. Another method would consist in the crection of strong barriers at the points C and A, which, when properly furnished with buffers, would suffice to withstand the violent shock of the descending train, and bring it to a state of rest. Although such a course would be preferable to allowing the train to precipitate itself and contents down a precipice, yet it would constitute, after all, but a very rude and hazardous alternative. The only rival safeguard against such accidents is a large amount of brake

they would roll, and the barrier would have to stand the concussion. When it is borne in mind that many of these inclines in the ghauts are as sharp as 1 in 37, the velocity that a train would acquire in descending a distance of one mile can be readily imagined. That reversing points are an absolute necessity in carrying out steam locomotion in foreign countries, appears to be an established fact, but it is to be hoped that they will not be introduced wherever there is a single chance of avoiding them. They constitute an everlasting source of anxiety and danger, and in consequence of the accidents that have already occurred, means are being taken to abolish them in some of the situations where they were formerly deemed indispensable. Their danger was not fully understood until they were actually tried in practice, but now that the cost of human life has demonstrated the fact, the less use that is made of them the better.

#### THE DARIEN SHIP CANAL.

IN a short paragraph last week we briefly announced that the President of the United States had sent to the Senate, for ratification, a treaty which has been concluded with the Government of the United States of Colombia, respecting a ship canal across the Isthmus of Panama. This imacross the Isthmus of Panama. In Important circumstance has been brought about by General Caleb Cushing, to whom was entrusted the negotiation of the treaty, which grants extraordinary privileges for constructing the proposed work. By our last advices from America it appears that the full text of the treaty had not been prothe full text of the treaty had not been prothe full text of the treaty had not been promulgated up to Feb. 20, although the substance was known. From the American "Army and Navy Journal" we gather that the treaty grants the exclusive right to the United States to construct the canal anywhere between 4deg. and 18deg. north latitude. The Colombian government has aggred to give a large section of land on agreed to give a large section of land on either side of the route selected, and guarantees the perfect neutrality of the canal in time of war. This latter clause in the treaty was found most difficult to settle, and for a time interrupted the negotiations between Mr. Sullivan, the American Minister, and the Colombian authorities. Mr. Sullivan maintained that the right should be stipulated for Colombia and the United States to close the canal, in time of war, against the vessels of any nation with which either of them were at variance. Colombia was willing to agree to almost anything in order to secure the construction of the canal, but she was not quite ready to concede this point. If she did so, her statesmen argued, foreign nations other than the United States would make it the pretext for a quarrel, in which case she, being a weak nation, would receive all the blows, while the contesting nations would reap all the advantages. Mr. Sullivan insisting upon his point, the Colombian commissioners resigned, sometime in December, and thus brought the negotiations to an abrupt conclusion. General Cushing arrived abrupt conclusion. General Cushing arrived at Bogota on the 3rd of January last, specially commissioned by Sccretary Seward to conclude the treaty. A few days afterwards new Plenipotentiaries were appointed by the Colombian government, and the business was resumed with such energy, that in five days the terms of the treaty were settled, and a contract approved by the President. The neutrality clause, it appears, was adjusted in a manner which was considered fair to all parties concerned, and so arranged as not to give offence to European nations.

purpose, and which has capital waiting for treaty to be concluded. At the head of this band of capitalists stands the name of Commodore Vanderbilt, the remainder are gentlemen who, we understand, are amongst the foremost and most energetic capitalists in America. The question of connecting the Atlantic and Pacific Oceans has been mooted several times before the present. The undertaking, however, is of such gigantic proportions that, notwithstanding concessions quite as liberal as those now made have been offered before by the government of New Granada, none have been found equal to the task of even exploring, with any degree of success, for a route. The nearest step which was ever before taken towards constructing a canal was in 1853, when an English company was formed, with £15,000,000 capital, for the purpose of carrying into execution a plan of Dr. Edward Cullen, who had made some observations and assumed that, "if levels should prove as they were supposed to be, a canal capable of passing the largest vessels might be constructed from the bay of San Miguel, on the Pacific coast, to the bay of Caledonia, on the Atlantic."
The United States and Great Britain, by treaty, agreed to extend their protection to all parties engaged in the construction of the canal. After Dr. Cullen's plan had been thoroughly discussed, the English company determined to abandon it, and proposed to adopt one of the Nicaragua routes and build a canal of smaller dimensions. The United States government then withdrew its protection, which course was followed by a similar withdrawal on the part of Great Britain. The present project has formed the subject of no less than four previous characters are in the course of the less than four previous characters. of no less than four previous charters, which have been granted at various times by the government of New Granada and its successor, the United States of Colombia. One of these charters was granted in 1851; one in 1852; another, that to Dr. Cullen, in 1853; and a fourth, in 1855. These conceswere all made to private parties or sions corporations, as the governments avoided any alliances. The failure of private enterprise, however, has at last led to the conclusion of the treaty in question.

In constructing a canal across the Isthmus of Panama far greater engineering difficul-ties will have to be overcome than attended the construction of the Panama Railway, which was completed within five years. The length of that road is about 48 miles; its maximum gradient is 60 feet to the mile, and its summit level 259 feet above the sea level. To overcome such gradients locks will have to be constructed, and the main difficulty appears to be the finding of water for their supply. In 1843 two French engineers made examinations over the ridge of the Ahogaytequa, the highest point of which was two hundred and sixty feet above the sea. They could devise no other way of building the canal but by constructing a tunnel through the mountain, the level of which should be one hundred and thirty-five feet above tide, and the approach on the Atlantic side by eighteen locks, and on the Pacific side by being limited it was thought doubtful if any feasible system of reservoirs could be devised. We have at present no data upon which to found any further remarks upon the difficulties which must be overcome in building this canal. The Panama railroad route exhibits the one most easily surmounted, and even that may not be practicable for a canal. The plan of the French engineers, cited above, shows one of the chief difficulties in the way of the lock system—the insufficient supply of water. 'The gentlemen who have the undertaking in hand are men of experience in public enterprises; have doubt-less counted well the cost, and are prepared to execute this great undertaking even though they should be compelled to tunnel we wish every success.

the mountain at its base, or cross over it with locks, supplying the water to the reservoirs by artificial means. The great Central American Isthmus is, in fact, a chain of isthmuses, being formed of several necks, connecting large swells or lobes of extensive areas. Accordingly, we have the Isthmus of Panama at Panama; the Isthmus of Darien at the Atrato river; the Isthmus of Nicaragua at the lake of that name; the Isthmus of Honduras at the bay of that name; and the Isthmus of Tehuantepec at Tehuantepec. The general trend of the Pacific coast of Central America is northwest and southeast, but the Atlantic coast has a very irregular shore line. The Cordilleras, connecting the mountain systems of the country, lie near to and parallel with the Pacific coast. mountain system is the great obstacle to the construction of a canal. It may be easy enough to follow a river to its head in the mountains, but to cross in the ordinary way by a mountain summit level is almost impracticable, because there is no drainage basin or area available for supplying the high summit level with water, and the mountains could only be tunnelled at an elevation when the full-sized river could be diverted into the tunnel level.

We will not, however, meet these diffi-culties half way, but we will assume that they will be overcome by the engineering skill of our American friends, who have executed and are now carrying out works approaching in magnitude to those in question. By the completion of this canal, great advantages would accrue to America, and her commerce would make still more rapid strides than it at present is making. It is estimated that the saving in distance by the Isthmus canal will be as follows:-New York to Calcutta, 4,100 miles; to Canton, 8,900 miles; to Shanghai, 9,600 miles; to Melbourne, Australia, 3,340 miles; to Jeddo, Japan, 6,490 miles. Here is an immense saving in distance which is invaluable to commerce. Another point to be considered is that a canal would enable vessels to pass from ocean to ocean without breaking cargo. A smaller class of ships too could be employed in the carrying trade—vessels whose safety would be endangered by a passage round the Horn. It is estimated that the commerce around Cape Horn and over the Isthmus of Panama now amounts to about 3,500,000t ons annually, at an expense of, say, 10 dollars per ton, making a total of 35,000,000 dollars per year. Suppose half this expense should be saved by the construction of a canal, would not the enterprise pay, even if its building should absorb millions? The Panama Railway cost about 9,000,000 dollars, and nearly paid for itself in the first seven years. The road is now paying handsomely, and rewarding its shareholders with heavy dividends. The trade of England, France, and the United States, that would, in all probability, pass through the canal, has been estimated at 467,830,000 dollars, and as these figures were made up after careful study of the subject they may be deemed very nearly correct. It is estimated that the saving in money to the trade of the United States would be 36,000,000 dollars; to the trade of England, 9,958,000 dollars; to the trade of France, 2,180,000 dollars; and to the trade of the combined world, 49,500,000 dollars. Should the trade of the world increase in the same ratio—100 per cent.—for the next ten years, that it has for the past ten, there will accrue a saving of 100,000,000 dollars, when the canal is finished. These figures are of course only hypothetical, but enough has been said to show the importance of the scheme to the world in a commercial point of view, and to prove that a great saving would accrue to all nations from the construction of the canal. We shall watch with interest the progress of this great work, which we hope to see one day brought to a successful issue by our American friends, to whom

THE ROYAL INSTITUTION.

JUST before the beginning of the present century, Count Rumford, and a few other men of science, formed themselves into an association for the purpose of starting an institution devoted to philosophical research, and the popularization of science by means of lectures. A few houses in Albemarle-street were bought for the purpose, and in a short time the present Royal Institution building arose upon the site. The association was incorporated by a royal charter, and afterwards obtained further powers by an Act of Parliament. The opening proceedings at the Institution were characterized by great vigour, more than a dozen committees being appointed at the outset, to investigate different subjects, consisting principally of improvements in cooking and improvements in building. In fact, in those early days, the attempts of the managers were to promote the commercial applications of science, rather than to elucidate scientific laws; and the rules were so formed, that the shares in the Institution could be bought and sold in the market, and held forth prospects of commercial profit from the work done by the staff in Albemarlestreet. The constitution of the governing body was also partly hereditary in its nature, so that, as Sir Humphry Davy complained, people having no ability to take a share in the management possessed that power; wherefore, between the commercial and the hereditary principles, the Royal Institution was in a very few years brought to the verge of bankruptcy. Sir Humphry Davy then gave a lecture upon the difficulties into which the Institution had fallen, and told the members that they must either close the doors for ever, or abolish the hereditary feature in the management, cease the sale of shares, and allow the governing body to be elected by ballot, from the great body of the subscribers. The latter alternatives were adopted, and the Royal Institution fell gradually into the hands of members who took a warm and active interest in the promotion of physical science. At the present time, it is the best establishment in London for pleasing education in all branches of physical science, in lectures illustrated by good experiments, and given by scientific men of high ability. During the session, which lasts from January to June, day lectures are delivered from 3 to 4 o'clock, on Tuesdays, Thursdays, and Saturdays. There are also Friday evening lectures, to which members and their friends only are admitted. There is no doubt that intelligent children of twelve years of age and upwards would be benefited materially by being taken from school for six months, and allowed to attend lectures at the Royal Institution; such attendance also they might consider both a privilege and a holiday. More especially is such a course of value, because day by day the old plan of surfeiting children with dead languages is discovered to be bad, and more useful branches of education, such as physical science, are felt to be preferable. The Royal Institution is the scene of the labours of Davy, Faraday, Young, Brande, Frankland, and Tyndall. At the present time, the president of the Institution is Sir Henry Holland, Bart., M.D.; Dr. John Tyndall, F.R.S., is the professor of natural philosophy; Dr. William Odling holds the office of professor of chemistry; and Mr. Benjamin Vincent is the librarian. The library is a large one, and the reading room is well supplied with periodicals and newspapers. The lectures are delivered in a very papers. The lectures are delivered in a very commodious theatre, and the laboratories, in the lower part of the Institution building, are rich in philosophical experimental apparatus, which has been accumulating for the

past seventy years.

It being our intention to give, with tolerable regularity, notices of the work done at the Royal Institution, because it is a centre where all the sciences meet, we begin with the pro-ceedings of last week. On Tuesday, the Rev.

F. W. Farrar, M.A., F.R.S., lectured upon "Comparative Philology," and pointed out how nearly all the languages of Europe, and many of those of South-Western Asia, are derived from an extinct Aryan language, derived from an extinct Aryan language, once spoken by a people who lived probably to the north-east of India, near the banks of the Oxus. The Greek, the Sanscrit, the Latin, and the Keltic languages all sprung from this parent stock, and so, consequently, do the greater portion of the people who speak them. On Thursday, Dr. J. Harley lectured on "Respiration," and explained the general construction of the lungs, the heart, and the great disphragm which separates the lungs from the stomach below.

On Friday night, Mr. W. Huggins, F.R.S., lectured at the Royal Institution upon "The lectured at the Royal Institution upon "The Latest Discoveries in Astronomy made with the Spectrum." Sir Henry Holland, Bart., F.R.S., presided. The great theatre of the Institution was filled to overflowing, and among the listeners were Professor Tyndall, Admiral R. H. Manners, president of the Royal Astronomical Society; the Duke of Argyll; General Sabine, president of the Royal Society; Professor Frankland, F.R.S.; Professor W. Allen Miller, F.R.S.; and the Archbishop of York.

Archbishop of York.

Mr. Huggins said that the fact that messages recorded in the light of the stars many years ago can now be read by the aid of a glass prism, sounds more like romance than sober reality. A beam of light can be dis-sected and its different waves spread out in a band of brilliant colours for quiet examination, this band being what is known as "the spectrum." Spectra are of three types; all white hot solid or liquid bodies give in the spectroscope a brilliant unbroken rainbow band, or, in other words, a spectrum of the first order. Incandescent gases do not give a continuous spectrum, but a few bright vertical lines only. When an incandescent body is surrounded by a gas or vapour, a nearly continuous spectrum, cut vertically here and When an incandescent body there by a few hair-like black lines, is the result; and these lines, by their position, give information as to the gases by which they are produced. Thus, on examining the light coming from any fixed star by the aid of a telescopic object glass and a star spectroscope, the spectrum at once gives plenty of informa-as to the nature of the source of light, and further particulars may afterwards be obtained by measurement of the positions of the lines. After explaining that there are some conditions which modify the character of the spectra thrown by a few chemical substances, Mr. Huggins said that in some cases the spectrum is adapted to tell whether the luminous body is approaching to the observer, or receding from him. The stars, though receding from him. The stars, though apparently motionless, are not so in reality, and the motions of some of them which move transversely to the observer have been measured by good astronomical appliances. if the star be approaching or receding in the line of sight of the observer, its motion cannot be detected by measurements, nor by photometrical instruments, because many of the stars are variable, and an increase or decrease of brightness may not depend upon change of distance. To detect these motions, the spectrum has at last been found useful, for it is evident that if a star be moving towards the observer, more waves of light will be thrown into the spectroscope in a second than if the star were standing still; on the other hand, the receding motion of a star would cause a reduction in the number of waves entering the spectroscope in a given time. The effect of such motions is not to alter the colour of the star to the eye, but to slightly shift the positions of the lines in the spectrum. The shifted position of the chief hydrogen line in the star Sirius indicates that the star is receding from us at the rate of 41 miles per second; but as the observer was stationed upon the

from Sirius at the rate of 12 miles per second, this modification gives 29 miles per second as the rate of recession of Sirius. Measurements prove that it is almost certain that our sun, earth, planets, and solar system are moving from Sirius towards Hercules at a speed of 4 or 5 miles per second, and this further modification gives the amount of recession of Sirius from the earth as about 261 miles per second, as revealed by spectrum analysis. This true motion of Sirius is mixed, of course, with the transverse motion. The lecturer said that the nebulæ show mostly three bright lines like those from incandescent They probably contain nitrogen and gen. Comets give three bands of hydrogen. light, and appear to contain carbon as one of their constituents. Mr. Huggins closed by calling attention to his latest discovery of a method of seeing the solar prominences by direct vision without an eclipse. It being known, by observations of the last eclipse in India, what light is emitted by the prominences, Mr. Huggins searched for a coloured glass which would transmit the chief light emitted by the prominences, but cut off all other rays, so as to get rid of the excessive brightness of the limb of the sun as seen through the telescope. A spectrum was thrown upon the screen, and a piece of the red glass was interposed in the path of the rays, when it was seen that the glass cut off all the light except a narrow red band. With a piece of such glass in the telescope, the prominences may be seen with difficulty under favourable conditions.

On Saturday afternoon, Dr. William Odling, F.R.S., lectured for the eighth time, at the Royal Institution, upon "Hydrogen and its Analogues." One of the most striking of his experiments was an exhibition of the combustion of phosphuretted hydrogen in oxygen. Phosphuretted hydrogen is a very inflammable gas, which catches fire at once when it is exposed to air. Dr. Odling took a tall and very narrow glass jar, about 21 in. in diameter, and 18 in. long, and half filled it with oxygen over a glass pneumatic trough, full of water. A few bubbles of chlorine were then mixed with the oxygen. The great tube, half filled with oxygen, was then held firmly in the left hand, and, with the right hand, phosphuretted hydrogen, from an inverted test tube, was allowed to ascend one bubble at a time into the oxygen. Directly the bubble burst at the surface of the water, it united with the oxygen with a brilliant flash like lightning, at the same time giving the jar a violent shake. The experiment must be performed not many minutes after the chlorine has been added to the oxygen, otherwise two or three bubbles may enter the jar without catching fire, and then all go off at once with a dangerous explosion. For many reasons, it is not an experiment suited for those unskilled in chemical manipulations.

### STREET TRAMWAYS.

OF the twenty-eight schemes for railways, tramways, and other improvements or works connected with the metropolis, for which plans were deposited at the Private Bill Office, up to November 30 last, in accordance with standing orders, above half have already dropped out of existence from the failure of the promoters to make the necessary deposits. or other causes. In some instances, no bill has followed up the plan; in others, the House has refused to send the bills "upstairs," but has thrown them out on the motion for the second reading, without inquiry into the merits. The plans deposited included fifteen for railway works, four for street tramways, and nine for miscellaneous projects. Brighton and Metropolitan line of 46 miles was by far the most important of the railway bills; and, next to it, perhaps, the underground earth, which is a moving platform, an allowance line between Clapham and London Bridge. must be made. As the earth was moving Both of these were dropped at an early stage.

Of the tramway schemes, the most extensive was the system of which Mr. T. Page, C.E., was engineer—the Tramway Company—by which it was proposed to lay down above 60 miles of street tramway in London and the suburbs. The extent and the varied ramifi-cations of this scheme were probably a cause of its failure, the formalities to be observed in relation to tramway bills as regards county and parish notices, deposits of plans and bills, and other particulars, being of a very onerous character. From whatever cause, although the plans were duly deposited on November 30, copy of the bill was not forthcoming, as required, on December 23, and the scheme consequently fell through. The other three tramway schemes have been kept upon their legs to the present time; standing orders have been complied with, the bills have each been read a first and second time, and committed, which is a great point gained. three are—the Metropolitan, for about 16 miles on the north of the Thames; the Metropolitan Street, for about 19 miles on the south of the Thames; and the Pimlico, Peckham, and Greenwich, for about 7 miles, the greater portion, as the designation implies, also to the south of the Thames.

Last year, a tramway bill was granted for Liverpool, but none of the three bills for street tramways for the metropolis reached a second reading or committal. Two of the bills now committed, the Metropolitan and the Metropolitan Street, have been petitioned for in previous sessions; the third, the Pimlico, Peckham, and Greenwich, is a new bill. It is probable that the consideration of these bills in committee—the three are to be con sidered by one and the same committee—will excite more lively interest than the proceedings in relation to any other private bill of the session affecting London. It may be that the promoters have been more strenuous and persevering than on former occasions to excite interest and to conciliate support; if so, they have fair reason to be gratified by the success they have achieved. They have success they have achieved. appealed to local boards of works, to vestries, to open public meetings of ratepayers, and, to some extent, to the inhabitants of the districts chiefly interested, and, in almost every case, have obtained cordial promises of support, and large majorities. In some instances, indeed, the most lively interest has been manifested, and resolutions of support have been adopted unanimously with enthusiasm. In the debate in the House of Commons, a few days since, which resulted in a division, on the motion for the second reading of the Metropolitan Street Tramway Bill, the second reading was carried by a vote of 209 to 78. The motion was supported by Mr. Lefevre, the Parliamentary representa-tive of the Board of Trade, who announced, officially it may be presumed, that it was the wish of the Metropolitan Board of Works, and of the Board of Trade, that the bills should be referred to a select committee. Mr. Locke, the member for Southwark, would have thrown out the bills without inquiry into their merits, the most notable points in his speech being a sneer at the promoters as American "philanthropists," and a condemnation of the tramways laid down by Mr. G. F. Train some years since. The members of the House of Commons, and the public generally, have outlived this sort of thing, and are disgusted with such a puerile mode of dealing with an important question. Mr. Maguire, the member for Cork, applied the merited rebuke that we were indebted to private speculators, to the energy of capitalists, combined with the energy of the people, for many of our most important social undertakings, and such associations were not to be put down, or the public denied the beneficial results of their joint action, by a mere sneer

at projectors.

It is perfectly notorious to every one acquainted with the subject in the slightest degree, that no one proposes to lay down

Train's rails, or anything resembling them in form, or obnoxious to their radical defect of breaking the general level of the street. At the office of the Metropolitan Street Tramway Company, in Kennington Park-road, which is open to the public, there is quite a little museum of tramway models and samples. The patterns of rail include a short length of Train's rail, as actually used, a piece of the rail in use at Birkenhead, the rail sanctioned by the Corporation of Liverpool, and to be laid in the streets of that town, with several other modifications, all of which are essentially different from Train's rail in this respect, that they have each a groove on the face of the iron rail—so narrow, from 1in. to 1\frac{1}{2}in., that no ordinary wheel can get into it; whereas Train's rails really produced a groove on the road-way 4ft. 8in. wide, and in deep, which vehicles got into very easily, but could not get out of again. The one form of rail, presenting two continuous breaks in the level of smooth iron edges, exposed horses and vehicles to danger or damage in crossing, even at a right angle, but much more so in crossing obliquely. The rails now employed, crossing obliquely. The rails now employed, including the samples above referred to, can offer no obstruction to the passage over them, in any direction, of other vehicles or of horses; the grooves are too narrow to admit the wheel tyre of a lady's phæton, or to catch the cork of a pony's shoe. The approved Liverpool rail has an excellent feature in the corrugation of the portion of the surface of the rail to the inside of the groove. The rail is about 4in. broad in all, and has the groove, which is a little more than 1in. wide at the top, or widest part, near the centre. surface of the rail is smooth to the outside of the groove for traction, and corrugated on the inner side, to afford better foothold to horses crossing; the surface of smooth iron on the roadway is thus reduced to a minimum.

The particular form of rail to be adopted, and the materials to be employed in the construction and maintenance of the tramway between the rails, and a belt of 18in. on each side, which the bill provides shall be done at the expense of the companies, will be subject, of course, to the approval of the Metropolitan Board of Works and the Board of Trade. Granite sets, between the rails and on each side of them, will probably be preferred, as best fitted to secure good working condition in the rails, to avoid the formation of ruts, and to prove most economical in the long run, although involving a much heavier first cost than the ordinary rough metal. There is no reason to fear that any mechanical difficulty will be met with, either as regards the form of rail, or in other respects, to prevent the perfectly safe and successful working of the system. It was well and cogently remarked by Mr. Whitbread to the House of Commons, in the debate referred to, that it was no reacon that because a bad system failed ten years ago, a good system should not be tried now, We venture to think with Mr. and succeed. M'Arthur, the member for Lambeth, who has experienced the comfort and convenience of the street railway cars in the crowded thoroughfares in New York, that if street railways were once fairly introduced in this metropolis, such advantages would result that everybody would oppose the idea of their discontinuance. Mr. Laird, too, the member for Birkenhead, bore his "emphatic testimony" to the value of tramways in the town he represents, where they run from the ferry to the very heart of the town, as also the six miles along the Liverpool Docks, without the slightest inconvenience to the general traffic. It is to be hoped that a mode of street loco motion, which has proved of signal public advantage in all the great cities of the United States of America and of Canada, and which is so highly appreciated at Birkenhead, that a boon, granted last year to Liverpool, Virtue and Co., 26, Ivy-lane. 1869.

will not be longer denied to London, for no better reasons than the vague supposition that tramways will answer in almost any thoroughfares in the world excepting the suburbs of London, and that the London General Omnibus Company "have taken measures to oppose the scheme."

#### TELEGRAPHIC LITERATURE.

T is some little time since Mr. Sabine published his for ball lished his first book on "The History and Progress of the Electric Telegraph." The edition which then appeared consisted of two parts—the history of the electric telegraph, and its science and practice. The work met with a great deal of attention, and a vast amount of new and useful matter was brought out in the second part. "It has now," according to the author's preface, been decided to separate these parts into distinct volumes, it being thought that there are many who, whilst interested in the history and apparatus, may not care for the scientific part; whilst others, and especially those connected with telegraph engineering, may find only the information collected in the second part useful to them. For carrying out these objects there could be no better channel than 'Weale's Rudimentary Series,' the high character of which has rendered it deservedly celebrated." We cordially endorse the author's remarks, and feel glad to see some really good works on telegraphy added to the few that have already appeared in this series. The object of the present book\* is to give an account of the gradual rise and progress of electric telegraphy from the earliest known date down to the present time, including accounts of the various discoveries and inventions that have principally tended to produce the great results we are every day in the habit of witnessing.

In tracing the early history of telegraphy. very interesting fact has come to light respecting the peculiar knowledge Galileo had of magnetic action; and in one of his dialogues, written in 1632, the following conversation takes place (the discovery of this fact is due to Mr. Richard Bellamy, who called the author's attention to it, and to whom, also, we are indebted for the translation), "You bring to my recollection a pertion), "You bring to my recollection a person who offered for sale to me a scientific secret, which, through a certain sympathy, and a magnetic needle, enabled two persons to discourse with each other at a distance of two or three thousand miles. And when I told him that I would gladly purchase it, provided I first had a proof of his art, and that it would suffice for the matter if I placed myself in one corner and he in another corner of the room, he answered that it was scarcely possible to discern the operation in so small a distance Wherefore I sent the man away, and said that at that time it was not convenient for me to go to Egypt or Muscovy for the sake of trying the experiment; if, however, he was willing to go there, I would undertake the other parts, remaining in Venice." There are several instances in the early writers of sympathetic telegraphy, but it appears that this is the only one where there is something really tangible as to the modus operandi. Bellamy deserves our best thanks for bringing to light so interesting a conversation bearing on the early history of telegraphy.

The following are the principal points in this work—early observations on electrical phenomena, telegraphs by frictional and voltaic electricity, and by electro-magnetism and magneto-electricity. An excellent and most useful description is given of the various telegraphs now in use. Treating of con-

struction, we find a large amount of information on overhead and submarine and underground lines; and the final chapter is given to atmospheric electricity. We feel sure that this edition, containing so much and such useful matter to the practical telegraphist, will be welcomed by all engaged in the profession as a most useful addition to their

telegraphic library. We turn next to a brochure on telegraph companies as investments,\* the author of which justly considers that they have not. up to the present time, met with that support that their prosperity and merits deserve. His remarks are, however, principally applied to submarine cables as an investment, and in proof of the policy of laying out one's money in such concerns, he points out, and enters into, some details of the Anglo-American Telegraph Company, with their property of two Transatlantic cables. There is much in this portion of the brockure that all who are acquainted with telegraph matters must recognize as being correct, but the want of confidence subsequently shown by the public to submarine enterprise must not, as he apparently does, be set down to a want of confidence in cables themselves, but due entirely to a want of confidence in anything

—a result perfectly natural after the fearful panic of 1866. The successful operations connected with the Atlantic cable in 1866, and the two successful repairs in 1867, have acted most favourably towards submarine cables, and the result is now evident—the money panic having worn off—in the eager way in which submarine telegraph companies are generally invested in. A comparison is made between submarine lines and land lines, in the annual amount of maintenance that they respectively cost, very much to the advantage of cables; but the author, probably from a want of engineering knowledge of the subject (which may be several times subject (which may be several times noticed) forgets that the annual sums expended on the maintenance and renewal of land lines keeps that property always at its full value; whilst the maintenance of a cable consists only of repairing any accident that may happen, the expenditure on that account only restoring to good condition the part specially affected, whilst the whole property is gradually and surely depreciating.

With regard to East India communication, the author proposes the one remedy of having a submarine line from Land's End to Bombay, via Gibraltar, Malta, Alexandria, and Suez. "The only thing wanting in this wonderful (sic) scheme is the money to carry it out." We quite agree. But while recommending this scheme, he does so at the expense of the Persian Gulf route, which is characterized as "almost useless" (although communication with India has well and satisfactorily been carried on by means of this route for several years), and also of the proposed line from Suez to Bombay. But, unfortunately, the author quite forgets that the arguments he appears to think so strong against the line from Bombay to Suez are stronger against the proposed scheme. There is much in the subject that requires attention, and we are surprised that submarine telegraph shares are not more in request; but we feel sure that any new telegraph scheme will succeed far more on its own individual merits than by the attempt of running down projects that are, and indubitably will be, of advantage.

#### PARLIAMENTARY NOTES.

N the House of Commons, on Thursday week, Mr. W. EGERTON asked the Secretary of State for the Home Department when the report of the commissioner appointed to inquire into the opera-

<sup>&</sup>quot;Telegraph Companies Considered as Investments; h remarks on the Superior Advantages of Submarine with remarks on the Superior Advantages of St. Cablea." By J. WAGSTAFF BLUNDERL, Public Ac London: Effingham Wilson, Boyal Exchange.

tion of the Bleachworks and Printworks Act, which was promised at the end of last session, would be laid upon the table, and whether he intended to bring in any bill on the subject during the present session.

Mr. Secretary BRUCE replied that the commissioner had unfortunately been ill, or the report would have been presented. The commissioner, however, was now busily engaged upon his report, and, should there be time to do so this session, he (Mr. Bruce) hoped to embody some of the recommendations in a bill.

On the same evening, Mr. S. HARDY asked the First Lord of the Admiralty whether the reductions contemplated in the coast-guard ashore were to be general throughout the kingdom or confined to particular stations; and, if the latter, whether he would object to name the stations affected by

Mr. CHILDERS said that the reductions were shown in the estimates for 1869-70. The number of the coast-guard on shore at present was 4,850, and it was proposed to reduce that number to 4,625, or by 225 men, of whom 50 were civilians and 175 seamen. The reduction would be over the whole service, and the average reduction would be four at each station.

MR. WHITE asked the First Lord of the Treasury whether, after the recent declaration of the Secre tary of State for War, that "it would be very unfortunate if the patronage connected with the army were transferred from the Field Marshal Com manding in Chief to a political officer," it was the intention of her Majesty's government to revive the office of Lord High Admiral, and transfer to him the naval patronage now vested in the First Lord of the Admiralty.

MR. GLADSTONE, - Sir, my hon. friend has framed a proposition of four terms. He thinks that as the Secretary of State for War is to the Field Marshal Commanding in Chief, so is the First Lord of the Admiralty to the Lord High Admiral. I apprehend. however, that that is not the fact. The Lord High Admiral is a great officer of state, who, according to the ancient arrangements of the country, was charged not only with the patronage, but with the whole of the administration of the navy. The First Lord of the Admiralty is simply the firstnamed member of a commission to whom is now entrusted the duties of the Lord High Admiral, precisely as the duties of the Lord High Treasurer are entrusted to the commissioners of the Treasury. I do not, sir, propose to revive the office of Lord High Admiral. The statement was received with

some merriment by the House.

The most important event of the present week was the moving the estimates for the navy by Mr. Childers, on Monday night. The House having gone into a committee of supply, Mr. Childers commenced his remarks by reminding the House that the Speech from the Throne, at the opening of the session, had referred to certain reductions of naval expenditure, the right hon. gentleman stated that upon a comparison of the estimates for the year 1869-70, with those for the current year, the former showed a reduction in round numbers of £1,100,000, and compared with the previous year of £1.300, 000; and this reduction was distributed pretty fairly all over the votes. He then passed on to the subject of the governing body at the Admiralty, observing that it was not intended to make any change in its constitution, but to carry out the objects of the commission of 1860-61. The first Sea Lord of the Admiralty, therefore, would take charge of all business connected with the personnel of the navy; the Controller of the Navy would take charge of all the business connected with the materials of the navy, the dockyards, and the purchase of stores; and both those great officers would be directly responsible to the First Lord without the intervention of either board or commission. Another arrangement was to get rid of the division now existing between Whitehall and Somerset House; and in effecting the union of these establishments at Whitehall, he had done his best to act kindly and tenderly towards the civil service; so that, up to this time, he did not be that any injustice whatever had been done. Those who had been discharged were placed upon a redundant list, and so long as any efficient persons remained on that list, the vacancies occurring in the service would be supplied from it. Time had the service would be supplied from it. Time had not yet admitted of his taking up in detail the administration of the several dockyards; and all he had been able to do was to effect some minor

changes in respect of the number of officers and the business of the yards. It was proposed, however, to carry out a unity of management as far as possible. Instead of having the constructor of the navy and the head of the steam department two co-ordinate departments, they would be brought into one focus; so also would the master shipwright and the engineer, and this had already been done at Chatham and Portsmouth. The dockyards at Woolwich and Deptford would be closed on the 1st of October next, the Government being of opinion that they were not required. He was desirous, without delay, to utilize the ground, machinery, and plant at Woolwich by employing them as private establishments, if persons could be found to take them; but it would be disadvantageous to sell them at present.

Mr. Childers then went into the question of Mr. Childers then went into the question of the policy of the Government with respect to our fleets and men. He observed that at present we had 80 ships manned by 11,767 men on the southeast coast of America, the Pacific, the Australian, and China Seas, and on the west coast of Africa; and those would be reduced to 64 ships and 8,500 men. Three ships would be taken off the west coast of Africa alone, and India would have to bear her share of her naval protection. No final decision had yet been come to as to the Medidecision had yet been come to as to the Medi-terranean and North American fleets. The policy of the late Admiralty of sending out a flying squadron to visit the several foreign stations would squaron to visit the several foreign stations would be acted upon, he hoped, early in the spring; and a reserve squadron would be formed, to consist of four ironclads, four line-of-battle ships, and the Mersey frigate. In the Naval Reserve the only changes made were in the details, but in the cours of the year it would be advisable that the Admiralty and the Board of Trade should institute a departmental inquiry into the whole of the arrangements connected with that branch of the service. The number of men he proposed to ask for was 63,300, as against 66,770 the previous year; but he confessed that he could not take credit for the whole of this reduction, the greater portion of it having been effected by his predecessor, Mr. Corry. The reduction would be entirely in the non-seamen. It was not intended to have a single blue jacket less, but to retain the number which he found on the but to retain the number which he found on the books when he assumed office. He proposed, however, to reduce the half-pay list of officers, especially of captains, commanders, and lieutenants, in a practical way. With this object a bill would be brought in for compounding with such of these gentlemen as could be spared, and paying them a lump sum in lieu of half-pay. This could be accomplished without the smallest loss to the country: the half-pay would continue to be voted, but it would be paid over to the Commissioners for the Reduction of the National Debt, and they would compound with the officers.

Next, with regard to the ship building and manu-

Next, with regard to the ship building and manurest, with regard to the snip building and manufacturing departments, the right hon, gentleman said he should minimise repairs and alterations. The period for which ships were commissioned would be increased from three or four years to five years, the effect of which would be greatly to five years, the effect of which would be greatly to reduce the expenditure. It was also intended to overhaul the stocks and stores in all parts of the world, and to re-cast the existing establishments. The dockyards would be maintained up to the point of efficiency, the reductions there being made gradually. Private yards would be resorted to as an adjunct, and the Naval Stores Act, which forbade the sale of old materials, would be repealed.

Upon the subject of new ships Mr. Childers stated that it was proposed to build at Chatham and Pembroke, at the beginning of the next financial year, two fixed turret ships which would be the most powerful in the world. A third ship, with a revolving turret, would also be constructed, and be

the most powerful in the world. A third ship, with a revolving turret, would also be constructed, and be an improved "Hotspur." When all the arrangements contemplated had been effected, our navy would consist of \$6\$ broadside armour ships, carrying \$25\$ guns; eleven turret and special ships, carrying 43 guns; 66 efficient unarmoured ships, and a considerable number of old ships; and no other naval power had a force that could compete with this fleet. In conclusion, the right hon, gentleman expressed a confident opinion that the several arrangements made and contemplated would work for the benefit a connect opinion that the several arrangements made and contemplated would work for the benefit of the public service, and moved a vote of 63,300 men and boys for the sea and coast-guard service for the year ending March, 1870, inclusive of 14,000 Marines

At the conclusion of this speech, which was of great length, Mr. Corry minutely criticised the exposition of Admiralty changes and reforms, observed that he had not intended to lay down any more armour-plated ships until the result of the experi-ments now in progress had been ascertained. He denied that the late Government had proposed a permanent increase in the navy estimates, and enumerated the reductions which he himself hoped office, and He to have accomplished had he remained in office which would have amounted to £658,000. objected to the proposed diminution in the number of coast-guardsmen and stokers, and expressed his apprehension lest many of the reforms had been Philosophical Society.

hastily made, and would not prove advantageous to the public service. As to the new turret ships, he would never have entertained the idea of building sea-going ships without masts, and unless the project were postponed until after the trial between the "Minotaur" and "Captain" had come off, he should divide the House on the vote.

A considerable amount of discussion followed Mr. Corry's remarks, and ultimately the vote was agreed

ON MICROSCOPICAL EXAMINATION OF DUST.\*

BY MR. J. B. DANCER, F.R.A.S.

THE author stated that he had made some mi-croscopical examinations of dust collected in L croscopical examinations of dust collected in June, July, and August last, and also of the particles contained in the rain water after the long drought. He had intended to bring these observations before the Society in a complete form, but had not hitherto found time to do so. He proposed to carry on observations during every month in the year, for the purpose of recording the average amount of solid matter deposited in a given area, and also as far as possible to ascertain the character of the deposits. The observations so far had shown, as might have been expected, that the dust in various localities, at different altitudes, and under other varying conditions, contained particles differing in magnitude, appearance, and quantity for the same superficial area. In every instance, molecular activity was abundant, but the animal life was very variable in amount, the largest number of moving organisms being in the dust collected at the lowest points; this was about 5ft. above the surface of the earth. This dust also contained the largest proportion in magnitude and quantity of vegetable matter. These observations also showed that in thoroughfares where there were many animals engaged in the traffic, the majority of the light dust which when disturbed reached the average height of 5ft., or about the level of a foot passenger's mouth, consisted of a large proportion of vegetable matter which had passed through the stomachs of animals, or which had suffered partial decomposition in some way or other. That was not an agreeable piece of informa-tion, but it was a fact. It showed the necessity, in a sanitary point of view, of the streets being well watered before the scavengers were allowed to commence operations; otherwise the light dust was only made to change its locality, and was not properly removed. It was not pleasant to contemplate the possibility of germs of disease being wafted along with that decaying matter, and inhaled by those whose condition might be favourable for its development. The author hoped to bring the details of the observations before the Society at some future time.

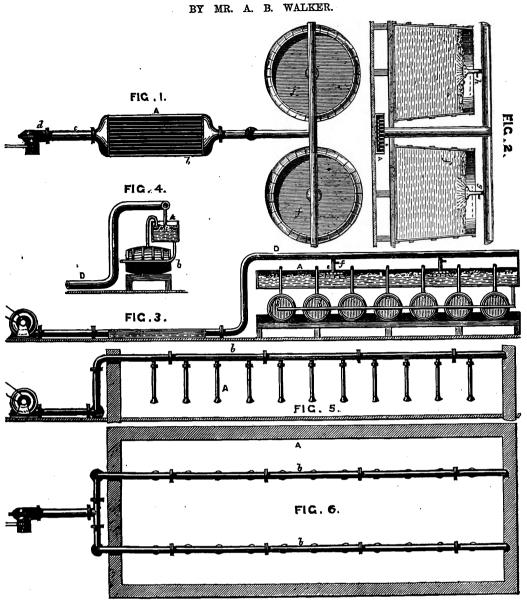

#### BULLION AND SPECIE.

THE value of gold and silver bullion and specie imported in the year 1999 THE value of gold and silver bullion and specie imported in the year 1868 was £24,852,595, against £23,821,047 in the previous year. Of the total value imported last year £17,136,177 is returned under the head of gold, the chief portion of which was received from Australia, £6,989,594; United States, £6,976,455; and Mexico, South America (except Brazil), and West Indies, £1,252,816. The imports of silver bullion and specie in 1868 amounted to £7,716,418, of which £3,203,972 was received from Mexico, South America (except Brazil), and West Indies, £1,915,939 from the United States, and £1,045,317 from France. The value of gold and £1,045,317 from France. The value of gold and 14,327,289 in 1867. Of the total value exported last year £12,708,308 is registered as gold, the chief portion of which was sent to the following countries, viz., to France, £7,189,646; Egypt, 1,497,826; Hanse Towns, 1,094,311; and Brazil, 1,018,240. The exports of silver bullion and specie in 1868 amounted to £7,511,706, of which £1,855,253 was sent to Holland, £1,821,748 to France, £1,489,165 to Egypt; £903,669 to Hanse Towns; and £843,235 to Belgium.

THE forty-seventh annual meeting of the Printers' Pension, Almshouse and Orphan Asylum Corpora-tion was held on Monday at the London Tavern, under the presidency of Mr. W. Rivington. After under the presidency of Mr. W. Rivington. After the adoption of the report, a resolution was proposed, and duly carried, sanctioning the transfer of the en-gagements of the Printers' Orphan Asylum and the Printers' Almshouse Society to the above corpora-tion. The appointment of officers was then pro-ceeded with, and the meeting concluded by a vote of thanks to the chairman. thanks to the chairman.

## WALKER'S ATMOSPHERIC TUN-ROOM ATTEMPERATOR.

WALKER'S ATMOSPHERIC TUN-ROOM ATTEMPERATOR.

Our readers do not require to be reminded that at no stage in the manufacture of beer is more vigilant care needed than at the fermentation of the wort. They are also fully aware of the value of a low temperature for producing a healthy and vigorous fermentation and for the preservation of the yeast. To secure this advantage, even in the hottest weather, has been the aim of Mr. A. B. Walker, brewer, of Warrington, and he realized his ideas in the atmospheric tun-room attemperator illustrated in the accompanying engraving. By this apparatus that portion of the atmosphere directly over the worts in a state of fermentation in the gyle tuns is attemperated, in summer or in winter, to that degree of temperature at which the process of vinous fermentation is most successfully conducted. In our engraving, figures 1 and 2 illustrate the application of the attemperator, a being the attemperator, which is a rectangular frame carrying a series of tubes b, placed about 5 in. apart. Ice, or any other cooling substance or freezing mixture, is placed in the spaces between the tubes, which are connected at one end by the pipe c, to the fan d. At the other end of the casing the tubes communicate with the pipe e, which is carried to the fermenting tuns ff. From each of the branch tubes over the tuns is a vertical tube g (fig. 2), ending in a rose, through the perforations in which the air makes its exit. The supply of air is regulated by the slide h, so as to suit the progress of fermentation. The fan is set in motion as soon as fermentation commences, and a cool stream of air is playing over the surface of the wort until fermenfermentation. The fan is set in motion as soon as fermentation commences, and a cool stream of air is playing over the surface of the wort until fermentation is complete. In very cold weather the freezing mixture is generally found to be unnecessary, the air from the fan alone sufficing for a healthy fermentation. Mr. Walker's experience is, that since the adoption of the attemperator he has never had any languid or sluggish fermentations.

To preserve the yeast in the trough during the process of cleansing, Mr. Walker adopts the system illustrated in figs. 3 and 4 of our engraving. The yeast passes into the trough or receiver a from the puncheons b b; a tube d is in connection with the attemperator, and from which the air is distributed over the surface of the yeast by means of the pipes s, the supply being regulated by the valve f. By this means, Mr. Walker finds vigour and vivacity imparted to the yeast, which is thus properly preserved.

This principle of attemperation has been applied to the manufacture of malt, so that it may be made in summer as well as in winter with equally good results. To this end the arrangement shown in figs. 5 and 6 is proposed by Mr. Walker: a is the malting room through which the pipes b b are led from the attemperator, at the height of a few feet above the floor level. To these pipes are attached the vertical flexible tubes c c, which are fitted with rose perforated caps, through which the cool air is distributed over the surface of the malt on the floor. It will thus be seen that Mr. Walker effects three very important improvements in the brewing processes, by the aid of of apparatus as simple as it is ingenious, and which will doubtless come into use wherever its merits are known. We may add that this apparatus is now being manufactured by Messrs. Morton and Wilson, of Alliance Chambers, Borough, London, and Stockton-on-Tees.—"Brewers' Journal." This principle of attemperation has been applied

#### COAL AND IRON ON THE CONTINENT.

THE iron trade displays more or less activity in all the French metallurgical groups. In the south of the Moselle, for instance, there are now orders on hand for some months in advance, while they still continue to arrive; since the summer, prices have advanced in this district 12s. per ton. The Terre Noire Company has obtained an order for 2,000 tons of Bessemer steel rails at £18 11s. 10d. per ton

delivered at Gray, and another for 6,000 tons at £13 14s. 3d. per ton delivered at La Chapelle. The Northern of France Railway Company has given out an order for 14,000 tons of iron rails to the house of Wendel at £7 16s. per ton delivered at Laon, and another order for 6,000 tons of iron rails to the Denain and Anzin Company at £7 16s. 10d. per ton at the works. The demand for pig is active in Prussia, and there do not appear to be in any district any considerable stocks; the price of pig has not experienced any material change in Prussia, but merchants' iron shows a continually upward tendency. The Belgian coal trade presents rather less animation; in the Charleroi district, however, the demand for coal for industrial purposes is well maintained. The Belgian iron trade continues firm, and an advance is even contemplated in some descriptions of iron. A Belgian house has secured an order for ten locomotives on Russian account. The production of coal in France in 1865 is estimated at 12,600,000 tons. In 1859 the corresponding production was only 7,681,000 tons.

THE MANUFACTURE OF WATCHES AND CLOCKS,—A most interesting and instructive little work, describing briefly, but with great clearness, the rise and progress of watch and clock making, has just been published by Mr. J. W. Benson, of 25, Old Bond-street, 99, Westbourne-grove, and the City Steam Factory, 58 and 60, Ludgate-hill. The book, which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices, and no one should make a purchase without visiting the above establishments or consulting this truly valuable work. By its aid persons residing in any part of the United Kingdom, India, or the Colonies, are enabled to select for themselves the watch best adapted for their use, and have it sent to them with perfect safety. Mr. Benson, who holds the appointment to the Prince of Wales, sends this pamphlet to any address on receipt of two postage stangs, and we cannot too strongly recommend it to the notice of the intending purchaser.—| ADVI. |

ELECTRIC TELEGRAPHY IRRESPECTIVE TELEGRAPHIC APPARATUS.

By Mr. E. G. BARTHOLOMEW.

(Continued from page 175.)

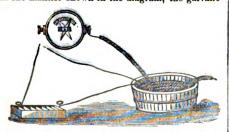

THE remarkable facts which have developed themselves in connection with submarine telegraphy, and which render it so interesting and important a branch of the subject, were first observed in connection with subterranean wires. In or about the year 1854, it was noticed that upon attempting to send a current through two wellinsulated buried wires between London and Manchester, the ends of which were united at Manchester, that an appreciable space of time elapsed between the transmission of the current into the one wire and its appearance at the other wire, provided the earth formed part of the circuit. That electricity should occupy an appreciable period in traversing 400 miles was a new fact; and, indeed, when two suspended or open wires of the same length were united in the same way, the time occupied in the passage of the current was, to all appearance, momentary; it could not there-fore be the distance which caused the delay. Again, if the buried wires were joined up so as to form a circuit wholly metallic, the earth being excluded, the same retardation did not occur.

The discovery of this fact, its evident importance in connection with submarine telegraphy, the imperfect state of our knowledge of the laws which govern the phenomenon, a consideration of the immense value of submarine lines of communication when completed, and the great pecuniary losses which had been incurred in futile attempts to lay cables up to 1861, was an ample justification for the appointment of a Royal Commission in that and the previous year to investigate the entire subject. Out of 11,364 miles of cable submerged up to that period, but little more than 3,000 miles

were in working order, or earning a revenue.

The same laws of R hold good with respect to submerged conductors as with suspended and it is not therefore necessary to repeat them here. Indeed, the law of induction also applies equally in each case, but the conditions necessary to its full development exist in so feeble a degree in the case of suspended wires, that it is not to be wondered at that the effects of induction in connection with telegraphy should altogether have escaped notice when no other form of telegraph existed.

It may be necessary to offer a few words of explanation upon this point. If a wire, covered throughout its entire length with an insulating material—say, gutta-percha—be suspended upon insulators in the same mauner as an ordinary open wire, it will present, upon the application of a battery pole, no features differing from those which an open wire would manifest under like conditions; but if the same covered wire be laid in water or moist earth, it is found that when the battery is applied in the manner shown in the diagram, the galvano-

meter will indicate that a momentary rush of electricity passes into the wire. This rush is electricity passes into the wire. This rush is called the "charge," and the wire is then said to be "charged." If the battery be now withdrawn, and an earth wire put in its place, the galvanometer indicates that another rush of electricity passes out of the wire into the earth. This second effect is called the "discharge." Now as no such phenomenon occurs when the insulating wrapper of the conductor is itself insulated, the inference is that the charge and discharge are dependent upon the combination of just two conditions—namely, that the wire shall be insulated, and the insulator not insulated. In another point of view we have the insulator—the dielectric—placed between two conductors, and in this lies the secret of the phenomenon.

A somewhat more familiar illustration will perhaps assist to make the point clear. If a common Leyden jar or a sheet of glass be coated upon each side within a short distance of its edge with metal foil, and a battery of high tension be applied, one pole to one side, and the other pole to the opposite side, the two surfaces of the glass acquire the same

tension as the battery poles, which the metal coating quickly distributes over the area it covers, and as the intervening glass is an exceedingly bad conductor-that is, interposes immense R sage of the current both over it and through itthese surfaces will retain their respective electrical states even after the battery is withdrawn, until connected together by a better conductor; and when they are so connected, the discharge of this tension passes through the conductor and becomes manifest upon a galvanometer placed in its circuit, the amount of the swing produced upon the needle indicating the amount of discharge. The amount of charge can be ascertained by inserting the galvanometer in the circuit of one of the battery poles. The proof that the charge is an effect entirely distinct from the constant flow of the current caused by any leakage in the dielectric is, that as soon as the surface is charged, the galvanometer needle will return to zero, although the battery contact is maintained.

It has been found by experiment that different dielectrics will take different amounts of charge and discharge; this amount is termed the "specific inductive capacity." It has also been "specific inductive capacity." It has also been found that the thickness of the dielectric has an influence upon the amount of induction.

To return to this subject as it affects cables, it will now be easy to trace the analogy. The copper wire is one conducting surface, the water or moist earth is the other, and the insulating wrapper is the dielectric. The surfaces of the conductors may be represented respectively in terms of the diameters of the copper and of the dielectric, and, combining all these conditions, we obtain the following formula, which represents the capacity of a unit of length of submerged and insulated conductor for charge, this being called its "electro-static capacity":

$$\frac{I}{2 \log \frac{D^{1}}{D}}$$

in which I is the specific inductive capacity of the dielectric, D, its diameter, and D the diameter of the conductor. It is obvious, however, that as surface has so much to do with the absolute capacity of a cable, the length of the conductor will exercise a material influence upon the actual amount of charge. This is gained by multiplying the result by the length.

It is natural to inquire what importance is to be attached to the amount of charge and discharge which a cable is capable of giving. The reply will be seen at once from the fact, that upon it depends the speed at which a cable is capable of transmitting signals—its speaking capacity. However large may be the electro-static capacity of a cable, the whole of the charge and discharge which enters and leaves must enter and leave it through the section of the conductor, and both these operations, when the charge is great, occupies an appreciable time. It would seem from this that by diminishing the resistance of the conductor, giving, that is to say, greater facility for the escape of the charge, you would diminish the time occupied. This is true, however, only up to a certain limit, for it must be remembered that by increasing the diameter of the conductor, you also increase its surface, and that in a higher ratio than the resistance diminishes. A reference to the formula shows that as D increases in value, the entire expression increases also.

The rate at which a cable can charge and dis-The rate at which a cable can charge and dis-charge itself is proportioned to the square of the length, other things being equal; and the speed of charging and discharging is, after all, only another mode of expressing the speed of working, because, before a second signal can enter the cable to be effective at the farther extremity, the first must be got rid of, unless every signal, and every interval between a signal, be exactly equal in duration; but as in practice this is unattainable duration; but as in practice this is unattainable, it is of the utmost importance that every means should be adopted to reduce the induction. startling, A single mile of No. 16 gauge wire presents a surface of 85.95 square feet, but even this does not represent the extent of inductive surface; and such a wire in a cables 1,000 miles in length contains almost exactly two acres of surface. Each of the present working Atlantic cables contains an area of conducting surface exceeding eight acres.

A consideration of the various dielectrics which

have been employed in the construction of submarine cables, either experimentally or in actual practice, will prove both interesting and

instructive. A large number of substance submitted to the Committee of Investigation of 1860-61, and a very careful and prolonged series of experiments were conducted, in order to of experiments were conducted, in order to ascertain their merits and demerits. whole of them, however, contained either guttapercha or india-rubber, either pure or in combination with some other material.

They were all subjected to the following tests:-Inductive capacity.

Insulation under changes of temperature.
Insulation under water pressure.

Absorption of water.

Effect of daylight.

Effect of exposure to the atmosphere.

The result of these experiments may be briefly

summed up as follows :-

The inductive capacity of caoutchouc is less than that of gutta-percha in the proportion of 8 to 10; its insulation or specific R is more than twenty times greater; it absorbs more water superficially, but the penetration of the water is not considerable. Both caoutchouc and guttapercha absorb from three to five times less seawater than fresh, and the salter the water the less it absorbs. The insulation of gutta-percha decreases under increased temperature much quicker than caoutchouc.

The quality of gutta-percha for telegraphic purposes has been greatly improved within the last few years. Its specific R has been nearly doubled since 1864, and the author has seen guttapercha which had been submerged in water at 100deg. Fah. exhibiting but little diminution of R.

In the construction of a submarine cable it is desirable, after having decided upon the core, to make the outer portion—the protecting covering of such a low specific gravity compared with its longitudinal strength, as that the completed cable shall be capable of supporting a very large excess of its own weight, when submerged in the deepest soundings in the proposed line of route. The wisdom of this precaution will be seen, when it is remembered that it is not always possible to lay a cable unintermittently. Many causes may and do continually arise for necessitating the stopping of the paying out, and when this occurs, the cable has sometimes to do the double duty of bearing all the strain due to its own weight, and also to hold on the ship. But more than this: if a fault has gone overboard, it is imperative not only to cease paying out, but actually to haul in perhaps some miles of what is already submerged. Every one knows or can understand the difference of strain upon a cable when being hauled in, and when being payed out. The narrative of the laying of the Atlantic cable of 1865 is worth the perusal of all who take any interest whatever in these matters. It will be found to contain much that is instructive as well as deeply interesting. (See "Macmillan's Magazine," for September, 1865.) The last two Atlantic cables—those of 1865-66, combined the essential characteristics of low specific gravity and high breaking strain in an eminent degree. The deepest soundings between Ireland and Newfoundland do not exceed 2,400 fathoms, or less than 21 nautical miles, yet these cables were calculated to bear eleven miles of their own length in water.

A comparison of the principal features in the old and new Atlantic cables may be instructive:

## ANGULAR RADIAL DRILLING: MACHINE.

BY MR. B. MILLER.

### EQUILIBRIUM SLIDE VALVE.

BY MR. J. E. OUTRIDGE.

In a few unimportant respects, the cable of 1866 differed from that of the previous year; its specific gravity was somewhat higher, but this was compensated for by its increased breaking strain. The advantages in the employment of a stranded conductor over a solid wire, when the metal employed is one to which a high test for longitudinal strength cannot be applied, as is the case with copper, is very apparent. If in a single wire a fault occur, or a bad joint be made, complete loss of continuity results from its yielding, whereas in a strand, care being taken that the several wires are never joined at the same spot, if any one wire gives way, others remain effective.

#### ANGULAR RADIAL DRILLING MACHINE.

THE machine illustrated in the annexed engraving, designed by Mr. Benjamin Miller, Sheaf Works, Leeds, is capable of drilling holes at any point on the surface of a hemisphere, as well as vertically and horizontally. The base consists of a hollow casting 7ft. by 3ft. by 2ft. 6in., provided with T-grooves and slot holes on its two sides and end for fixing the brackets or objects to be operated upon; it also carries a table with a transverse and longitudinal motion accomplished by screws; the taper is provided with T-grooves and slot holes on its top similar to the sides and ends. To the back end of the base is fixed a bracket for carrying the driving apparatus, consisting of a cone pulley and back gearing, in all respects the same as for a lather. To the base is fixed a pillar for carrying the jib and its connections; it is a hollow tube with three turned bearings, and is embraced by a frame provided with V's, on which the jib slides up and down and turns horizontally round the mast on the three bearings before named. The jib is capable of turning upon a centre bearing provided in the hollow shield cast on the sliding piece by means of a worm and worm wheel L, through an entire revolution, and can be fixed in any position by means of bolts in the circular T-groove in the shield. To the jib is attached a saddle capable of traversing to the extent of 3ft. along the jib by means of a screw and nut, in the usual manner. The drill headstock is attached to the saddle by

means of bolts in a circular T-groove, and is capable of being turned through and entire revolution if required and fixed in any desired position by the bolts in the T-groove. The tube surrounding the drill spindle has its lower bearing conical and capable of being adjusted to the greatest nicety by means of lock nuts and washers at its upper end; there is also a similar adjustment between spindle and feed screw, and between the nut and screw, the former being made in halves, thus insuring accuracy of speed.

Motion is conveyed to the drill spindle in the following manner:—On the end of the cone pulley shaft A is fixed a bevel pinion, gearing with a bevel wheel on the lower end of the shaft passing upwards and through the pillar and on its top end, carrying a spur wheel E, gearing into another spur wheel on a shaft sliding through its boss, and having its lower end in a bearing in the shield F, and carrying a bevel pinion, gearing into a bevel wheel, neither shown, on the end of the shaft passing to the outer end of the jib, on which shaft is the sliding bevel pinion, gearing with the bevel wheel, attached to the mitre wheel G, in the centre of the saddle and headstock, which latter wheel G gears with the mitre wheel H, on the tube surrounding the drill spindle, which latter is carried round with the tube by two sunk keys on either side, fitted into two long grooves in the spindle to allow of a rise and fall in the spindle.

allow of a rise and fall in the spindle.

The drill has a downward traverse of 15in. from the tube, and the self-acting movement is accomplished in the following manner:—On the tube is keyed the mitre wheel K, gearing with a similar wheel on the short shaft, on the opposite end of which is a cone pulley communicating motion to another cone pulley on the end of the worm shaft, the worm gearing with the worm wheel M, on the lower end of the vertical shaft; at the top end is a spar wheel, gearing with a spur wheel, on the nut which surrounds the feed screw, the said screw being prevented turning with the wheel by a key fitted to a groove cut in the threads of the screw, and attached to the drill headstock. The feed motion can be connected and disconnected at pleasure by means of the friction cone on the worm wheel shaft. The

jib is moved horizontally round the mast by means of a worm and wheel L attached to the lower end of the frame surrounding the pillar and retained in any desired position by means of set screws and buttons at the back of each bearing. The self-acting movement for raising and lowering the jib consists simply of a square-threaded screw, working in a nut attached to the sliding piece on the front of the frame. The screw is caused to revolve in opposite directions by means of connecting or disconnecting pinions with another carried on the top of the vertical shaft passing through the pillar. The wheels for this object are shown at O, and are thrown in and out of gear at pleasure by means of an eccentric attached to the top end of the vertical shaft passing from bottom to top of the frame; the eccentric attached to the top end of the frame; the eccentric scoupled to an arm carrying the wheels by a short link, by turning the handle X at the bottom of the shaft to the right or left, or at midway, so is the motion of the jib up, down, or stationary. Three notches are provided for the handle to fall into and lock at each of the three points.

The jib has a horizontal radial movement round the mast to work at opposite sides of the base or over a pit, at one or both sides, as desired, for acting upon large objects of unusual length; it has a vertical movement of 3ft., and the saddle has a horizontal traverse along the jib arms of the same extent, viz., from the centre of pillar to the centre of the drill spindle, 2ft. 9in. to 5ft. 9in., from the same centres when at the extreme end. The machine is capable of drilling, boring, and facing in any and all the positions of the jib or headstock, enabling it to work upon various descriptions of frames not otherwise accessible to ordinary tools; and, owing to its unusual strength of parts and weight of the castings, its action is smooth and steady.

#### EQUILIBRIUM SLIDE VALVE.

MR. JOSEPH E. OUTRIDGE, of 24, Hearnstreet, Newport, Isle of Wight, has recently patented an improved slide valve, which is illustrated in the annexed engravings. By his inven-

tion, the pressure of steam and vacuum is removed from the valves, and their free working is obtained without friction upon their faces. He accomplishes this by attaching to the ordinary valve box of a steam engine an apparatus consisting of one or more castings, each of which contains ports or passages for the inlet and outlet of the steam. The faces of the castings are opposite to, and fixed parallel to, each other. Between these faces a single or double slide is placed, each of which has an aperture in it whereby the communication from passage to passage is perfectly free. When a double slide is used, blades of brass or other metal are placed upon the parts of the slide exposed to the steam to prevent a passage beexposes to the stream of parts. Any necessary pressure upon the valve is provided for by means of a lever affixed to the slide rod; that part of the rod which holds the valve being flat, will keep the valve or valves to their faces.

Fig. 1 of our engraving is a top view of one of Fig. 1 of our engraving is a top view of one of these valves, the top cover of the valve box being removed. Fig. 2 is a longitudinal section, and fig. 3 a transverse section, of the valve applied to an ordinary steam cylinder. Fig. 4 is a perspective view of the casting before referred to. a is the cylinder, b the valve box, c the casting, and d the slide, which is single; ef are the two ports communicating between the valve box and the front and back of the cylinder. The casting c has two opposite faces, and is provided with a port or passage a in each face to communicate port or passage g in each face to communicate with the port e, and a port or passage h in each face to communicate with the port f. The casting is also formed with a central exhaust opening or port i corresponding with a similar opening k in the slide d; l is the steam supply pipe, and m the exhaust. In the forward movement of the valve the slide d passes the ports h in the casting, thereby allowing the steam to pass from the valve box through these ports h to the port f, and thence to the back end of the cylinder. The opening k of the slide also, in the forward movement, uncovers the ports g in the casting, allowing the steam in front of the cylinder to exhaust through the port e, ports g, openings & and i, and passage m. The bottom face of the slide d is kept a little above the bottom of the casting c, to allow the steam to flow between them. x is a lever on the slide rod; when pressure is put upon this lever, the flat part of the slide rod keeps the slides to their faces.

Fig. 5 is a perspective view, and fig. 6 a transverse section, showing a slide made double or in two parts, blades n of brass or other metal being placed around the slide to prevent steam passing between the two parts. Figs. 7 and 8 show one of the castings made with wedge-shaped faces or faces inclined to one another to receive a wedgeshaped valve and valves.

e understand that one of Mr. Outridge's valves has been at work on a locomotive engine on the Cowes and Nowport Railway since December 21 last, and has run 3,150 miles up to the present time, without any defect whatever, and continues to work well and satisfactorily. Another engine on the Ryde and Shanklin Railway, has just been fitted with one of these valves, and we expect to receive the particulars of the trial next week.

#### LONDON ASSOCIATION OF FOREMEN ENGINEERS.

ON Saturday, the 6th inst., the ordinary monthly meeting of members to meeting of members took place at the George Hotel, Aldermanbury, City, Mr. J. Newton, Royal Mint, president, in the chair. The sitting was principally devoted to business closely connected with the institution, and it was very numerously attended. After the confirmation of minutes of preceding meeting, the nomination and election of new members was proceeded with. These latter operations occupied a considerable portion of the evening, for never since the formation of the Association were the candidates for admission, on any one occasion, so numerous. Each election is ceded by a statement of the individual qualifications of the would-be associate, and then an open vote is taken; a majority of at least two-thirds of

Post Office; George Robertson, of Leadenhall-street; and Thomas Hall, of Bouverie-street.
Mr. William Thorburn, general foreman to Messrs. David Napier and Sons, Yorld-road, Lambeth, was elected an ordinary member; and Messrs. T. Hughes, J. F. Wolff, J. E. Reed, H. Noble, R. Wood, and J. Bates, were nominated in the same

category.

It now seems evident that employers and em ployed are alike interested in the progress of the Association, and equally determined to promote its Under such circumstances, the institution cannot fail to increase in influence and importance, and that to an extent as yet scarcely calculable. In view of this prosperous state of affairs, it was unanimously resolved that the local habita tion of the society should thenceforth be transferred to more commodious quarters, namely, the City Terminus Hotel, and where its future sittings will therefore be held. It was also announced that Professor Tyndall would, in all probability, deliver an inaugural and scientific lecture before the associated foremen, at their new rooms, on the evening of Saturday, April 3 next. Arrangements having been made for announcing, week by week, in the advertisement columns of the "Engineer" and the MECHANICS' MAGAZINE, the special qualifications for posts in engineering establishments, of such associates as may be unemployed, and some minor business disposed of, the meeting of last week was brought to a conclusion.

N XYLOGRAPHY, OR PRINTING AND GRAINING FROM THE NATURAL SURFACES OF WOOD.

By Mr. William Dean, Sen. (Concluded from page 179).

SHALL deal with the question of cost as I have I SHALL deal with the question of cost as I have dealt with the question of quality, and point out what has been done under the patent in a given time. I may, however, remark here, that there are plenty of painters, in London and the country, who say that they can get graining done at 5d, and 6d, pr yard. I do not deny the statement, for I heard one gentleman say that the men who did his graining got through a great deal of work, for they did it with whitewash brushes, and for aught he knew (or berhaps cared), it answered as well as if it were whitewash brushes, and for aught he knew (or perhaps cared), it answered as well as if it were more costly. There are others, however, who are candid enough to admit that for good oak-graining they have often to pay 2s. and 2s. 6d. per yard. Among the latter, I have pleasure in mentioning Mr. Foxley, of London. I have it on the authority of Mr. Crossley, of Newark, that he paid to a London grainer £50 for graining fifty doors for him, in a house he was decorating in the metropolis for, I believe, a Nottinghamshire gentleman; but Mr. Crossley declined to affirm that the hand-graining he paid so high a price for was equal in quality to my specimens. cimens.

A painter in Burslem was anxious to see some A painter in Burslem was anxious to see some work done by the process in his own house; a man and boy were sent over to do some, and they grained two six-panelled doors in twenty minutes by the clock. The wife of the painter told me she watched the clock with the special object of ascertaining how long it took to do them. The same man and boy grained an octagon pulpit for another painter, about three miles from Burslem, in an hour and twenty minutes. Both these painters purchased licenses. When Messrs. Simmons and Son, of Mauchester, purchased a second machine, I gave one of their men instructions in working the process, and after three days practice, I asked him, about the quantity of work he could do as compared with hand graining, and he informed me that he was quite sure he could do one ne could do as compared with nang graining, and ne informed me that he was quite sure he could do one-third more than by hand, and much more easily and pleasantly to himself. At the North Staffordshire Railway Company's works, when giving instruction to their foreman, I myself grained ten square yards of imitation East India teak in two hours by the watch, and this was done in the same compartments with and this was done in the same compartments with solid teak, and had to match it. I had a young man to assist me, such as the hand grainer has to rub his colour in for him.

colour in for him.

Perhaps, after all, the most conclusive illustration of success in price is supplied by its application to japanned goods. You are all probably aware that the graining on that class of goods is of the best kind. In Wolverhampton, I was told by the leading manufacturers, that successful competition in price with hand graining on their goods was out of the question. From that conclusion, however, I dissented, and I told them so. From Wolverhampton I went those present being required to secure admission. The following gentlemen were unanimously elected as honorary members:—Messrs. George Waller, of the firm of Burton, Sons, and Waller, Holland-street, Blackfriars-road; Edward R. Allfrey, of the firm of Messrs. Humphrys and Tennant, Deptford; Richard Moreland, sen., of the firm of Messrs. Humphrys and Tennant, Deptford; Richard Moreland, sen., of the firm of Messrs. Humphrys and Tennant, Tene I met a gentleman from London, unconnected with the japanning trade, who bought the exclusive licence for that class of goods to British and Sons, of Granville-street, for a price which left him a very handsome profit. I need not hesitate to affirm that if the process will compete successfully in price with hand graining on japanned goods, it will compete in price with any street; Frank Ives Scudamore, Secretary General

not have given the price they did for an exclusive licence if they had not satisfied themselves on that point. Fourteen months ago, I supplied them with one machine, and set them to work, and in about six months after, they wrote to me to forward them two more machines.

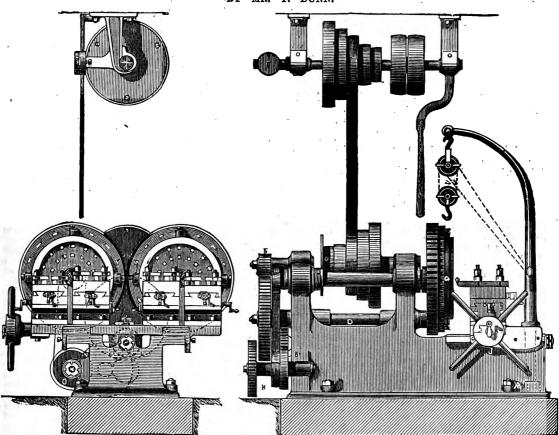

more machines.

The question of durability has been raised, and properly so, as that is a point of great importance to the public. To enable you to judge, I may say that the hand-grainer works in distemper, I in oil colours; and it resolves itself into the old question, which is the more durable, water colours or oil colours? After all, the test of experience is the most constant of the colours of the colours of the colours of the colours. After all, the test of experience is the most conclusive and matisfactory; and here again I must refer to my specimens, as the large one has been done more than three years, and has had a good deal of knocking about at exhibitions, and travelling through the country. If a good sound varnish is used, I have no hesitation in saying that the work will be very durable, and much more so than work done by hard.

done by hand. In applying the subject to the exigencies of our condition as a commercial country, shall I be far from the truth if I hazard the remark that in this department of our operations there is great room for improvement? I am supported in this view by what occurred in a conversation I had with an architect in the provinces. Substantially, it was as follows:—I said to him, "The painters and decorators tell me I said to him, "The painters and decorators tell me that graining is going out; that architects will not have it, and are either staining the plain deal, or using parti-colours instead in their decorations." He replied, "To some extent that is true, and the chief reason is, not so much that they object to graining in the abstract, as that they object to the kind of graining they have done for them. They would only be too delighted to have it done as good as your samples, for these are beautiful and true to nature." Now, God has implanted in the hum mind a love of the beautiful and the true; hence t kind of graining they have done for them. They would only be too delighted to have it done as good as your samples, for these are beautiful and true to nature." Now, God has implanted in the hum mind a love of the beautiful and the true; hence t merchant hastens away, and, amid the beauties nature, forgets for the time the cares and anxietie of the counting-house and the exchange, and the artizan the toils of the workshop; each rejoices in beholding the loveliness of the landscape, and contemplates with delight the gorgeous and varied verdure of the trees; but how few there are who reflect and pender on the marvellous internal structure of those trees which grow in our woods and hedgerows, so full of elaborate ornament, feathered, flowered, striated, and dotted, in patterns of perfect, and sometimes of complex beauty, to an extent that no graving done with the graver's tool can equal in gracefulness of design or in strength and delicacy of touch, Hitherto, these patterns of wondrous beauty have been imitated by the cunning hand of man with his pencil or his graver; but this process will inaugurate a new era, and these exquisitely beautiful patterns will be reprodueed in almost endless variety. The letter-press printer reproduces old and scarce books, and the chromo-lith-grapher reproduces rare and costly pictures, and this at a price that places them within the reach and means of the general public. So this process is designed to make accessible to the community in general copies of the more than artistic beauties of a part, though it be but a small part, of the glorious works of God. I flatter myseli that I can, even at this early stage of the process, produce as fine a copy of achoice piece of Baltic billet oak, as the chromolithographer can produce of Stanfield's "Venice," Turner's "Polyphemus," or any other fine work of art. In conclusion, will you permit me to say that in dealing with the subject under consideration, I have, to a large extent, kept my own opinion of its merits in abeyance; I have asserted success; that nothing but the sternest necessity has prevented Mr. William Simmons from being present this evening. A better testimony to its practical value it would be difficult for me to give yon. To that firm I have great pleasure in thus publicly expressing my indebtedness, for they not only lent me a helping hand when help was of more value to me than it is to-day, but they readily permitted me to refer to them, and gave themselves the additional trouble of taking persons in the trade from other towns to see the work they had done under the patent.

### DUPLEX TIRE LATHE.

BY MR. T. DUNN.

DUPLEX TIRE LATHE

DUPLEX TIRE LATHE.

ABOVE we give a side and an end elevation of a duplex tire lathe, with two or four tools working simultaneously, the invention of Mr. T. Dunn. a is the bed, to which are cast or fixed the bearings a 1 for the driving spindles b and c, and for the centre spindle on which the speed pulleys are fixed. To one end of the centre spindle is fixed a pinion gearing into the wheel fixed to one end of the shaft, to the other end of which is fixed a pinion, gearing into the teeth on the circumference of the face plate C; the other face plate is driven from the face plate C, as shown. The four slide rests are all mounted on the cross bed, which is traversed along the bed a by the screw in the following manner:—To the spindle b are fixed the speed pulley, driving by a strap the pulleys o; to following manner:—To the spindle b are fixed the speed pulley, driving by a strap the pulleys o; to these pulleys is fixed the pinion, gearing into the wheel fixed to the same shaft as the pinion gearing into the wheel, which drives the wheel on the end of the screw. This screw gears into two worm wheels, as shown; the upper of these worm wheels is fixed to the shaft of the spoke wheel or cross handle, and the lower one is fixed to a short shaft which is driven by means of the spur wheels. The shafts of the worm wheels revolve in hearings shafts of the worm wheels revolve in bearings fixed to the cross bed. When the screw is moving the slide rests, the worm wheels act as a screw nut, but when it is desirable to move the slide rests by hand the tightening handle is slackened; and on then turning the spoke wheel the worm wheels act as a single and the savent height streams and the savent height streams. as pinions, and the screw being stationary acts as a rack. It is evident that the tool of each slide rest can be moved independently of the others; consequently, two of the tools can be made to bore out the tires or other articles, and the other two to turn up the exteriors. The bed a and the beds of the sile of the other lathes can be made with a socket for the jib crane p, which supports a pair of blocks for lifting the tires and other articles into and out of place.

## MANCHESTER STEAM USERS' ASSOCIATION.

ON Tuesday last the annual meeting of the above Association, which has hitherto been known as the Association for the prevention of steam boiler explosions, was held at the Town Hall, Manchester, Dr. Fairbairn, President of the Association, in the chair. Mr. R. Tonge, the secretary,

read the report for the past year, the details of which have for the most part appeared in our columns from time to time. It is, therefore, only necessary here to refer to the satisfactory position of the Association, and to the resolutions passed at the meeting. The number of members of the the meeting. Association on the 31st of December last was 573; works, 747; boilers under inspection, 1,930; subscription, special service fees, &c., £3,944. The revenue of the Association for the past year has revenue of the Association for the past year has attained to a higher point than during any previous one, and there is a balance in favour of the year's working of £305. The reserved fund is increased by this sum, the amount of that fund now being £2,797, which, added to the guarantee of £13,000, makes the total value of the guarantee fund on the 31st of December, 1868, £15,797. The number of corresponding members of the Association has again increased during the year. There were, on the 31st of December, fifty members of this class. again increased during the year. There were, on the 31st of December, fifty members of this class, forty-two being resident in the United Kingdom, one in Naples, one in Switzerland, one in Dresden, Saxony, one in Vienna, two in Calcutta, one in New York, and one in Amsterdam. There were fifty-nine boilers more under inspection at the close of 1868 than there were at the close of 1869, and a greater number upon the books of the Association on the former date than ever before.

Some highly practical remarks were made by the chairman upon the general subject of steam, in the course of which he observed that experiments were in progress to prove the efficiency of high attenuated steam, worked at pressures vary-ing from 180lb. to 200lb. down to that of the ing from 1801b. to 2001b. down to that of the atmosphere, and ultimately condensed. After this Mr. R. H. Greg, of Stockport, moved the next resolution:—"That the name of this Association be modified, and instead of remaining as at present 'The Association for the Prevention of Steam Boiler Explosions, and for the Attainment of Economy in the Use of Steam,' that it be henceforward 'The Manchester Steam Users' Association for the Prevention of Steam Boiler Explosions.

arousing public attention to the present unsatisfactory character of the investigations conducted by coroners regarding the cause of steam boiler explosions, as well as to the erroneous verdicts constantly returned, and requests the committee of management to take such further steps as they may find necessary to secure these investigations being rendered more satisfactory, so that the truth may be fully arrived at, and plainly spoken in each may be fully arrived at, and plainly spoken in each case, in order to prevent the constant recurrence of these fatal catastrophes." He believed that under a more rigorous system of inquiry into the so-called accidents, employers would be compelled to be much more careful, and the result would be an immense saving of human life. Mr. C. J. Pooley, in seconding the resolution, pointed out how, on scientific grounds, these inquiries should be conducted in a more complete manner than at present. Mr. W. Richardson, of Oldham, supported the resolution, which was carried.

the resolution, which was carried.

Mr. S. Rigby, of Warrington, moved:—"That
the benefits derived from membership with this Association are not confined to questions of safety merely, but embrace others of importance to steam users, such as the prevention of smoke, the steam users, such as the prevention of smoke, the best construction and equipment of boilers, &c." Mr. Cowell, of Patricroft, seconded the resolution, which was adopted. Thanks were voted to the officers of the Association for their services during the year, and those for the ensuing year were relected or appointed; and the proceedings terminated with a special vote of thanks to the chairman for presiding at the meeting, as well as for his interest in, and constant service to, the Association. Association.

## HEAVY PUMPS WORKING IN A SLOPE OF 1 IN 4.

Boiler Explosions, and for the Attainment of Economy in the Use of Steam,' that it be henceforward 'The Manchester Steam Users' Association, for the Prevention of Steam Boiler Explosions, and for the Attainment of Economy in the Application of Steam,' so that it may be cited in brief as 'The Manchester Steam Users' Association.'" Mr. Jabez Johnson, of Bolton, seconded the motion, which was carried nem. com.

Mr. Thomas Schofield, of Cornbrook, moved:—
"That this meeting hears with satisfaction that steps have been taken during the past year for

increased length of the column, the resistance due to riction is greater than if the pumps worked in a vertical shaft; but this is fully compensated for by the adva tage afforded for a larger ratio of expanthe adva stage afforded for a larger ratio of expansion, in virtue of the increased momentum from thadditional length and weight of pump-rads put in motion each stroke, and the work was specially designed by Mr. Morgan Morgans, of Bristol, to secure this advantage. It is important to find that pumps can be made to answer well in this manner, and it was once proposed to sink a shaft at this colliery purposely to avoid the disadvantages which were thought to be inseparable from slope pumps, but the chief of which have been, in this case, entirely overcome by Mr. Morgans, whose experience in draining mines is well known.

## THE GOVERNMENT MEMORANDUM TO INVENTORS.

THE relations subsisting between inventors and various branches of the Government, needing and using the intelligence of inventors, has long constituted a topic of painful comment and incrimination. The War and Admiralty departments have so often been made fields of conflict between the advocates of two widely divergent and conflicting opinions, that, speaking on behalf of inventors generally, no less than of the Government, we would gladly hear of some equitable basis of agreement come to, whereby the two antagonistic parties might be satisfied. In considering this matter, the first question to suggestitelf is, why should there be any antagonism? Either the governmental departments—especially the War Office and Admiralty—are independent of extraneous inventive aid, or they are not. If they are, then the practice would be comprehensible of looking upon inventors as a troublesome lot, of repelling their advances, giving them curtly and sumlooking upon inventors as a troublesome lot, of repelling their advances, giving them curtly and summarily to understand that the State is in no need of them, and will neither treat with them, nor countenance them in any way. If, on the other hand, they are wanted—if Government departments feel themselves under the need of using extraneous inventions from time to time, then one of two courses is open: either give inventors to understand that the Government, being strong, will take what it likes, paying no equivalent, or else assess the fitting remuneration by some tribunal impartially constituted naving it either give inventors to understand that the Government, being strong, will take what it likes, paying no equivalent, or else assess the fitting remuneration by some tribunal impartially constituted, paying it promptly and without demur. In matters of disputed value and rate of remuneration generally, the practical worth of a thing is what the owner could exact payment in respect of before the tribunal of the law; but the fact cannot be too prominently borne in mind that, as between the British Government and inventors whose inventions are adopted by the Government, a flat of outlawry went forth in the verdict of the cause "Feather v. the Queen." British law regards every inventor as an outlaw; as a man having no legal rights in any matter relative to the use of his invention by the Government. It would be an insult to the reader's intelligence were we to debate the moral right and wrong of this decree. We only state what is the law, expressing at the same time our conviction that public opinion would never second or sanction the strict upholding of this, in any case of undisputed use and adoption by a governmental department of an invention originating with a member of the public. Not wishing to overrate the grievances inventors have complained of in the course of their dealings with the Government, we are free to admit, that although the legal ruling is precisely as we have stated, yet the cases of inventors whose inventions have been adopted by the Government remaining totally unrewarded are comparatively few. Usually, some bonus has been conceded, but the manner of this assessment and award has been hitherto most unsatisfactory. Government in these manters has acted as though prompted by the desire to give an inventor the very maximum of trouble; to tire him out by all sorts of unnecessary delay, whereby in time his hopes and aspirations might be lowered to a convenient despair for inducing him to accept a trifle. The statement has often gone forth, in these columns as well as elsewhere—it is one, moreover, adjudication of reward to inventors devolved on the legal heads of departments, who were allowed a percentage commission on any abatement they might succeed in effecting. Nothing could be more unfair than this; few arrangements more prejudical both to inventors and the Government can be assumed. Indications, we are gratified to state, are not wanting that Mr. Gladstone's administration is not insensible to the past injustice to which we have referred, and is resolved that inventors coming before governmental departments, and having their inventions ultimately adopted. shall be equitably treated in future. The first indication is seen in the terms of a recent memorial announcement issued from the War Office, for the consideration of inventors, whereby various checks are imposed to the suppression of a valuable invention; first, establishing a more fairly const tuted tribunal than heretofore for the assessment of value; secondly, defining the mode of payment and indication is a second to the suppression of a valuable invention; first, establishing a more fairly const tuted tribunal than heretofore for the assessment of value; secondly, defining the mode of payment and indication is a second indication. ment of value; secondly, defining the mode of pay-ment, and indicating the precise time. In former days, if a man possessed an invention bearing upon

warlike art, and wished to treat on behalf of the same with the Government, his usual course of pro-ceeding was the following. He made application either to the War Office, the Ordnanace Select Comceeding was the following. He made application either to the War Office, the Ordnanace Select Committee, or the Admiralty. His letter of communication met a prompt response, accompanied with a printed statement of the terms on which alone the Government would condescend to treat with him. He must defray all expenses: he must disclose all particulars; flually, he must trust wholly and absolutely to Government for reward in the event of ultimate adoption. Now, the common opinion is (and it is one that, conscientiously, having arrived at belief through evidence within our own knowledge, we cannot gainsay) that, on many occasions, inventive particulars thus communicated to the War and Admiralty departments have been turned to unfair account: that, by some means or other, those particulars have become known to members of the public service, "improved," ostensibly, at least, into discoveries of their own, to their sole advantage. If this did not happen, it readily might have happened. So powerful an incentive to profitably unfair dealing, without much chance of discovery, should never have been permitted. By the terms and wording of the memorandum, we are glad to see a check imposed on this contigency of unfair dealing. Inventors now regiven to understand that their communications are not to be addressed to either of the War Departments but contigency of unfair dealing. Inventors now regiven to understand that their communications are not to be addressed to either of the War Departments, but to one of the Under Secretaries of State, who takes upon hinself the responsibility of laying them before the War Department, where due consideration is pledged. The Government do not hold themselves responsible for any expenses an inventor may have incurred in the inceptive stages of an invention, but expresses readiness, under certain circumstances, to contribute towards expenses necessary to the developincurred in the inceptive stages of an invention, our expresses readiness, under certain circumstances, to contribute towards expenses necessary to the development of an invention. The next point of importance in the recent memorandum is relative to the tribunal of assessment, which is to be a committee held in the War Office, a great improvement on the old mode of leaving this matter to the discretion of the legal heads of departments. Whether or not any civilian element is contemplated in these War Office committees of adjudication the memorandum does not state; but if not, the machinery will be needlessly defective. Lastly, as regards time and mode of payment in behalf of inventions deemed worthy of acceptance and adopted, these matters—so important to ance and adopted, these matters—so important to inventors—are by the memorandum clearly defined. As soon as the value of an accepted invention has inventors—are by the memorandum clearly defined. As soon as the value of an accepted invention has been assessed, the sum—under sanction of the Secretary of State—is to be inserted in the estimates, when, on being passed by the House (but not till then) the inventor will receive his award. The new regime may be said to have found its first application in the award to Captain Moncrieff; for, although Government had come to a conclusion in respect to this matter before the memorandum to which we have been referring was issued, yet the spirit of it is clearly seen in the terms and manner of Captain Moncrieff's award. Altogether, the aggregate sum receivable from the Government by this gentleman may be set down as some £20,000. After paying him for the expenses of drawings, models, &c.—a concession rather in advance, by the way, of the terms of the new convention—he is to have £10,000 on the passing of estimates, and £5,000 more at the date when his assistance may be no longer required by Government in further developing his system. He is to be paid £1,000 per year for such time as he has been already assisting the Government, and for all future time until his services are no longer required. Then he is to receive £5,000. Altogether, this is an arrangement more liberal—as we have already said—than the new memorandum strictly required. Then he is to receive £0,000. Altograms, this is an arrangement more liberal—as we have already said—than the new memorandum, strictly would warrant inventors to expect. All already said—than the new memorandum, strictly interpreted, would warrant inventors to expect. All the better, is what we say; and if this liberality of treatment is to be repeated, all the better still. The English public, we are right sure, will never uphold unfairness by the Government to inventors who have advanced the interests or increased the power of any public department.—"The Engineer."

# PROPOSED NEW WORKS AND MACHINERY FOR THE NAVY.

FOR THE NAVY.

THE new estimates under this head provide for an expenditure of £749,816, which is a decrease of £64,421 on that of the previous year. The principal items of expenditure are at Chatham, where there is to be an increase of £39,485 in a total of £269,190; and at Portsmouth, where the expenditure under this head is proposed to be £264,630. For new works and naval establishments abroad the proposed sum is £59,217, showing a reduction of £51,862. The extension of Chatham Yard, which was originally estimated to cost £4,250,000, and on which £672,607 has been already expended, has a sum of £285,000 appropriated to it. For the extension of Portsmouth Dockyard, which was first estimated at £1,508,000, and on which £389,828 has been expended, the sum to be voted in the present year is £279,284. In the works abroad are included a vote for the extension of the mole at Gibraltar of £4,000, this was originally estimated to cost £122,500, and has cost up to the present time £88,149. At Malta an expenditure is proposed

of £30,000 towards the construction of a dock, wharves, &c., which were originally estimated to cost £195,000, and on which £81.225 has already been spent. In the item of machinery, under the whole vote for the works, there is a total decrease of £26.211.

REGISTERING THE FORCE AND DIRECTION OF THE WIND.\*

By Mr. Thomas Mackereth, F.R.A.S., F.M.S.

HAVE for a long time been wishful to obtain a simple instrument by which I could record, in a satisfactory manner, the exact force and direction of the wind. I am aware that records are made by Osler's anemometer, but I have many objections to it. The first is, that its mode of recording the exact degree of the compass whence each pressure of the wind has come is so cramped, that it is impossible to determine such a degree from the record. The second objection is that it is impossible from its record to determine the mean direction of the wind for any given time. The third is that its system of machinery appears so complicated as, in my opinion, to leave doubt whether its records are reliable. The immense pressures it is said to have recorded at Liverpool, for instance, are, in my estimation, very questionable. Then the great cost of the instrument, and its requiring an ordinary building to be adapted for its use, must preclude its employment by the many meteorological observers we have in the country

Up to the time of the great storms which occurred on February 22 and March & last year, I had a pressure anemometer which was made and kindly given to me by my friend William Oxley, Esq. That this instrument recorded the exact pressures of the wind, I have abundant testimony. The greatest pressures of the storms I have mentioned was 321b, on the square foot. That was the highest pressure the instrument was capable of recording, and I believe, from other pressures which I witnessed during the same storms, that if the instru-ment could have recorded a higher pressure, especially on February 22, it would not have reached above 40lb. on the square foot. But it is reported that during the storm of February 22, a pressure was at Liverpool of more than 70lb. on the square foot; and on December 27, 80lb. on the square foot was recorded. I confess it is with difficulty that I receive such a report. Probably the height at which the Liverpool instrument is placed may

which the Invertool instrument is placed may give some value to the record.

Whilst I was arranging with Mr. W. Oxley for an instrument that would record higher pressures, I met with a description of an anemometer in the "Proceedings" of the Meteorological Society, vol. 4, page 161. My first objection was to the fcllowing statement respecting the pressure of the wind in this country:—"The greatest pressure here provided for is 20lb. on the square foot, which is sufficient for the winds that occur in this country, as proved by careful experiment." Cercountry, as proved by careful experiment." Certainly such a statement is very far at variance with the records that are said to have been made at Liverpoel, or even at Greenwich. However, I and Mr. Oxley gave the instrument a careful consideration, and at length abandoned it as a means of recording such high pressures as we were sure had been recorded. Besides this, its mode of recording the directions whence the high pressures come is far too complicated and confusing. I at length suggested that Mr. Oxley's own an emometer length suggested that Mr. Oxley's own anemometer could be made to accomplish all that this instrument professes to do, and in a much more effectual manner. But no sooner were my ideas thrown out, than my friend's mechanical skill accomplished what was wanted in the simple manner in which it now exists.

This instrument does not profess to record the This instrument does not profess to record the time when the pressures occur, though an arrangement could easily be adapted for this purpose. In this respect alone is it inferior to Osler's anemometer. But as every observer of the wind is furnished with Mr. Robinson's anemometer, the hourly records of this instrument would afford the means of a ready estimate of the time when the means of a ready estimate of the time when the heaviest pressures occur. By means of Mr. Oxley's anemometer, I am able to record the variations of the wind for twenty-four hours, the exact degree of the compass whence each pressure comes, and, from the daily curve, to reduce in a most satisfactory manner the mean direction and range of the wind, as well as the mean direction of the heaviest pressures. I consider it of the greatest importance to trace out the exact point of the

\* Manchester Literary and Philosophical Society.

compass whence every great pressure comes. Ιf this were done at all our stations in this country, it would tend to a better understanding of the course storms take, and of the connection between the fall of rain and the direction of the wind.

STEAM SHIPBUILDING ON THE CLYDE

MESSRS. R. DUNCAN and Co., of Port Glasgow LESSRS. R. DUNCAN and Co., of Fort Glasgow, have contracted to build a screw of 1,000 tons for Mr. R. Little, of Greenock. Messrs. Randolph, Elder, and Co., have launched the "Patagonia," a vessel of 3,000 tons burden, builder's Randolph, Elder, and Co., have launched the "Patagonia," a vessel of 3,000 tons burden, builder's measurement, and 600-horse power nominal. The "Patagonia" has been built to the order of the Pacific Steam Navigation Company, and is a sister ship to the "Magellan," lately launched by Messrs. Randolph, Elder, and Co.; she is intended for the company's direct mail line between Liverpool and Valparaiso. Her engines, which are being supplied by Messrs. Randolph, Elder, and Co., are constructed upon their patent compound principle. Messrs. R. Duncan and Co., of Port Glasgow, have launched an iron screw named the "Cambria" of the following dimensions:—Length, 315ft.; breadth, 85ft.; depth, 22ft. 6in.; burden, 2,000 tons. The "Cambria" will form one of the Anchor Line from Glasgow to New York. Messrs. W. Hamilton and Co. have launched from their yard at Port Glasgow a paddle named the "Osmanby," built for the Ottoman Government. The "Osmanby," which is a strongly-built wooden steamer, is of the following dimensions:—Length, 178ft.; breadth, 21ft.; depth, 10ft.; and burden, 370 tons.

#### AERIAL NAVIGATION.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,-Permit me to draw your attention to a new system of aerial navigation, as represented in the enclosed photograph, and which is the invention of myself and Mr. J. Lassie. The aerial vessel is of nived and Mr. J. Lassie. The serial vessel is of sufficient capacity to contain a volume of gas suffi-cient to lift and carry up the whole apparatus, At summent capacity to contain a volume of gas sufficient to lift and carry up the whole apparatus. At the same time, it has the most perfect form for progressive motion, and also possesses propelling force so that it may be driven and steered in any direction. An arrangement is made for varying the ballast at pleasure, so that the aerial ship can be made to ascend, descend, or remain stationary without any loss of the gas by which it has been raised.

The most appropriate construction for an aerial ship, so that steerage may be practicable, is an iron or

an aluminium cylinder, whose length is at least ten times its diameter. The lifting power is obtained from hydrogen gas, the necessary quantity of which is stored in a receiver, which is provided within the vessel, and is so constructed that equal volumes of gas always act upon equal lengths of the axis. This cylinder is surrounded for its whole length by three spiral flanges or wings of about one-sixth part of the cylinder, each spiral flange making about two turns in the whole length, so as to look like a scrow whose ends are either conical or hemispherical.

In a vessel so constructed, it will be evident that if a rotary motion be given to the cylinder it must advance in the direction of its axis, with a velocity proportioned to the velocity of rotation; in other words, the screw will move forward in proportion to the rapidity with which it is made to revolve, and also in proportion to the developed surfaces of the spirals. Within the outer or main cylinder is a second cylinder of less diameter, and connected with the first by a system of metallic tubes and wire supports. The space is closed at the ends, and is capable of holding the requisite quantity of gas, and also a series of air bags or chests to be presently described. This inner cylinder may be called the tunnel. It is the hold or cabin of the aerial ship, and is divided into compartments of 6ft. in width. In each of these compartments is a hammock, movable about the axis. The floor of each cabin is and is divided into compartments of 6ft. in width. In each of these compartments is a hammock, movable about the axis. The floor of each cabin is divided into steps like those of a tread-wheel, on which men working make the screw revolve about its axis, and thus propel the ship through the air, so that the walk of the men in the tunnel is proportioned to the travel of the screw ship as 1 = 18 × 3 flanges or, if the men walk one mile, the vessel will advance eighteen miles, and that in twenty minutes. This motion of progression being obtained, there is no difficulty in steering the vessel, which is effected by a smaller vessel—the length of which is about twice its diameter—attached to end of the ship, which performs the office of a rudder in the same manner as those of ships, and with like effect. This balloon rudder answers to the revolving motion, and is able to carry a great weight, and may be of utility for ebservations. It will also form the recond of the captain, who will be in immediate correspondence

captain, who will be in immediate correspondence with every cabin, either by electric wires or any other method of signalling.

The means of support or flotation and progression being thus obtained, we have next to provide a method of ballasting which is variable at pleasure, and by means of which the ship may be made either lighter or heavier, or of equal weight and density with the air in which it floats, thus enabling the navigator to alter or maintain any altitude which may be suitable to his purposes without any loss of gas on which he relies for the support or lifting power of his ship. To this end I propose the air for ballast, the density and weight being regulated by an apparatus as follows:—In the gas chamber are placed a series of oiled silk sacks, one opposite to each of the compartments into which the tunnel is divided. One end of each of these sacks opens by a valve under the steps upon which the men tread in producing the motion which propels the vessel. Each of these steps is arranged as a bellows, by means of which, at every step, air is forced into the sacks until the requisite weight is obtained for ballast. The other end of these sacks opens outward by another selfacting valve, each of these valves being under the control of the navigator. By this arrangement, the ballast of the ship may be increased or diminished at will. It will be seen that this construction also avoids all danger of explosion or collapse from any rapid change of temperature occurring in the journey.

The leading features of this new aerial ship are—that its density may be varied at will without loss of gas; its horizontal stability is perfect with every degree of the barometer; if inclined, the inclination will take place gradually and at will. I am prepared to prove the mathematical correctness of this principle and the safety of the vessel and crew.—I am, Sir, yours, &c.,

26, Grove-place, Brompton-road, March 8.

Sir, yours, &c., G. SEN 26, Grove-place, Brompton-road, March 8.

#### EXPLOSIVE COMPOUNDS.

EXPLOSIVE COMPOUNDS.

Sir.—I have but one recommendation for all objectors to white gunpowder, and that is, that they make a small sample and try it themselves, an operation they can easily perform in the space of ten minutes, as I have repeatedly published the process. I beg, however, to observe, in regard to the remarks of your anonymous correspondent "F. W. R." that the blowing out of unconsumed grains, which may be seen, without "superhuman oyesight," at any rife practice, was noticed, at least as far back as the year 1742, by the artillerist Benjamin Robins, who first made use of the ballistic pendulum for investigating the velocity of projectiles. Quick burning gunpowder is objected to by "F. W. R." and all gunmakers on the authority of Sir W. Armstrong, but that gentleman is no authority for me, for he had the description of the manufacture of wrought-iron coil guns, first published by me, in his own hands four years tion of the manufacture of wrought-iron coil guns, first published by me, in his own hands four years before the date of the so-called Armstrong patent for the same construction. It is absurd to contend that the slower the shot is driven out of the muzzle, the longer the range and the deeper the penetration; whereas, I or any one else can prove the contrary, by actual experiment, in the course of five minutes. The objections to quick burning powder arise solely from the defective construction of our guns, which have no solid block of metal behind the bottom of the chamber, and consequently such guns cannot stand the concussion caused by the explosion of powerful powder.

the concussion caused by the explosion of powerful powder.

The fact is, that white gunpowder, or any other novelty, acts upon "F. W. R." and all gunmakers as a red rag does upon a flock of turkeys, it drives them demented. That is to say, provided they cannot secure to themselves exclusive patent privileges that might enable them to make some little extra charge to their customers. I am quite ready to prove the power and safety of white powder at any time or place, by appointment, and take this opportunity to remind your anonymous correspondent "F. W. R." and others, that I am not the inventor, and have no pecuniary interest whatever in the manufacture of the powder which accidentally bears my name.—I am, Sir, yours, &c.,

HENRY W. REVELEY.

am, Sir, yours, &c.,

HENRY W. REVELEY.

1, Baker-street, Reading, March 8.

| We cannot understand why Sir W. Armstrong should not be an authority upon gunpowder, because he knew how Mr. Reveley proposed to make coil guns before he made his own. Of course Mr. Reveley implies that Sir W. Armstrong pirated his (Mr. R.'s) invention. But Sir William only specifically patented the method of producing the coils. If Mr. Reveley thinks himself the first inventor of coiled guns, we would refer him to a far more ancient example than he could produce. This is the gun "Mons Meg," mounted on Edinburgh Castle, which was fired with stone shot, and which is upon the coiled principle. The coils are clearly developed where a shot has broken a fragment off the piece. As we have the pleasure of "F. W. R.'s" acquaintance, it may be a guarantee to Mr. Reveley that he is not "demented," which Webster explains as being "imbecile in mind; infatuated." We wish our correspondents would always discuss science for its own sake, and in a meaner becoming scientific men, not sake, and in a manner becoming scientific men, imputing personal and interested motives unless the

are able to substantiate their position. Mr. Reveley may be very much infatuated (or "demented" if he likes the word better) with white gunpowder, but public opinion is against it. Mr. Reveley thinks it is unreasonably so, but does he not suppose, that if white gunpowder possessed all the qualifications it should for our public service, or even for private use, it would long since have been adopted in one direction or another.—ED. M. M.]

#### TO CORRESPONDENTS.

THE MECHANICS MAGAZINE is sent post-free to subscribers of £1 is. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

of £1 is. 8d, yearly, of 100. 100. Init-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED, M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d, per line, or 5d, per line for 13 insertions, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type, Special arrangements made for large advertisements.

SEVERAL of the Frazer or Woolwich 9-inch guns have been undergoing a further endurance test daily during the past week, having already completed firing 500 rounds. They now have to stand the test of 500 rounds more, making a total of 1,000 rounds with battering observes. with battering charges.

An Institution has just been established at Liverpool for the purpose of maintaining and educating the orphan children of seamen. It is specially designed to take charge of the girls, and the boys until they are of a proper age to draught off into the training ships, such as the "Indefatigable." A sum of £4,000 has already been subscribed.

A sum of £1,000 has already been subscribed.

By the death of Lord Gough, his Royal Highness the Duke of Cambridge becomes formally the senior officer of the British army. By length of service the senior is General Sir J. F. Fitzgerald, who entered the army in 1793. The others whose first commissions bear date before the present century are Field-Marshal Sir William Gomm, General Sir A. Clifton, Field-Marshal Sir A. Woodford, who date from 1704; General Sir W. Wood, from 1797; and Field-Marshal Sir John Burgoyne, from 1798.

THE number of established and hired mechanics a Chatham dockyard provided for in the Estimates for 1869-70 is 3,102, being a slight decrease on that of last year, the number in the former year being 3,131. Of this number 1,707 are "established" 3,131. Of this number 1,707 are "established" artizans, entitled to a superannuation allowance, and 1,303 hired men. The amount required to be voted for wages for the mechanics at Chatham dockyard during the approaching financial year is £180,581. as against £177,802 for the past year. The Estimates show that several offices are abolished, while the only one created is that of master ropemaker, at a salary of £260 per annum. The sum of £7,050 is provided generally for clerks and writers, the accountants, and the medical establishments but the whole of the establishments are stated to be "under revision."

THE death of General Sir Arthur Clifton, G. C. B. K. C. H., is announced at the advanced age of 97. The deceased was one of the heroes of the Peninsular war, and was actively engaged on the memorable 18th of June at Waterloo.

THE winter general meeting of the National Rifle Association was held yesterday week, at Willis's Rooms, his Royal Highness the Duke of Cambridge, K.G., president of the association, in the chair. From the report, it appeared that the total value of prizes competed for at the National, County, and Colonial Rifle Associations during last year was £27,693 2s. 8d., whereas in 1867 it was £25,546 17s. 10d. This statement shows an increase of 47 in the number of prizes; of these, the association had given 45. The decrease in the value of the prizes was £411 2s. 3d., but in 1867 prizes to the amount of £796 were allotted exclusively to the [Belgian visitors, and this amount increased the total value of the prizes competed for.

THE "West Florida Commercial," published in THE "West Florida Commercial," puonsneu in Pensacola, states that the two Peruvian ironclads, now lying off Warrington Navy-yard, performed in their voyage from the Mississippi to that point in a manner quite satisfactory to their officers. The greatest trouble experienced was from a want of air, and the intense heat which was a necessary consequence. The thermometer while the vessels were in motion indicated, as a minimum, 120deg. of heat, which is, to say the least, not a very agreeable temperature; indeed, it is stated that a number of robust firemen had to succumb before the vessels arrived at Pensacola. If in a stretch of a little over 100 miles a number of firemen were "burnt out," it is difficult to see how the officers of the fleet can hope to take the ironclads to their destination in

### Miscellanea.

THE number of visitors to the Patent Office THE number of visitors to the recommendation of the week ending Museum, South Kensington, for the week ending the source the source the source that the source March 6, was 4,173. Total number since the opening of the Museum, free daily (May 12, 1858), 1,515,636.

A DISPATCH from Montreal states that the snow in the streets of that place is eight feet deep, and some streets are almost impassable. A statement had been published showing that the fall of snow during the winter had been about 118in., which exceeded by 38in. the total fall in any year for 20 vears past.

Professor H. E. Roscoe, F.R.S., lately exhibited and explained to the members of the Manchester Literary and Philosophical (Society the method of producting ozone artificially, and showed how it had been proved by Dr. Andrews and M. Soret that ozone was an allotropic condition of oxygen, and that three volumes of oxygen formed two volumes of

THE number of visitors to the South Kensington THE number of visitors to the South Kensington Museum during the week ending March 6, 1869, was—on Monday, Tuesday, and Saturday (free) from 10 a.m. to 10 p.m., 12,598; Meyrick and other galleries, 2,724; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 5 p.m., 2,209; Meyrick and other galleries, 205; total, 17,736. Average of corresponding week in former years, 10,148. Total from opening of Museum, 8,210,860.

BARON VISCONTI has just discovered at Ostia a colossal head of Vespasian, and one of Trajan of the natural size. Both are in good preservation, and appear to have been buried by the friends of those of the Cosars that frequently took place after their downfall. An immense portice has also been excavated, which is supposed to have formed an entrance to the old plain of Cybele, outside the walls

IT appears that a proposal has been made to M. Boutet, the proprietor of the Channel bridge, to undertake the connection of the town of St. Malo with the French coast by a causeway or viaduct constructed on his system, and that the Anglo-French Ohannel Bridge Company are about to undertake this work. The town of St. Malo stands upon an island, distant from the mainland, with which, however, it is in some measure connected by a causeway, usually covered by the sea.

The value of the contributions to geological know-ledge through the researches of Mr. H. C. Sorby, F.R.S., has been publicly recognised by the Geological Society of London awarding him the Wollaston gold medal, in presenting which the President (Professor Huxley) stated that, in awarding it, the Council desired to testify their appreciation of the value which they, in common with all other geologists, attach to Mr. Sorby's laborious investigations, continued to the control of the co tinued now for a period of more than eighteen years.

In the month of August is to take place the first award of the great prize of 100,000 francs, instituted by the Emperor Napoleon III., to be voted by the Academy of the Beaux Arts and the Institute of France to the French artist, painter, sculptor, or

architect who shall have produced, and entirely completed within the five years preceding the time of the award, a work of great excellence. The jury is to consist of thirty members—ten sculptors, ten painters, and ten architects. In case any of the members of this jury should become candidates for the prize they will retire from it, and their places will be filled up by the Academy.

It was stated at a meeting of shareholders held a few days since, says the "City Press," that an offer of £7 per foot for a piece of ground in the neighbourhood of Smithfield-market had been reneighbourhood of Smithfield-market had been re-fused. This would certainly lead to the inference that land in the city is not decreasing in value, and therefore it is not to be wondered at that those who possess it should seek to turn it to account in the best possible way. It is said that the former play-ground of the Charterhouse will shortly be built on, and other improvements which are talked of in the neighbourhood will soon materially change the aspect of affairs in that locality.

WITHIN the last few days living specimens have WITHIN the last few days living specimens have been forwarded to this country from Nicaragua of one of the most gigantic plants in the vegetable kingdom. It is closely allied to the Arums (or "Lords and Ladies") of our hedges, and until the present time has wholly escaped the notice of travelling botanists. It produces but one leaf, nearly 14ft. in length, supported on a stalk 10ft long. The stem of the flower is a foot in circumference, the spathe or flower 2ft long, purplish blue in colour, with a powerful carrion like odour. As this remarkable species of Aroideen is quite new to science, it has not yet received a name. it has not yet received a name.

it has not yet received a name.

The value of the exports of glass beads from Verice during 1868 was as follows:—To Bombay, Calcutta, Singapore, to the value of 1,860,000 francs; England, 1,470,000 francs; Zanzibar and eastern coast of Africa, 659,000 francs; North America, 570,000 francs; Germany, Denmark, and Sweden, 560,000 francs; West Coast of Africa, 520,000 francs; France, Belgium, and Holland, 467,000 francs; South America, 430,000 francs; Constantinople and the Black Sea, 425,000 francs; Egypt, Tripoli, and Morocco, 375,000 francs; Russia, 280,000 francs; Italy, 78,000 francs; Spain and Portugal, 75,000 francs; Java and Sumatra, 70,000 francs; making a total value of 7,830,000 francs (£313,200).

(£313,200).

At the ordinary general meeting of the Royal Institute of British Architects, held on Monday, the stat March, 1869, the president (W. Tite, M.P.), in the chair, the following recommendations for membership were read:—Messrs. Elijah Hoole and George Scamell, as associates. The following gentlemen were then belloted for, and declared to be duly elected:—Mr. Alfred Strong (associate), as fellow; and Mr. William F. Williams, as associate. The president announced the recommendation of the council, that subject to Her Majesty's gracious sanction, the Royal Gold Medal for 1869 be awarded to Professor C. R. Lepsius, of Berlin, at the special general meeting, to be held on Monday, the 5th April next.

MR. SYKES'S Bill for the Preservation of Sea Birds, now in the House of Commons, proposes to enact penalties not exceeding 20s. (half to the informer, half to the credit of the county rate), with costs, on any person killing, wounding, or taking any sea bird, or using any instrument for so doing, or having in his control or possession any sea bird recently killed, wounded, or taken, between the 1st of May and the 1st of August, the breeding season. of May and the 1st of August, the breeding season. But the Bill is not to extend to sea birds taken bonafide for use as food. The offender refusing to give his real name and address to any person requiring it is to be liable to a further penalty not exceeding 40s., with costs. "Sea birds" are to be deemed to include the different species of gulls, hawks, guillemots, cormorants, puffins, terns, oyster-catchers, but have been season to discover better the content of th skuas, petrels, gannets, divers, razor-bills, shear-waters and grebes, merganser, eider ducks, and

# Patents for Inbentions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

2541 H. B. BINKO, Kingslam. Laundry indigo. Dated August 14, 1868.

August 14, 1868.

This consists in producing what the patentee calls "indigo carmine," carmine blue," and blue paper, in the following manner:—He takes 24th, fine indigo dissolved in 12th, strong oil of vitriol; this solution, when settled, is heated in a vessel containing twenty gallons of water and 1th, of cow hair. This mixture, when cold, is again heated, evaporated down to the consistency of pasts; the hair being removed, a thin solution of gum arabic and glycerine is added, and the mixture is allowed to settle. Sheets of paper may be dipped in the solution, and dried previous to being used.—Patent abandoned.

2542 W SHAFF Redford and Fariance and the strength of the solution.

2542 W. SHAEN, Bedford-row. Explosive compound. Dated ugust 14, 1868.

August 14, 1868.
The patentee combines with the explosive substance called wood gunpowder, the substance known as nitro-glycerine, the compound mixture is advantageously formed by mixing from 10b 4to 60lb, weight of nitro-glycerine with 100lb, of wood gunpowder, but the amount of nitro-glycerine will be varied according to the purpose for which the explosive compound is required.—Patent completed.

compound is required.—Patent completed.

2544 G. NRISON, Leeds. Disinfecting apparates. Dated August 14, 1868.

The patentee uses a double chest or box, rectangular in shape, and mounted upon supports. Across the top of the box are ranged (resting on a suitable framework) a series of adjustable from bars, upon which rests the articles to disinfected, when such articles consist of clothing or articles of a like nature. When flocks, feathers, bedding or small articles are to be disinfected, perforated iron trays or shelves resting on the aforesaid framework, are used to hold the same. Underneath the plate which forms the bottom of the box, means may be arranged of producing dry heat expeditionally.—Patent completed.

2545 J. B. THOMPSON, Horton, Bucks. Coating from and (cc). Dated August 14, 1868. This invention is fully described at page 176.

This invention is fully described at page 17s.

2546 W. E. NEWTON, Chancery-lane. Combing stit. Dated
August 15, 1868.

The object of this is to discharge or take off from the
combs or cards of combing machinery, the fibrous material
in a perfectly progressive and uniform manner. The
combs or cards are secured to an endless chain, atrap, or
apron, and are placed in an inclined position. They are
provided at each end with bowls or antifriction wheels,
which come into contact with curved guides or rails.—
Patent abandoned.

2547 J. MACINTOSH, Regent's Park. Telegraph lines. Dated

2:47 J. MACINTOSH, Regent's Park. Telegraph lines. Dated August 15, 1868.

This consists in dividing long submarine lines into sections, united by relays in conjunction with local batteries or induction coils (or simply by induction coils), these being enclosed within air and water-tight vessels, submerged together, and in conjunction with the cable at the bottom of the sea, the object being to obtain signals through long submarine telegraph lines with greater rapidity than heretofore, or, the speed being the same, with a reduction in the weight of materials in the core of the cable. The local battery or electromotor sending forward a fresh current, by the action of the relay, may consist of any voltaic battery of suitable construction (devised to remain in constant action for a considerable period of time), which, together with the relay, are enclosed with the air and water-tight vessel, which is furnished with earth contacts and stuffing boxes, through which latter the two ends of the cable pass, and are hermetically sealed; when induction coils are alone used, the cable is enlarged at the point of connection sufficiently to envelope the coil, which is submerged with the cable to the bottom.—Patent completed.

2:43 C. D. Abr. Chancerviane.

as anomerged with the cable to the bottom.—Fatent completed.

2548 C. D. ABEL, Chancery-lane. Printing. Deted August 15, 1868.

This consists in first mixing one part by weight of aloes with eight parts by weight of nitric acid of 30deg. Baume. The mixture is allowed to react, either in a cold or in a heated condition, after which, the product is saturated with slacked lime in fine powder, in the proportion of one part by weight of lime to four parts by weight of the extract.—Patent abandoned.

2549 J. FLETCHER, Salford. Grinding. Dated August 15.

1868.
This consists in supporting the revolving trough of mortar mills, or mills for grinding sandor other substances upon antifriction rollers, mounted on radial spokes, which rotate around the central axle of the mill, and in grinding the axle in a centre bearing. Another part of the invention consists in raising and lowering the grinding rollers simultaneously, by means of a cross shaft, with worms or wheels gearing into wheels, the bosses of which form nuts for screws, connected to the horizontal axle of the grinding rollers. These worm wheels are turned round alternately in one direction or the other, by a friction or other wheel on the driving shaft.—Patent completed.

wheel on the driving shaft.—Patent completed.

2550 J. Hickisson, Southgate-road. Marking peacil. Dated
August 15, 1868.

The patentee combines with nitrate or other suitable
salt of silver, blue, bone, ivory black, or composition
black, black or Italian chalk, gamboge, and gum arabic.
The proportions of the matters may be varied, but those
he has found to answer are:—Nitrate or other salt of silver,
los. 1 drachm; blue, or black, or chalk, jos. 1 drachm;

gamboge, 1½ scruple; gum arabic, 1½ scruple, mixed with distilled water. Ammonia, isinglass, perchloride or etheral solution of gold and milk of sulphur, may also be added.—Patent abandoned.

added.—Patent abandoned.

2551 R. ROBINSON and G. D. EDMESTON, Preston.

Lather. Dated August 15, 1868.

This consists in combining differential gearing to the face-plate of the lathe, which gearing is connected with a cone or other well-known motion for varying speeds. The mechanism for varying rotating speeds consist in combining differential gearing (either bevel or spur) with expanding cones or pulleys, so that these cones may be made to approach each other or be withdrawn one from the other, or be expanded or contracted while in motion by turning the differential gearing by hand or by self-acting mechanism.—Patent completed.

2552 A. J. LEAK, Stafford. Pottery machines. Dated August 15, 1868.

This relates to a peculiar and economical mode of driving or actuating "jiggers," "lathes," and "throwing wheels," whereby the long line of expensive shafting, with the numerous pulleys, &c., are dispensed with by the employment of endless chains gearing into chain pulleys or toothed wheels fast on the spindle or shaft which transmits motion to the particular machine required.—Patent shandoned.

abandoned.

2553 H. REISSMANN, Watling-street. Fountain. Dated August 15, 1868.

A hollow flexible vessel is formed of vulcanized indiarubber. This contains the liquid to be projected; the base of the vessel is attached to a button on a rod free to slide through a frame which is made in a piece with or supported by a pedestal or pillar. A to-and-fro motion is imparted to the rod by a lever or button, and when a lever is employed it passes through the pedestal; a nozzle is fitted to the top of the flexible vessel.—Patent abandoned.

to the top of the flexible vessel.—Patent abandoned.

2554 H. Y. D. Scott, Ealing. Pottery kilns. Dated Angust 15, 1868.

This consists, first, in giving the containing walls of the oven or kiln arched forms resting on immovable abutments or foundations instead of on vertical walls held together by fron bands, as is now practised. Second, in the introduction of air passages at different points in the length of the flues, so as to command the means of completing the combustion of the unburned combustible gases derived from the fires wherever heat is required for the complete firing of the goods. Third, in the employment of fireplaces adapted to the production of combustible gases, and the use of small or refuse coal and slack for the production of the gaseous fuel.—Patent completed.

2555 C. Mohr and S. E. Smith, Birmingham, Wire guards. Dated August 15, 1868.

The patentees employ moulds of any suitable description, in or across which the wires are laid, and molten metal, to form the bar or other connection, is then run into the mould upon and around the wires, thus securing the wires within the casting.—Patent abandoned.

wires within the casting.—Patent abandoned.

2556 A. M. CLARK, Chancery-lane. Site. Dated August 15, 1868.

The patentee places in an iron or copper boiler about 28 gallons of pure water, and adds about 8th. of salt of sods or other alkaline salt which dissolves by heat and agitation. About 900th. of resin is put in, in small quantities, leaving an interval of time between each addition to allow of the resin being thoroughly dissolved before adding a fresh quantity. After the whole has been mixed, the heating is discontinued. About 44th. of chlorided, the heating is discontinued. About 44th. of chlorided of the saline water, as above prepared, with about 30 gallons of cold water. The resin, while still hot, is then mixed together with half of the saline water, as above prepared, with about 30 gallons of cold water. The mixture is then heated and stirred with a spatula, so as to render it homogeneous, and assumes a deep wine colour. This change is produced by the union of the prepared resin and the salt. The mixture is then allowed to settle and form a deposit at the bottom of the vessel, the liquid part being decanted and discharged. The size or deposit thus produced is then ready for use.—Patent completed.

2557 J. H. DEARLE and T. BROWN, Piccadilly. Tests.

2557 J. H. DEARLE and T. BROWN, Piccadilly. Tents.

Dated August 15, 1868.

At the four corners of the ground which the tent is to At the four corners of the ground which the tent is to cover, staves or poles are erected, and the two staves or poles at each end lean in together and meet at the top. The canvas cover of the tent is placed over these staves or poles; the two extremities of the ridge of the roof are thus sustained, and the cover is kept distended along the ridge of the roof by two ropes, each of which is attached to the upper ends of one pair of the staves or poles, and extends to a peg driven into the ground beyond the end of the tent. The cover is held out at the bottom by the four staves or poles stepping into eyes formed in it at the corners. The side walls of the tent, that is to say, the theoriems of the cover extending from the ground to a height of 5ft. or 6ft., where the slope of the roof commences, are held upright by stretchers passing horizontally across the ends of the tent, and at each end entering an eye at the upper corner of the side wall; these stretchers may be simply straight staves, of a length equal to the width of the tent, but they may advantageously be provided with screws or other straining apparatus for distending the canvas.—Patent completed.

2556 W. B. Espuer, Jamacia. Extracting molasse.

2558 W. B. ESPUET, Jamacia. Extracting molasses.

2556 W. B. ERFURT, Jamacia. Extracting molasses.

Dated August 15, 1868.

The sugar to be operated on is placed upon a surface of wire gauze or other open material forming the bottom of a chamber which, when the sugar has been introduced, is closed airtight by a cover. Beneath this chamber there is a space in which a vacuum is produced by any means, and then the air enclosed in the upper chamber over the sugar forces its way downwards through the sugar into the vacuum space, and in so doing carries with it the moisture from the sugar.—Patent completed.

2559 W. T. Hung Burwash Sussey. Candie-bolders

2859 W. T. HINDE, Burwash, Sussex. Candle-holders.

Dated August 15, 1868.

The patentee employs a piece of cork or other material fitting the socket of the candlestick, with plates top and bottom, through which a pin or rivet is passed to hold them together.—Patent completed.

2560 A. SMITH, Glasgow. Sugar. Dated August 17, 1868.

This relates to the manufacture of sugar in improved modes, and by means of general arrangements or combinations of apparatus performing the same. The apparatus comprises a number of rectangular vessels or pans

set on two straight walls, and with the fire gases from one or more furnaces at one end passing lengthwise under and heating them. The bottoms of the pans are formed with corrugations to increase the heating surface, A channel is formed across the ends of the corrugations in order to completely drain or empty the corrugations when required.—Patent completed.

2561 E. BEANES, Maidenhead. Brewers' finings. Dated August 17, 1868.

This consists in neutralizing solutions of isingless in caustic alkalies by means of an acid sulphite or bisulphite of the base used for making the solution.—Patent aban-

2562 B. HUNT, Lincoln's Inn. Decomposing sulphurets of

2562 B. Hunt, Lincoln's Inn. Decomposing sulphurets of from. Dated August 17, 1868.
A cylinder is provided with movable covers at each end, and placed horizontally en a furnace of suitable construction, by which it is heated to, say, shout one-half of its length. This cylinder communicates with a pump by which air may be forced in to a pressure of, say, from two to four atmospheres, or when so required it may be connected with an ordinary boiler for the introduction of steam at the same pressure. The top of the cylinder is provided with valves of the section and charge required to maintain the pressure within, and to give issue to the products of the reaction, and to the surplus air or steam.—Patent completed.

Patent completed.

2563 B. P. STOCKMAN, Westminster. Water meters. Dated August 17, 1868.

This consists of two cylinders and pistons combined, and working with a reciprocating action, namely, one piston up while the other is down. The two cylinders are placed side by side on a base plate common to both. The pistons are packed with a cupped leather to ensure their working watertight. At the top of the cylinders there is a capping plate upon which is seated the whole system of gearing comprising the valve apparatus. Each piston has a toothed rack attached to it in place of a piston rod, and the two racks pass through holes provided for the purpose in the capping plate. Between the two racks is a toothed wheel in gear with both, and reciprocating their ascent and descent; on the same common centre with the wheel, but capable of turning partly round independently of it, are a weighted lever and a valve which alternates the peasages for the supply and discharge. From each cylinder there is a pipe communicating with the valve face, and two other pipes also communicating with the valve face.—Patent abandoned.

2564 W. E. Newton, Chancery-lane. Fog alarum.

valve face.—Patent abandoned.

2564 W. E. Newton, Chancery-lane. Fog alarum.
Dated August 17, 1868.

This consists in placing within a hollow cylinder a trumpet or horn, which is to be acted upon by compressed air through means of a hollow plunger fitted to work within the cylinder and hollow plunger, great compactness is given to the apparatus or device; a screw plug is attached to the body of the trumpet or horn for the easy removal of the reed when necessary to renew os repair it.

—Patent completed.

2565 J. PALMER, New Hampshire, United States. Carriage springs. Dated August 17, 1868.

This consists in constructing right-and-left dies for punching out ears in any required form or size to be fixed on the ends of the main leaf of an elliptic spring preparatory to welding, which greatly facilitates the making of heads to the same.—Patent completed.

2566 W. EDWARDS, Redditch. Sewing machine needles. Dated August 17, 1868.

Dated August 17, 1868.

The needle is made of a triangular flattened form resembling the blade of a pen-knife; the eye is formed through the widest section—that is to say, from the back to the edge, instead of making it across in the narrowest section, as hitherto, the groove for the sewing thread being formed in the thicker edge or back of the blade.—

Patent abandoned.

2567 T. H. JOHNSON, Lincoln's Inn. Cleaning grain.
Dated August 17, 1868.

A "smut" machine is provided with two stationary vertical hollow cylinders placed concentrically, in the inner one of which revolves a set of secouring beaters attached to a vertical shaft; the shaft carries near its upper end a revolving suction fan working in a chamber situate above the two cylinders aforesaid, and communicating therewith by a central mouth or opening. This chamber is provided with a discharge spout at its circumference, for the discharge of the currents of air produced by the fan along with the impurities removed from the grain by the scouring beaters. On rotating the main vertical shaft, a central draught of air from the bottom of the stationary cylinders is forced or drawn upwards through the inner casing or cylinder, enclosing the scouring beaters, and also between the casing and the outer casing or cylinder of the machine or mill. Both these upward currents of air unite in the chamber containing the fan before referred to, entering by the central mouth or opening in the bottom of such chamber, and passing out by the lateral spout or mouth.—Patent completed.

2568 E. F. Bradburg, Oldham. Seeing machines.

mouth.—Patent completed.

2568 E. F. Brandury, Oldham. Seeing mackines.
Dated August 17, 1868.
A segmental hook is caused to make a partial forward rotation so as to pass its point through the loop of the needle thread until its hook can catch the loop when it makes its back partial rotation, one side of the loop passing on the inner, the other side lof the loop on the outer side of 'the shuttle, the loop being taken by the hook past the lower part of the shuttle, so that it will draw freely from the shuttle, when the next loop is made, the notch in the cavity of the shuttle-holder preventing the back movement of the loop by the friction of the returning hook. The partial rotary motion of the segmental hook is produced by a toothed segment and pinion.—Patent completed.

2569 W. CORBITT, Botherham. Stove decorating. Dated August 16, 1868.
This consists in the employment of plates of steel or other metal having ornamental designs etched thereon for stoves, fenders, &c.—Patent completed.

2570 C. J., W., A., and F. SIMPSON, Preston. Drying yarn. Dated August 17, 1868.

This consists in placing an extra drying cylinder either above, below, or between troughs, so that the yarn, after it leaves the first trough, may be dried, or partially dried, by passing round the drying cylinder before it enters the second trough, where it receives an additional coat of

size. From this second trough, the yarn passes round the second drying cylinder situate at the end of the machine, and on leaving this cylinder it is guided by means of guide rollers over a revolving fan—Patent completed.

2571 A. ALBINI and J. VARLICIA, Broad-street. Electromagnets. Dated August 17, 1888.

The patentees connect the negative end of one coil with the negative end of the adjoining coil, and the positive of the one coil with the positive end of the other, by which means the current from one end of the battery enters both coils simultaneously, and leaves them also simultaneously.

—Patent abandoned.

2572 H. J. BEHRENS and E. DART. Paris. Rotary engines

2572 H. J. Beherns and E. Dart, Paris. Rolary enginese Dated August 17, 1868.

Two pistons are mounted on two parallel shafts geared together so as to revolve in contrary directions and at the same speeds; these pistons, segmental in form, revolve in two annular spaces in communication with one another, and the shafts are placed at such a distance that the naves forming the centre of the spaces are indented in such manner as to allow a passage to the other piston, which, being adjusted, prevents steam or other fluid from passing between it and the nave. When the machine is arranged to work as a motive power engine with steam, it acts alternately on each piston by acting on the circumference of the other, which is then drawn by the gearing, and their motion thus rendered uniform; and, when the same principle is applied to a pump, the vacuum is made by the displacement of each piston, which, at the same time that it allows a quantity of water to enter by one opening, causes a similar quantity to pass off or escape by another.—Patent completed.

2573 J. Phillips, South Hampstead. Stores. Dated

—Patent completed.

2573 J. PHILLIPS, South Hampstead. Stores. Dated August 17, 1868.

A cylindrical valve or damper in the flue is worked by a knob screwed into a rod attached to the valve. This is moved up and down in a vertical slot in the top front of the stove. This flue communicates at bottom with a passage leading from the back of the ash-pit. The space under the firebox is closed in front by a door or casing having a regulator fitted thereto for admitting air when necessary.—Patent abandoned.

necessary.—ratem abandonous.

2574 J. Bridgs, Kingsland-road. Cutting shives or bungs.

Dated August 18, 1868.

The cutter spindle is made in such a manner as only to be allowed to revolve, and not alide sideways or up and down.—Patent completed.

2575 J. G. TONGUE, Chancery-lane. Grinding mills. Dated August 18, 18

August 18, 1863.

This invention relates to mills for grinding grain or other substances in which three millstones are employed, one running and two standing, in such manner that the two surfaces of the running millstone act as working parts, and which are in contact with the surfaces of the standing millstones, through the eyes of which the grain or other substance to be ground is conducted. The stationary millstones are mounted in supports, which rest in guides formed in the base or foundation plate of the apparatus, and so that they can be caused to approach towards the running millstone in such manner that the positions of the working surfaces may be readily adjusted.—Patent completed.

2576 D. G. ETTGERALD Batterses. Volute Interv.

Dated August 18, 1868.

This consists in the insulation of a signalling current by means of good conductors of electricity (metals and electrolytes) so arranged as to generate an electromotive force which opposes the secape of the signalling current when the latter is transmitted in a particular direction.— Patent abandoned.

2577 J.T. STARNES, Ratcliff, Middlesex. Ships' lamps.

2577 J.T. STARNER, MANCHELL, MARCHELL, MARCHEL

parts, any one or two of which can be obscured at will by a shutter.—Patent completed.

2578 P. B. and W. Hoder, Adelphi. Pigments. Dated August 18, 1868.

For one form of pigment the patentees take a yellow, brown, or red ochre oxides, or protoxides, or peroxides, or seequaoxides of iron, or any of the alluminous earths wherein iron forms a portion of the compound, whether it be a chromate oxide, protoxide, peroxide, sesquaoxide, carbonate, sulphite, or sulphate of iron, and grind them to an impalpable powder; they are then washed and "slopped" in a vessel of any size required for the quantity. In another vessel of like kind they wash and "slop" highly carbonized peat, so as to deprive it of fibre and earthy matter. When both these "slops" are complete they are mixed together in an iron vessel with a fire underneath, at the same time a motion is kept up in the "slopped" material to prevent the heavier material separating from the lighter; and to ensure a proper commingling of the two materials, the fire and motion are kept up until the aqueous matter is nearly evaporated, when the "slopped" materials get to a consistency that separation is impossible. The materials so compounded are dried on a kiln, or any other suitable place. It is then placed into a close retort, either of clay or iron, and kept perfectly free from air, as the admission of oxygen would prevent the iron compound in the material from taking up the carbon. A fire is placed under the retort for the space of an hour or more, at a red heat, when the whole material is converted into a black pigment.—Patent completed.

2579 D.Fraser, Forfar. Spinning flax. Dated August 18, 1852

2579 D. FRASER, Forfar, Spinning flax, Dated August 18.

1868.
This consists, first, in softening the hard ends of flax by means of suitable apparatus, whereby the flax is made to yield more in the hackling, and to join better when being spun into yarns. It consists, second, in treating the tow in combined cramping and teasing apparatus, by which it is softened, mixed, damped, and teased. Steam is applied to the flax or rovings when spinning them.—Patent completed.

2580 J. LANDLESS, Manchester. Boilers. Dated August 18, 1868.

This comists in the construction of a damper or screen composed of wire perforated plates, made of earthenware or fireproof material, placed in flues, by which a more thorough combustion of the gases is effected.—Patent completed.

2581 E. LEDGER, Peckham. Motice pour August 18, 1868.

Angust 18, 1868.

A pump is connected with the cylinder of a hydraulic ram by a tube, so that on each depression and elevation of

the piston of the cylindrical pump there will be a corresponding elevation and depression of the ram in the hydraulic machine.—Patent abandoned.

2582 L. GAY, Rheims, France. Washing wool. Dated August 18, 1868.

August 18, 1868.

A conical vessel is employed to which a slow rotatory motion is imparted; this vessel is placed horizontally, or nearly so, its extremities are only partially closed; internally it is provided with a series of projecting hooks or points. The wool, or other fibrous material to be washed, is fed in at one of the extremities, and by the rotation of the appearius gradually conducted to the other extremity, from whence it is discharged; whilst the liquid used for washing is introduced at the extremity from which the wool is discharged, and drawn off at the extremity where the wool is discharged, and drawn off at the extremity where

the wool is introduced.—Patent completed.

2583 W. THOMSON, Glasgow. Cutting tool. Dated August 18, 1868.

The tool or instrument is composed of a body piece, to which expanding comes are fastened, their ends being held in dovetailed slots in the face of the body, so that they may be free to move in a radial direction to and from the central part of the expander. Through the body of the expander a spindle passes, one end of which is provided with tapor grooves to receive the expanding comes, the other end of the spindle is screwed, so that by tightening the nut thereon against the body, the inner tapered surfaces are drawn against the inner side of the tube or ring to be expanded, and, when sufficiently tightened, the expander is rotated within the ring or tube, by which action it is expanded equally at all points.—Patent completed.

2584 E. DEANE, London Bridge. Cooking store. Dated August 19, 1868.

The patentee does not describe any construction of store.—Patent abandoned.

the patentee does not describe any construction of stove.—Patent abandoned.

2585 J. Newmann, Bedford-square. Gas apparatus. Dated Angust 19, 1868.

This consists in adapting a retort to domestic or kitchen stoves; besides the retort there is a gas washer and purifier, with a receptacle to receive the coal tar in combination with a gas-holder fitted in the ordinary manner in a water tank.—Patent abandoned.

2586 J. H. ATTERBURY, York. Earthenvare machinery. Dated August 19, 1868.

Upon a suitable iron foundation plate the patentee mounts two vertical metal standards opposite to each other, and furnished with planed surfaces on their inner sides in the centre portion of their length. On the top of the standards a horizontal shaft is mounted, on which an eccentric is placed that it is free to work between the standards, and is connected by means of a strap and rod with a crosshead to which it imparts a reciprocating movement, the crosshead being guided by the planed surface referred to. To the underside of the orosahead a die is fitted of the size and shape which it is desired to impress on the plastic material to be operated upon. This die may be heated.—Patent completed.

2587 J. Norberry and J. Shaw, Salford. Force pumps.

2587 J. NORBURY and J. SHAW, Salford. Force pumps. Dated August 19, 1868.
This consists in fitting the cupped leather on the plunger instead of in the barrel.—Patent abandoned.

instead of in the barrel.—Patent abandoned.

2688 F. Braby, Camberwell. Treating sulphate of iron. Dated August 19, 1868.

According to the first method, the patentee adds ammonia derived from any source to the waste product above mentioned, until complets decomposition takes place, by blowing air through a solution of ammonia, and then conducting the blast loaded with the volatile alkali through the solution to be decomposed. The results of this decomposition are oxide of iron, which falls, and must be washed and dried at a low red heat for commercial uses, and sulphate of ammonia, which must be filtered, boiled down, and crystallized. Secondly, he adds carbonate of ammonia or blows carbonic acid and ammonicacl gases through the crude solution of sulphate of iron. The results of decomposition in this case are carbonate of iron and sulphate of ammonia. Thirdly, he neutralizes the crude solution of sulphate of iron by adding thereto scrap iron or finely powdered oxide of iron, and boiling or digesting the same at a low temperature. The solution is mixed with a solution and the salt of the parts lime or lead, whereby useful results are obtained, the sulphate being precipitated, and the salt of iron, as the chloride acetate or other compound, remaining in solution.—Patent completed.

2589 A. CLARK, Chancery-lane. Tanning leather. Dated

2589 A. CLARK, Chancery-lane. Tanning leather. Dated

2869 A. CLARK, Chancery-lane. Tanning leather. Dated August 19, 1868.

This consists of a combination of catechu, or cutch, with common lye in various proportions. This mixture may be used alone or with a colouring matter such as alum, and with salt, or other material that will serve to plump the leather if so desired.—Patent completed.

the leather if so desired.—Favent completed.

2590 W. H. DAYRY, Caledonian-road. Drying Linen.
Dated August 19, 1868:

The apparatus is composed of two steam chests placed
in a horizontal and parallel position, one above the other,
on a suitable framing, a space being left between the
steam chests for the passage of an endless chain or apron
passing over a drum, upon which is placed the linen
fabrics or substances to be dried.—Patent abandoned.

2591 J. Heaton, Derby. Rails. Dated August 19, 1868. This consists in combining a steel or wrought-iron rail forming the wheel-bearing surface of the compound rail with wrought-iron bars, rolled of such a form as to fit accurately against the opposite sides of the web of the steel rail, and, at the same time, form a base or flat bottom flange for resting upon the sleepers. The two wrought-iron bars are bolted or riveted firmly together so as hold or grip the web of the steel rail securely between them.—Patent abandoned.

2592 T. R. Shaw Pandleton Oli Interes Dated

Patent shandoned.

2692 T. R. SHAW, Pendleton. Oil testers. Dated August 20, 1868.

On a vertical shaft fitted in bearings is fixed a disc, on the upper surface of which rests a circular or partiy circular block, the two surfaces in contact being preferably finished as true plans. The lower disc is caused to revolve rapidly by suitable means, the continued rotation of the block being prevented by a cord, one end of which is attached to the side of the block, the other end being attached to the side of the block, the other end being attached to a spring balance or to a weighted and gradual lever. The block is kept in position on the revolving disc by means of anti-friction bowls, which are so applied as not to interfere with the rotation of the block. A they momitted is fixed in the centre of the block. A smell portion

of the lubricant to be tested is applied to the disc, the metal block is placed in position, and the lower disc is caused to revolve until a certain temperature, which has been fixed upon as suitable for all seasons as, for example, 70deg. Fah. is indicated by the thermometer when the test of the oil is commenced, by noting the frictional resistance indicated on the scale of the spring balance, readings being taken from the scale at intervals during the continuance of the experiment.—Patent completed.

continuance of the experiment.—Patent completed.

2593 W. J. Almond, Cheapside. Preparing silk. Dated.
August 20, 1868.

The thread from the swifts or bobbins are wound into balls with a hollow centre, in such a way that the inside end of the thread may be drawn out with perfect order and freedom until the whole of the thread in the ball is used. This ball is placed in a box of cardboard, paper, or other suitable material, wherein it is secured in such a manner as to remain without any fastening. In the front, or one side of the box, is fitted an eyelet or perforation through which the thread may run freely without being injured by friction.—Patent completed.

2594 J. Sawyer New North-road Subse. Dated

2594 J. Sawyer, New North-road, Sashes.
August 20, 1868.
Window seebes are constructed with related

August 20, 1868.
Window sashes are constructed with rebated joints at the part where the two sashes meet together when shut for the purposes of better excluding the air, rain, and wind. The window sashes have metal plates with teeth or cogs on one side thereof (or formed with indentures or slots) forming racks. These racks are of the same length as the height of the sashes, and are let into grooves or rebated in the sides or edges thereof flush therewith; or they may form projections thereout for the purpose of hanging or suspending the window sashes.—Patent completed.

2535 G. CALKIN, Regent's Park, Taching music. Dated

suspending the window asshes.—Patent completed.

2595 G. Calkin, Regent's Park. Teaching music. Dated August 20, 1868.

The object is to designate by a ready means to the student the character and position of each note on the key-board. A diagram of the key-board, or any part thereof, is constructed in the form of a long flat rail or ledge, which is placed in front of the keys is such a position below them as not to interfere with the playing, and so that each key on the diagram shall be exactly opposite the corresponding key of the instrument.—Patent abandoned.

doned.

2596 H. N. WATERS, Connecticut, U.S.A. Steam generators. Dated August 20, 1868.

This consists in heating the water which is intended to be pumped into the steam generator up to the boiling temperature, or nearly so, with the exhaust steam from the engine, and, at the same time, separating the sediment and floating impurities which it may contain. This is accomplished by means of a cylinder, into which the exhaust steam passes by a tube; a shield is fitted on the top of the cylinder for the steam to impinge against. Cold water is admitted by a pipe leading into the cylinder.—Patent completed. -Patent completed.

2597 P. ROBERTSON, Mincing lane. Brake. Dated August 20, 1868.

The patentee connects to any brake, by a flexible tube, a vessel containing dried sand, so that the sand may be ad-mitted through an aperture in the brake to act upon the wheel.—Patent abandoned.

wheel.—Patent abandoned.

2598 A. ROLLASON, Commercial-road. Purifying gas.
Dated August 20, 1868.

The patentee takes peat, bog, or other similar decomposed vegetable matter, and, having disintegrated it, mixes with it sulphuric acid of the specific gravity of 1840 or 1848, in about the proportion of one part of the latter to two or three parts of the former; if the decomposed vegetable matter requires to be artificially dried before the sold is added, care must be taken not to burn or char it. The product is designed to be used in an ordinary gas purifying box apart from the other purifying boxes, and the gas should pass through it first after it leaves the scrubber, so that any ammonia which the scrubber has failed to work out of the gas is arrested as it passes through it forming sulphate of ammonia.—Patent completed.

2599 H. Hughes, Homerton. Seving machines. Dated

work out of the gas is arrested as it passes unuequent forming sulphate of ammonia.—Patent completed.

2599 H. Hughes, Homerton. Sewing machines. Dated August 20, 1868.

The patentee employs a series of horizontal or inclined plates or pin projections carried by an endless chain, to which an intermittent motion is imparted by a paul from the ordinary feed motion. This endless chain is secured to the work plate, and in its intermittent motion the series of plates necessarily take against the thread, when the needle is at the upper part of its motion, and thereby effect the intermittent feed of the fabric; these plates at the same time receive the whole strain of the stitch, because, after each intermittent movement, the needle, in its down stroke, lays the thread over that plate which has just acted upon the thread. In some cases came are employed on the chain to act on a lever carrying an additional or separate thread, cord, tape, or piping, in such manner that the lever lays this separate thread, oord, tape, or piping on the two sides of the needle thread alternately, whereby a variety in the work is produced.—Patent completed.

2600 H. C. Eusell, St. Helen's. Smelting. Dated

a variety in the work is produced.—Patent completed.

2600 H. C. EUSBLI., St. Helen's. Smelting. Dated August 20, 1868.

Gaseous fuel is passed through tubes or conduits, which can be heated so as to heat the gaseous fuel. By means of other tubes or conduits, nitrous gas, or exygen, or atmospheric air, either combined or separately, and either hot or cold, can be mixed with the gaseous fuel. The air and gases are introduced into the furnace, either at atmospheric air, either contained into the furnace, either at atmospheric pressure or at a pressure higher than that of the atmosphere, by means of fans or other blowing apparatus. The pipes or conduits are provided with dampers or valves, by means of which the quantity of gases or vapours and the temperature of the same may be regulated at pleasure. By the combustion of the gaseous mixture described an intense heat is produced, the combustion being effected in the reverberatory furnace in which the copper ore to be smelted is contained. The vapours and gases from the smelting furnace descend into a covered space containing a layer or layers of peroxide of iron in the state of bog iron or bog ochre, or in any other convenient form, together with haryta or other absorbent substance, according to the nature of the gases and vapours given off by the furnace.—Patent completed.

2601 N. W. NEWTON, Chancery-lane. Rotary engines. This invention mainly has reference to that class of rotary engines which employ a revolving piston, made up of or carrying radial slides, and that, together with the main or diving shaft to which it is secured, occupy, an eccentric position relatively to the cylinder in which the

piston works, and consists in the employment of steam or other impelling fluid by, in, or through an arrangement of cylinders, the one within the other; firstly, using such gas, vapour, or fluid at a high pressure on a short piston leverage, and subsequently working the same under expansion and at a reduced pressure on a long piston leverage. The invention also consists in a combination of parts and disposition of ports for thus using the steam, whereby the piston itself or radial slides thereof serve without it may be, the aid of valves, to control, not only the exhaust or final escape of the impelling fluid, but also its passage, after being utilized in a high pressure form to work expansively in a separate cylinder, upon or in connection with one and the same piston.—Patent completed.

with one and the same piston.—Patent completed.

2602 T. HAIGHT, Liverpool. Cooling liquids. Dated August 21, 1863.

The patentee takes any number of pipes, covered externally with a coating of tin, and "sweated" together in line parallel to each other; each end of these tubes are fitted into a metal casting, which is of a square or other analagous form; these castings form hollow boxes or chambers into which the ends of the pipes open, the same being divided by transverse disphragms, so arranged that the water or other cooling liquid, being at the lower end of the first chamber, will pass through the lower pipe or tube, and thence into the chamber in the casting at the opposite end of the tube, into which the lower and next tube immediately above opens, so that the water may return through the second pipe, in an opposite direction, into a chamber in the first-named casting; and so on through the series of pipes.—Patent completed.

2603 J. ELLIOTT, Southampton. Cutting stons. Dated

2603 J. Elliott, Southampton. Cutting stone. Dated

2003 J. ELLIOTT, SOULDAMPRON. Cutting time. Dated August 21, 1868.
This consists in a tool composed of a holder and a diamond or steel cutter, being caused to revolve rapidly on its own axis, and to traverse in any direction required over the surface of stone, or other hard substance to be out.—Patent abandoned.

2604 E. J. E. Niepce, Paris. Horse' blinkers. Dated August 21, 1868.

These blinkers are provided with mechanism, in connection with a bellows, expanding cap, or obturator, which it keeps constantly closed within the blinker, unless the driver. by pulling a rein attached to the mechanism, causes the obturator to open, when it completely covers the horse's eyeball, totally depriving it of sight, and causing the horse to stop; upon abandoning the rein the obturator closes again, and the horse recovers sight.—Patent completed. nleted.

2605 J. H. JOHNSON, Lincoln's Inn. Flour mills. Dated

2605 J. H. JOHNSON, Lincoln's Inn. Flour mills. Dated August 21, 1868.

A pipe leads from the closed casing of the millstones downwards to an exhausting fan. The flour and meel are timmediately blown up a vertical pipe into a hopper, the top of which is covered by a frame of gauze. The air escapes through the gauze, whilst the flour and meal is deposited in the hopper, and descends thence by the discharge spout into the "bolt."—Patent abandoned.

charge spout into the "bota — rate and another."

2606 P. N. HASLUCK, Tottenham Court-road. Discerning indicator. Dated August 21, 1868.

A stud is placed in the stock of the carriage wheel, each revolution of the wheel communicates a blow to a survivel of four pinions. Each revolution of the star wheel drives a wheel of eighty-eight teeth, and thus indicates on a dial the 1,760 yards (or one mile).—Patent abandoned.

a dial the 1,760 yards (or one mile).—Patent abandoned.

2607 F. J. KNEWSTUB, St. James's-street. Despatch
boxes, &c. Dated August 21, 1868.

This consists, first, in fitting despatch boxes at their
upper part with one or more sliding trays, which can be
made to slide entirely or partly out at the end or ends of
the box when the lid is raised. Second, in providing in a
space underneath the sliding tray or trays, leaves
arranged alphabetically or numerically, for the purpose of
allowing instant reference to papers or other articles
placed in such leaves; these leaves may either be fixtures
in an inside frame or tied in through eyelet holes, so as to
be moved at pleasure.—Patent completed.

be moved at pleasure.—Patent completed.

2608 T. W. RAMMELL, Westminster. Rotary engines
Dated August 21, 1868.

This consists in gradually reducing the size of the
radiating ducts or passages from the mouths outwards.
This reduction is made in such manner that while at their
junction with the central apertures, that is to say, at their
mouths, the ducts are collectively equal in transverse area
to the sum of the areas of the two apertures, they become
gradually smaller and smaller in proportion as they extend
outwards, and are smallest where they terminate in their
discharge outlets at the rim or periphery of the machine.

—Patent completed.

—Patent completed.

2609 J. L. CLARK, Sydenham. Train communication.
Dated August 21, 1868.

A tube is employed, extending from end to end of the train, and contains air, which is either exhausted or compressed by means of a pump worked from the axles of the tender or engine. A bell or other sounding apparatus is fixed upon the engine or tender, and in each of the guard's vans, and is so arranged as to sound incessantly as long as the train is in motion, the power for working the apparatus being taken from the wheels or springs, or other moving parts of the train. The apparatus is, however, further arranged in such manner that whenever the vacuum or pressure is maintained by the pump or bellows, the bell or sounding apparatus is silenced, either by its being thrown out of geur, or by the hammer being removed and held out of its reach.—Patent completed.

2810 B. WALKER and T. F. A. PELAUM, Loeds. Rolling

removed and held out of its reach.—Patent completed.

2610 B. WALKER and T. F. A. PFLAUM, Leeds. Rolling tyres. Dated August 21, 1868.

Two main spindles are employed, to which a pair of rollers are fixed; these run in bearings in strong framings mounted on centres, through which the driving shafts run; these shafts may be driven in any suitable manner. The centres are carried by slides capable of sliding to and from one another, from the bed of the machine, so that by bringing the slides close up to one another, the spindles may both be brought into a vertical position; or by separating the slides, they may each be made to incline one towards the other. The upper ends of the frames carrying the rolls may be drawn together by mechanism, so as to give the requisite pressure. The main spindles can be made to work at different angles and to move to or fro at either end, simultaneously or separately, as may be required. If it be required to work the machine for rolling disc wheels, the spindles are made to incline to one smother.—Patent completed.

2411 D. Evers, Hackney. Casts. Dated August 21, 1462.
This consists in making metallic vessels or casks of a square or other shape, by fixing the blank on a mandril of square form.—Patent completed.

2613 J. Tall, Southwark. Building walls. Dat news 31, 1888.

Arrust 1, 1868.

The object is to dispense with angle or ceraer pieces, and also with the upright parting pieces to which the long panels of the apparatus are attached, and also to simplify the fastenings whereby the several parts of the apparatus are connected together; and, further, to construct the panels in such a manner that they may be lengthened or shortened, as may be required to suit circumstances. This is accomplished by fixing the panels by means of bolts passing through tubes; the corners are composed of plates fastened to the panels in a similar manner.—Patent completed. complete

2813 J. WRISLEY and J. HOLDING, Lancaster. Looms. Dated August 22, 1868.

The first part relating to the "healds" consists in knitting them in fine wire and yarn, the top being composed of wire and the bottom of yarn. Also, in making the bottom of top heald, stave, or both of them square or other suitable form, to one side of which the knitted portion of the heald is secured. The second part relates to temples, and consists, first, in using but one roller of larger diameter than usual, the periphery of which is provided with metal pins for holding the cloth. The roller forms a loose box, which, as the cloth passes over it, freely revolves upon a fixed pin, retained in the box or under portion of the temple; the cap of the temple, being formed adjustable, is so arranged that it can be I owered so as to cause the cloth to press well upon and nearly embrace the upper half of the loose box, or it may be raised and secured so as only lightly to press thereupon.—Patent completed.

completed.

2614 A. B. CHILDS, Mark-lane. Cutting millitones. Dated August 22, 1868.

This consists chiefly in giving to the diamond tool or cutting points a peculiar compound motion, and also in the devices for producing such motion in combination with the devices for holding the diamond, and for moving the same in the required direction over the face of the stone.

—Patent abandoned.

Patent shandoned.

2615 W. J. and C. A. KESSELMEYER, Manchester Engine governors, Dated August 22, 1868.

The patentees connect a vessel or vessels containing a fluid to a movable part of the governor; there is also another vessel or vessels containing fluid communicating with that, or those first mentioned. As the balls rise or fall, the fluid passes from one vessel to another until a common level is attained, and the balls therefore become less or more loaded. The vessels which contain the fluid have curved interior surfaces, whereby the quantity of fluid is in proportion to every position of the balls.—Patent completed.

2616 T. M. B. Errtram, Ludgate-hill. Illuminated signs.
Dated August 22, 1868.
The pateness proposes to form the device in platinum,
after the measur of a stendil plate, and to attach the same
to a gas burner in such a manner that when the gas is
lighted the platinum will become heated by the fiame, and
present a highly illuminated surface.—Patent completed.

2617 J. WATSON, Sunderland. Hast furnaces. Dated

Angust 22, 1868.

This consists in making the interior of the furnace of various widths, by forming a series of tapers. In order to obtain a hot blast, the patentee directs the products of a bottler farnace through a flue in which air tubes are placed, leading from a blast engine, so that the air becomes heated in its passage.—Patent completed.

2618 E. D. MORGAN, Tyn-y-coed, Rbyl, Flintshire.

Sustamning apparatus. Dated Angust 22, 1868.

This consists in constructing a glove or apparatus for facilitating awimming, by providing webs between all the fingers, and between the first flager and thumb.—Patent abandoned.

2619 G. H. Barrer. Southerman

2619 G. H. BARBER, Southampton. Preserving me.
Dated Angust 22, 1888.
The patentee constructs a flexible air-tight bag
receptacle, and in this he places the meat to be preserve.
The bag is placed in a box or case having open trays
perforated partitions therein.—Patent abandoned.

2620 H. THOMPSON, Islington. Roughing horses. Dated ugust 22, 1868.

August 22, 1868.
This consists in fitting in the hollow or inner edges of
This consists in fitting in the hollow or inner edges of
shoes a triangular socket in which acrew rods can be
shoes a triangular socket in which acrew rods, carry hooks,
placed, the outer ends of the screw rods, carry hooks,
clips, or abutments, upon which the roughing spikes are
clips, or abutments, upon which the roughing spikes are
clips, or abutments, upon which the roughing spikes are
clips, or abutments, upon which the roughing spikes are

Dated — Patent completed.

2621 W. R. LAKE, Chancery-lane. Uniting railed railed August 22, 1868.

This consists in applying springs or yielding substances to fish bers of railway rails, to compensate for the expansion and contraction of the rails, and at the same time to absorb all the vibration occasioned by the wheels of a passing train.—Patent completed.

Passing train—Patent completed.

2622 W. J. Sallett, Leeds. Gravitating wheel engine.

A hollow disc is mounted upon a drum (fitted with an Anoster ring), in which a hole is made for the reception of a sanety eccentrically with the disc, and in the line of the horizontal axis of the same. Upon the inner end of the shaft, and within the disc drum, a boss is keyed, groved diagonally, say, at eight different points on its face, for the reception of sliding bars, to the outer ends of which are connected friction pulleys, which work between the peripherty of the disc drum and the inner ring.—Patent abandoned.

2623 W. CHORLTON Mandanta.

2623 W. CHORLTON, Manchester. Heald-scarpers. Dated rune 24, 1863.
The beams supporting the unsized or untreated warps the beams supporting the unsized or untreated warps the beams at the delivery end of the machine, or at the framing, at the delivery end of the machine, or at the framing, at the delivery end of the machine, or at the stand where the unprepared warps are first placed on the "tape leg" or "slashing" machine, or in the ordinary rangement in the rote of the property of the beams are prevented from revolving too freely by means of springs or weights the came each beam or roller revolves, and delivers its yarn, and delivers the delivers of the free the delivery of the part of the place.

2624 C. George, Dulwich. Artificial horizon. Dated

2624 C. GEORGE, Dulwich. Aristical sortion. Date:
August 24, 1863.
The instrument is made of two circular metal reservoirs.
The instrument is made of two circular metal reservoirs or trays, preferably formed in one casting, the one contains of the supply of mercury, and the other, which is used for observations, being provided with a glass cap or cover. These reservoirs communicate with each other by a narrow neck on their circumference, provided with a through channel, having a stop cock for regulating the passage of the mercury from one reservoir to the other, without requiring to remove the glass cover, or risk the loss of any mercury. The mercury reservoir is further provided with a spring valve or stopper to admit air or allow of its escape.—Patent abandoned.

2625 G. TIDCOMBE, Herts. Boot scraper. Dated August 24,

1868.

The patentee forms a surface of iron, steel, or other metal, by preference cast, and of trellis or other form, producing retioulate or cellular openings or open chambers, with the upper edges of the form adopted sharper than the under surface. They are applied to rest on a floor or other surface, or over a recess, or pit, or in a box prepared for them to receive the dirt thus removed.—Patent completed.

2626 A. F. ECKHARDT, Hamburg. Masuring grain. Dated August 24, 1868.

This consists in manuring and covering seeds and roots with a covering or case insoluble in water, the manure is thus retained in contact with the peeds or roots during the growth of the plant.—Patent completed.

the growth of the plant.—Patent completed.

2637 A. GODMAN, Newcastle. Furnacci. Dated August 24, 1868.

This consists in the employment of fire-bars, which are caused to vibrate vertically at the front end on a fulcrum, situate at or near their inner ends, such vibratory motion being imparted to them by means of a series of tappets or wipers adjusted on a transverse revolving shaft. The surface of each fire-bar is notched or corrugated, and are so combined and arranged as by their simple vertical movement to impel forward the full as fast as it is sllowed to enter thereon.—Patent abandoned.

2628 W. B. LARE Charcerslane. Contrides.

enter thereon.—Patent abundoned.

2628 W. R. LAKE, Chancery-lane. Cartridges. Dated August 24, 1868.

The rear end or base is formed solidly with the tube or cylindrical part of the shell, the interior corner or angle, at the junction of the base and cylindrical portion, being allied up with the solid metal, by curving or hevilling, the surface of the tube to meet the interior of the base. At the contre of the inside of the base, and in the solid metal of the same, a cup or cavity is formed with a raised flange to receive the fulminate, this flange may be either flattened over the fulminate to form the anvil, or may be turned over the fulminate to form the anvil, or may be part of the same and over the fulminate to form the anvil, or may be surred over upon a separate disc employed for that purpose.—Patent abandoned.

Patent abandoned.

2630 W. H. TOQTH, Greenwich. Bricks, &c. Dated August 24, 1868.

The patentee employs gravel, broken stone, or other bard material, containing a proportion of iron; this is wetted with a solution of sods or other alkall, together with a small quantity of sal ammoniac. The addition of a with a small quantity of sal ammoniac. The addition of a little sulphur in powder will quicken the esting of the ingredients, as it will act on the iron, and will develop heat. When well mixed, the ingredients may be moulded and pressed.—Patent abandoned.

2631 G 3 Coulse Bardoned.

2631 G. J. Collerge, High Holborn. Need's holders. Date August 24, 1868.
A holder or protector for sewing needles is composed

August 24, 1868.

A holder or protector for sewing needles is composed of two caps of 'twey, hard wood, or other material; to the edge of each cap three elastic bands are attached, the hands pass from one cap to the other, and serves to connect them together.—Patent abandoned.

nect them together.—Patent abandoued.

2632 G. S. Dragofulo, Cardiff. Forcing states. Dated August 24, 1863.

The apparatus consists of a metal tube, closed at the top, and of any length and diameter required, at the bottom of and of any length and diameter required, when it immersed in water at the bottom of a ship's hold or elsewhere. Above the inlet of water a tube is brought from an air pump or other machine for compressing air, to a jacket or casing surrounding the receptacle by which means the water is suddenly forced or expelled up the tube to the deck, and escapes by an exit pipe, whence it is conveyed away. Another supply of water then rushes into the receptacles or reservoir, and is in turn raised up the tube, and carried of by the impetus or rush of sir.—Patent completed.

2623 H. GROUND, Norwich. Bushing bung holes. Dated

2632 H. GROUND, Norwich. Bushing bung holes. Dated August 24, 1868.

A metal bush of iron is employed, consisting of a tube of a length exceeding the thickness of the stave to which it is to be applied. This tube has a flange at one end to rest against the face of the stave; the tube is formed to secure a seat for the stave or bung. The bush is placed in the hole formed for it in the stave, and then, by driving in a conical tool, the inner or unflanged end of the bush, which then projects through the stave, is expanded or opened out, so as to prevent the bush being again drawn out of the bush.—Patent completed.

2634 I Jeavons and C. Martin. Sheffield. Ship's plat-

the hole.—Patent completed.

2634 J. Jeavons and C. Martin, Sheffield. Ship's plating. Dated August 25, 1868.

Iron of any of the ordinary English brands is employed, refined or non-refined siliceous iron is taken and combined with titanic iron, obtained from ittaniferous ores (such for instance as ilmenite) in the puddling furnace, and afterwards piled in the ordinary manner, until the necessary degree of fibrous structure is produced, the plates being rolled in the usual manner.—Patent completed.

2635 R. COUCHMAN, Noble-street, London. Dre

Dated August 25, 1868.
This consists in so forming the front part of a button, atunder similar dress fastening of oval or oblong stud, or other similar dress fastening of oval or oblong form.—Patent abandoned.

2636 R. SCHOLEFIELD, Leeds. Brick machinery. Dated

2636 R. SCHOLEFIELD, Leeds. Brice machinery. Dates August 25, 1863.
This consists, firstly, in a circular disc, in which are a This consists, firstly, in a circular disc, in which are a series of moulds or recesses of suitable form for the clay or plastic material to be moulded in. This disc is mounted horizontally upon a series of friction rollers, and is capable of rotating on a central pillar, fixed upon a suitable bed plate. To the outer edge of the disc on the top side is fixed a rim or flauge projecting upward, which, with the disc, forms a hopper to receive the supply of clay, and to the under side or to the edge of the disc is formed or attached a toothed wheel, in which a pinion gears for giving motion thereto. One or more rollers are mounted on arms affixed to the pillar above the disc, to which rollers

by preference an intermittent rotary motion is given by star wheel; or a continuous rotary motion may be given to them so as to roll upon and press the clay into the moulds as the disc rotates under them.—Patent completed.

to them so as to roll upon and press the cisy into the moulds as the disc rotates under them.—Patent completed, 2637 C.J. B. Jahns, Liverpool. Obtaining power. Detect Aurust 28, 1868.

This consists in mechanism for using the power of water or vapour moving through a flexible pipe for acting as a rotary engine. The patentee constructs a parify cylindrical box having two nozzles or short pipes placed in the interior. There are three rollers of elastic scoutchous, which, at equal distances apart, are pivotted to two parallel discs connected to each other by a central shaft or axis, having one end passing through the centre of the box, and the other end working on a centre, or having both ends passing through the sides of the box. These discs revolve in the interior of the box, so that the rollers, when passing the circular periphery, may be always at equal distances from the centre, and roll on the flexible pipe which lies between them and the circular periphery. The diameters of the rollers are such that they will be slightly pressed when rolling on the fiexible tube.—Patent abandoned.

2638 W.C. Camberdes. Crushing sett. Dated August 25,

2638 W.C. CAMBRIDGE. Crushing soil. Dated August 25,

1868.

This consists in fitting a projecting rib on the rim of the wheels of the "Cambridge Clod Crusher." The improvement in barrows consists in making some of the links wider than the others.—Patent abandoned.

wider than the others.—Patent abandoned.

2639 B. J. COMEN, Hamburg. Memorandum tablet. Dated August 25, 1868.

This consists of a slate tablet or sheet fitted in a case or box, one end of the case being open to allow passage to the slate, and one of the sides being formed internally with ratchet teeth or notohes. This side can be moved outwards, when required, on a hinge or pin, but is held in place by a lock operated by a key. The side of the slate or tablet is fitted with a spring or paul to take into the ratchet teeth.—Patent completed.

2640 I. S. Angorg Rirmingham. Account books. Dated

ratchet teeth.—Patent completed.

2640 J. S. Adcock, Birmingham. Account books. Dated
August 25, 1868.

The patentee makes the journal a record of every transaction of the husiness, the journal being of itself a cash
book, a bill book, a purchase and sales book, and a disbook and is, with the exception of a ledger, the only
book necessary for keeping accounts.—Patent abandoned.

book necessary for keeping accounts.—Patent abandoned.

2641 J. Barrans. Leeds. Flattening pin and needle heads.

Dated Aurust 25, 1868.

Upon a wiltishle frame the patentee mounts a horisontal
double cranked shaft, and be connects to such cranks vertical sliding bars, to the lower ends of which adjustable jaws
are fitted capable of holding die stampers or flatteners. On
the bottom of the frame are also mounted adjustable anvils
underneath the stampers or flatteners. The crank shaft
being set in motion by a driving pulley apon one end of it,
the relative position of the die stampers and anvils are
regulated according to the required thickness of the
article to be flattened.—Patent abandoned.

2042 J. I. LOSS. Glassow. Biedleg timber. Dated

regulated according to the required thickness of the article to be flattened.—Patent abandoned.

2042 J. L. Lose, G. aggow. Bioding strates. Dated Angust 25, 1868.

The lors or beams of timber to be reduced from the rough dimensions are laid upon a travelling bed, above the bed a box is placed carrying one or more knives, so the bed a box is placed carrying one or more knives, so a reciprocating vertical movement is also imparted to the box carrying the knife or knives, so that in the downward stroke the knife or knives cut into the timber to any required length that the machine may be set to cut. The required length that the machine may be set to cut. The substitution of the horizontally, whils the splints or satipa are cross cut by a vertical cutter actually at the end and in front of the horizontal knife. When one part of the surface operated upon is thus treated, the table is traversed forward to bring a new part of the surface under the cutters, and it is similarly treated.—Patent completed.

2613 J. GILLOTT and P. COPLRY, York. Coal cutting. Dated August 25, 1868.

The patentese employ a horizontal revolving wheel or this having a series of cutters mounts in the veriphery thereof, such cutters being made to cut outwards or from the bottom of the groove or undercut to the face of the working, whilst the body of the machine itself takes its bearing against the face in order to resist the strain of the cut. In some cases guide rails may be employed. The whole is mounted on a suitable carriage made sufficiently low to admit of the cutters getting well down to to the bottom of the face for the purpose of "holing in the bottom when required.—Patent completed.

2641 J. H. Johnson, Lincoln's Inn. Condensing. Dated August 25, 1863.

August 25, 1863.

This consists in carrying off the heat from the refrigerating water or liquid as fast as it is imparted thereto, by lowing or otherwise passing cold atmospheric air through it.—Patent completed.

2645 A. M. CLARE, Chancery-lane. Brechlosds.
Date: August 28, 1868.
This consists of a short tube, made to lift out of its ple
in the end of the barrel, for the insertion of the obar
and then lowered into position so as to close the breePatent completed.

Patent completed.

2646 R. HARVEY, Bristol. Seeing machines. Dated August 25, 1868.

A bar or lever is employed which has its fulcrum on a stud, one end of the lever being forked to embrace an eccentric, which is fastened to a shaft mounted in bearings, whereby, as the eccentric rotates, it will impart a reciprocating motion to the ends of the bar or lever, and thus cause the shattle or needle, or other part operated on to travel to and fro in its race.—Patent completed.

2617 A E ROSENE Scathing lang London.

to travel to and fro in its race.—Patent completed.

2617 A. E. Boren, Scething-lane, London. Decomposing
faity bodies. Dated August 25, 1863.

According to this invention the fatty substances are
melted and treated mechanically with sulphuric acid of
66deg. to 63deg. Beaume, more or less, after which they
are boiled with water, by which the oxide of glyceryl is
separated therefrom, in a hydrated form, as glyceryl water
or sulphate of glyceryl.—Patent abandoned.

676 J. Loader, Upper Clifton-street, Worship-square, Middlesex. Improvements in rotary engines and pumps.

677 R. Badger, Sawbridgeworth, Hertfordshire. Improvements in shears and scissors.

678 W. S. Meldrum, Leeds. Improvements in carding engines for flax, tow, hemp, jute, wool, and other fibrous substances.

679 J. B. Spence, Manchester. Improvements in the production of substances to be used in the purification of illuminating gas, and in the recovery of a waste product arising threader or instrument for threading needles.

680 A. Morrall, Studley, Warwickshire. An improved needle threader or instrument for threading needles.

681 T. Ross, jun., Glasgow. Improvements in sildes for magic lanterns, which improvements are also applicable for other purposes.

682 H. and J. Ellis, Salford. Improvements in cranes for raising merchandise and weights of all descriptions.

683 W. G. Simon, Oakley-square, Middlesex. An improved hank for hoisting and lowering fore and aft salls, which invention may also be applied to cranes and other hoisting apparatus, and to reducing friction.

684 R. R. Bevis, Birkenhead. Improvements in screw propellers.

propellers.
685 A. M. Clark, Chancery-lane. Improvements in envelopes, and in the means employed for securing their contents.

685 A. M. Clark, Chancery-lane. Improvements in envelopes, and in the means employed for securing their contents.

Dated March 8, 1869.

636 A. Dixon, Railway-Jace, Fenchurch-street, City. Improvements in steam lubricators or greasers.

637 J. A. M'Elroy, Glasgow. Improvements in rotory motive-power pumping and measuring apparatus.

638 J. B. Roweliffe, Manchester. Improvements in the manufacture of wire cloth for paper-making machines.

639 W. Burr, King Edward-street, City. Improvements in the manufacture of compressed leather.

630 W. A. Gilbee, South-street, Finsbury. An improved apparatus for raising water.

631 J. J. E. and W. Pitt, Cleckheaton, Yorkshire. Improvements in machinery or apparatus for drilling, turning, or cutting and shaping metals or other materials.

632 C. Mather and W. Rossetter, Salford. Improvements in warping and weaving machine.

633 C. Fairbairn, Marion Villa Sciennes, Edinburgh. Improvements in the construction of furnaces.

634 L. M. Ruiz, Rue d'Antin, Paris. Improvements in purifying and clarifying all sorts of oils, whether mineral, vegetable, or animal.

635 H. Taylor, Queen-street, Cheapside, City. Improvements in the construction of spring bottoms for bedsteads, couches, and scats.

636 P. Buchan, Silver Stream, Green Island, near Belfast, and A. Guld, Belfast. Improvements in preparing for spinning jute and other vegetable fibres.

637 J. A. Jaques and J. A. Fanshawe, Tottenham, and J. T. Oakley, Grange-road, Bermondsey. Improvements in machines for grinding and surfacing rings, plates, discs, and other analogous articles made of iron or steel.

698 H. W. Cook, Ovington-square, Middlesex. An improved mode or modes of, and apparatus for, regulating clocks.

699 J. P. Budd, Ystabyfers, near Swanses. Improvements in the manufacture of iron and steel.

clocks, P. Budd, Ystabyfera, near Swansea. Improve-ments in the manufacture of iron and steel. 700 R. F. Pittz and T. H. Lee, Newnham-street, Edge-ware-road. Improvements in the manufacture of paper-

ware-road. Improvements in the manufacture of paper-hangings.
701 R. Turnbull and J. G. Piton, Cowper's-court, Corn-hill, City. Improved means and apparatus for signalling from one part of a railway train to another, the same being adaptable to warming purposes, and to signalling in ships or vessels, buildings, and other places.
702 T. Baker, Buckingham Villas, Stratford. Improvements in umbrellas, sunshades, and parasols.
703 W. B. Thompson, Dundee. Improvements in finishing textile fabrics, and in the machinery or apparatus employed therefor.
704 A. Mitchell, Leith. Improvements in cutting or dressing stone, and in the machinery or apparatus employed therefor.
705 W. Saunders and C. Smith, Newgate-street, City. An improved detachable standard board frame for dressing bags.
706 W. Saunders and C. Smith, Newgate-street, City.

ing bags.
706 W. Saunders and C. Smith, Newgate-street, City,
An improved combined chess and cribbage board or table.

#### MECHANICS' MAGAZINE.

LONDON: FRIDAY, MARCH 19, 1869.

# HYDROGEN AS AN ILLUMINATING

N every process, chemical or mechanical, a certain amount of loss or waste of either material or power must take place. results obtained by a chemical process never coincide exactly with the theoretical formula, nor, mechanically, can the work done, ever equal the power applied. An ignorance, or, what is worse, a culpable neglect of these fundamental principles, has led scientific fanatics to spend their time, money, and ultimately their lives, in a fruitless search after the impossible. The loss accruing to ordinary gas, from the very commencement of its manufacture, to the moment that it flows from the burners, as a source of illumination, is occasioned by both chemical and mechanical unavoidable imperfections. The latter is caused by leakage, owing chiefly to defective joints, unsound pipes, and the carelessness of those who are concerned in its manipulation and distribution. The former is due to chemical action solely, and could scarcely be prevented, which is not the case with the other sources of loss. About 14 per cent. may be taken as the average loss incurred in the manufacture and burning of ordinary gas, or that which represents the actual discrepancy between the theoretical and practical results. The composition of ordinary gas consists mainly of carburetted hydrogen gases; and as hydrogen itself possesses no power whatever of illumination or brilliancy, it is not, at first sight, quite obvious what advantage results from its presence. Anyone who has dabbled in elementary chemistry is aware that hydrogen gas, when tolerably pure, burns with a pale blue flame, emitting little or no light, but endowed with a very high temperature. At the same time, by causing its high temperature to act upon other bodies, such as platinum and lime, it developes a flame of great beauty and brilliancy. To a similar cause is due the illuminating properties of ordinary gas. The action of the high temperature of the burning hydrogen upon infinitesimal particles of carbon renders them incandescent, and imparts to the gas its powers of illumination. Hydrogen, therefore, destitute of brilliancy when pure, becomes possessed of that property when in mechanical combination with carbon; in other words, when it is carburetted. If it were possible to bestow upon hydrogen illuminating properties without carburetting it, as in the ordinary manufacture, the whole process would be rendered much simpler and more economical.

It has been asserted that it would be found a great advantage to employ a much larger proportion of hydrogen in the ordinary gas than what at present prevails; in fact, to constitute it rather a hydrogen gas than that of which it is now composed. A very large proportion of hydrogen is lost in the manufacturing process, which might be easily preserved and utilized, resulting in the production of a gas of a superior quality. The same may be stated with respect to other volatile and illuminating ingredients, including the paraffin and benzine, which, for the most part, are left in the bye products. Were hydrogen more carefully sought for, and preserved in the manufacture of gas, the volume would be considerably increased, in addition to a greater purity being imparted extensions, to the product. It is notorious that the undertaken. ordinary gas, in many of the smaller towns,

is so impure, and possessed of so small an illuminating power, that many persons refuse to have it laid on to their premises. composed mainly of hydrogen would be free from most of the noxious and disagreeable properties unquestionably possessed by our present great source of public illumination, but until it can be demonstrated that a better gas can be supplied at the same rate, we shall, as usual in such matters, stick to the old plan of manufacture.

#### THE DIRECT ENGLISH, AND AUSTRALIAN SUBMARINE TELEGRAPH COMPANY.

T is but a few weeks since our readers were advised of the formation of a company for extending our communication to India; and, again, this week, we have to announce the prospectus of a second company for somewhat similar objects, but with this difference: the previous company—the British Indian—promoted a scheme, an extension of successfully accomplished enterprises; the object of the present company is to strike out a line for themselves, and, as is stated, "to lay and work submarine telegraphs between England, Gibraltar, Malta, Egypt, India, China, and Australia, which shall be in English hands from end to end." As a special recommendation, it is further stated that the cable intended for this route will be little more than half that of the ordinary deep-sea cables, and "it is at the same time safer, both for laying and picking up, and quite equal for endurance". This special quite equal for endurance. This special cable has been experimented upon by Sir W. Thomson and Mr. Varley (who are the consulting electrician and electrical engineer to the company), and the results are stated to be most satisfactory, although no mention whatever is made in the prospectus as to what sort of cable has been specially selected. The capital of the company is £2,500,000, in £5 shares, and the first issue will be £750,000. The report states that "with a view of ensuring direct and advantageous communication with the continent of Europe, it is proposed to lay at once a short line between Malta and Brindisi. The contractors will engage to ship this cable not later than the end of May," and that "the directors reserve to themselves to decide whether, after this branch line is laid, a cable from Malta to Egypt, or from Suez to Bombay, shall be next laid." Malta is certainly an important station to our country, and has been, to our knowledge, in direct and advantageous communication with the Continent and with England for many years, and how the proposed cable from Malta to Brindisi is to improve that communication, we are at a loss to see; and, further, how the laying of this cable reconciles itself with the objects of the company, of having a direct submarine line in English hands, from England to India, is a

mystery to us.
On the success of this short cable it is a question for the directors to decide whether to lay a cable from Malta to Egypt or from Suez to Bombay. In the former case, a cable would be laid between two points where and working already we have two existing cables; in the second case, a cable would be laid where one is about to be laid, the British Indian Company, we lately alluded to, having contracted for the making of a cable and its submergence in the early part of next year. In either case, the intention of the directors would appear to be a direct opposition. This is most unfortunate. Submarine lines have hitherto been laid in connection with each other, and for the general public good. Extensions, by means of submarine cables, are costly undertakings, taking them at the cheapest, and it is strange that, in face of many useful and profitable extensions, such direct opposition should be

Australia are most important, and it is equally desirable that they should be in our We cordially agree with the statehands. ment of the directors relative to the objects of the company, but it is a source of regret that they do not at once endeavour to carry out their object. Their object is to place England in direct submarine telegraph communication with Gibraltar, Malta, Egypt, India, China, and Australia; and with such an object in view, we would wish them every success. Let us take a glance of how our communication at present stands. We have communication at present stands. We have two good cables from Malta to Egypt, one already contracted for from Suez to Aden and Bombay; that is the middle of the chain. Let the new company first make and lay their cable from India to China and to Australia. This would be completed in the spring, at the same time as the British Indian line to Bombay. We should then have communication with our colonies through the agency of the several companies and the continental system, on the successful completion and satisfactory working of these lines; then the cables might be laid from England to Gibraltar and Malta, and we should possess a very great desideratum, the means of communicating direct by a system from end to end entirely in English hands.

With such splendid objects in view, meeting unquestionably with the support and approval of the other companies interested, we cannot conceive how the present company have determined upon the step of laying one cable which we cannot see the advantage of, and others in direct opposition to existing cables.

Provisional contracts have been entered into with the India-rubber, Gutta-percha, Telegraph Works Company, for the and making and laying the necessary cables, the company being satisfied that the contractors have in stock sufficient gutta-percha to insulate the whole contemplated line; and from our knowledge of the contractors, we doubt not that they will be well able to undertake and carry out the necessary contracts.

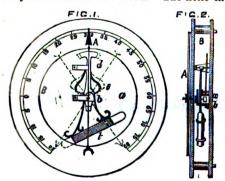

#### THE DETERMINATION OF ATMO-SPHERICAL VARIATIONS.

WING principally to the labours of the late Admiral Fitzroy, Mr. Glaisher, and other scientific and philosophical authorities, the subject of meteorology has within the last few years received an amount of thorough investigation and attention never previously bestowed upon it. In intimate connection with this vast and comprehensive science, are the instruments employed for the purpose of recording the necessary observations which serve as data for all future meteorological calculations. As may be readily imagined, these are both numerous and various, are constructed with the greatest skill and mechanical delicacy, and require to be manipulated with exceeding precision and gentleness. A visit to the Royal Observatory, and an inspection of the instruments used there for observing the occurrence of atmospheric phenomena-ordinary and extraordinary. -will amply repay any one who is ordinary—will amply repay any one who is interested in this important branch of philo-sophical study. All these instruments and apparatus may be included under two classifications. The one class are based upon physical, and the other upon chemical principles; and in some instances the two are combined in the same instrument. In all cases, the end in view is the same, namely, to record or register, and to estimate or measure, the variable conditions of the terrestrial atmosphere. To render this subject more attractive to the public, and the means of ascertaining what is commonly termed "what the weather is going to be," with greater facility, an instrument is required more ndertaken. simple in its construction, more general in Our communications to India, China, and its results, and cheaper in price than those

which are to be found in observatories and lecture rooms. The principal data needed, in order to permit any one to venture a guess at the weather, especially in so uncertain and changeable a climate as our own, are the temperature, the pressure, and the hygrometric state of the atmosphere. In other words, a combination of the thermometer, barometer, and hygrometer would compose an instrument affording the means of acting truly as a "weather glass." Comparatively speaking, it is only recently that the necessity of combining the observations recorded by these three separate instruments, in order to arrive at any accurate knowledge of the state of the atmosphere, has been recognized. They were originally regarded as having distinct offices, altogether independent of each other, and the observations recorded by the one were never imagined to bear any relation to those registered by the other. This view of the subject has fortunately yielded to the invincible power of science and experiment, and it is now well known that the observations of one are of little real value unless compared with those of the

A somewhat novel principle of constructing a true "weather glass" has been proposed by M. Bertora, of Paris. He suspends a tube, filled with mercury or other liquid, in a manner so that it changes its position or angle of inclination with the slightest variation either in the temperature or pressure of the atmosphere. So much for the abstract principle. Let us examine a little into the modus operandi. Take a glass tube, similar to an ordinary mercurial thermometer, but instead of having a bulb at one end, uniform in diameter throughout its entire length. Let it be partially filled with mercury, hermetically closed at both ends, and suspended in an inclined position between two oints, which maintain it in perfect equilibrium. At any given temperature, the small tube will rest at an angle of inclination determined by the position of its centre of gravity. If this temperature change from any cause whatever, manifestly the angle of inclination will undergo a corresponding variation, and it will be readily perceived that by the addition of a needle, a divided circle, and a delicate and simple combination of levers, these variations of the angle of inclination of the tube can be accurately registered, and consequently the atmo-spherical changes of which they are the tangible evidences.

In all instruments of this nature, the first step in their construction is to graduate them, and to fix two determinate points, marking respectively the maximum and minimum registrations, and the limits of the capabilities of the apparatus. These limits must necessarily be sufficiently wide apart These limits to admit of their including not only the ordinary but the extraordinary observations they are intended to record. The little in-

strument to which we at present allude is represented in figs. 1 and 2, and is almost self explanatory. The tube t is suspended at x. The upper portion of this support is geared into a small pinion d, the axis of which carries the sector c, which, in its turn, acts upon the central pinion b, and by means interferes seriously with their action. Never-

of its axis motion is imparted to the indicating needle A. The slightest movement of the mercury within the tube causes a change in the position of the centre of gravity, sets the sectors in motion, and, by means of the needle, registers upon the divided circle B the amount of the variation. M. Bertora considers that in accordance with this principle, thermometers, as well as barometers, might be constructed upon a large scale, so that the variations either of temperature or pressure might be rendered very appreciable, almost in a similar manner as the hours upon the face of a clock. By employing a couple of tubes, all the advantages belonging to the hygrometer might be obtained, by placing in one of them an absorbent body, and from a comparison of their relative results, deducing the hygrometric state of the air. There also appears to be no reason why pyrometers should not be constructed upon the same principle, and high temperatures accurately ascertained by its means. The determination, with any degree of accuracy, of high temperatures, has long been an unsolved problem, although there are not wanting many and various pyrometrical instruments designed solely for that purpose.

#### THE ROYAL INSTITUTION.

AST week, the Tuesday morning lecture was delivered by the Rev. F. W. Farrar, F.R.S., on "Comparative Philology." On this occasion, he spoke chiefly of the Semitic languages, of which the mother speech was probably Egyptian or Coptic. The Hebrew and the Arabic were the chief branches of the Semitic family, and all the languages of the family differ totally from the Aryan languages in structure, so that it is quite impossible that Greek, Latin, or any great European tongue, could have been derived from the Hebrew. The Hebrews do not add additional syllables to their words to change the meanings, but the consonants are always the same, and the meaning of the word is changed by altering the vowels between the consonants, so that the language is very hard and in-flexible, and quite unfitted for a scientific people. The Semitic languages are all dying out, and the Semitic races have always declined wherever they came into contact with the Aryans.

On Thursday, Dr. H. Power lectured upon the "Eye." He began with the amœboid or lowest form of sarcodic animals, revealed by the microscope, which have no eyes. worms and the rest of their family have no eyes, because eyes would be unnecessary luxuries to animals which live in darkness, and have a plentiful supply of food in contact with their mouths. Oysters have very good eyes, and plenty of them, all arranged in the fringe near the edge of the shell, so that directly any foreign substance tries to float in, the shell is abruptly closed. Snails have eyes at the tops of their horns, and when any object is placed across the path of a snail, the horns will be seen bending about to let the eyes survey the obstruction. Some of the living forms which inhabit the sea have eyes all along their sides, some have their eyes in their brain, and some again in the tips of their tails, so that they can see better behind than they can before. The dragon fly has than they can before. about 28,000 eyes.

On Friday evening, Professor Abel, F.R.S., of Woolwich Arsenal, gave a lecture before a large audience, upon "Some Applications of Electricity to Military and Naval Purposes," more especially to the firing of mines. He said that the galvanic battery is bad for such purposes, because it varies in power, is difficult to carry, and is very uncertain in action when many fuses have to be fired. Frictional electricity has been tried for the explosion of fuses, but the machines must be very carefully protected from the weather, as damp

theless, the Austrians have brought such machines to a great state of perfection, by enclosing them in cases of different kinds, but the best frictional machine to fire mines is a small one with two cylinders of india-rubber, and it will work well in damp weather. Hydro-electric machines are too much affected by the weather, and are heavy to carry. Magneto-electricity from large permanent magnets has been found to be uncertain in firing gunpowder, but the difficulty was surmounted, to a great extent, by the construction of very sensitive fuses, containing phosphide of copper, sulphide of copper, and chlorate of potash. With such fuses, magneto-electricity answered, and mines have even been fired by the small machines sold in the shops for medical purposes. Electricity of high tension will not do for submarine purposes. The dynamo-electric machines, recently introduced, have been found very good for warlike purposes, especially those machines which are strong and simple in construction, so as to be little liable to get out of order. They have the fault, that the currents from them act so powerfully by induction upon neighbouring wires, that the operator may fire one or two other mines, in addition to the one which he intended to explode. As regards torpedoes or submarine mines, electricity of low tension must be used, and galvanic electricity is best for the purpose.

Torpedoes which are fired by mechanical action, caused by contact with the bottom of a ship, are, when once laid, dangerous alike to friend and foe, and after the American war did much unexpected mischief in the harbours. A better plan is to fire them by electricity from the shore, and this is done by placing two operators at some little distance from each other, near the banks of the river or the sea beach, so that by concerted signals, they may know when a ship is passing over a torpedo, and then fire the mine. The trustworthiness and coolness of the operator is a great element in obtaining the desired results by the foregoing method. Perhaps the best way of firing torpedoes, is by means of a battery on shore, the circuit being completed by the mechanical action produced by contact with the bottom of the ship. The lecture was illustrated by numerous experiments.

On Saturday, Dr. William Odling, F.R.S., in his ninth lecture upon "Hydrogen and its Analogues," began by speaking of the "unburning" of hydrogen, and the separation of the gas from its compounds. He showed how sodium will separate the hydrogen from water with great energy, and that magnesium will do the same, but with less force; the water must be boiling, before magnesium will liberate the hydrogen from water freely. Zinc is much slower in its action than magnesium. Dr. Odling said that these methods of pulling the hydrogen away from the oxygen of water may be compared to the pulling away of a weight from the floor, by means of a greater weight connected with the smaller one, by a pulley. But as by a jerk or sudden application of direct force, a weight may be raised from the floor to the ceiling, so hydrogen may be separated from oxygen in a curious way by direct action. He illustrated this by raising a platinum ball almost to its melting point, by the heat of an oxyhydrogen flame, and then the white hot ball was suddenly placed beneath an inverted test tube full of water. This caused not only an ebullition of steam, but of a few bubbles of mixed oxygen and hydrogen gases, resulting from the de-composition of the steam by the intense heat.

#### SAFETY NITRO-GLYCERINE.

NEW method of protecting nitro-glycerine, and rendering it harmless, except under the conditions of actual work, has been invented by Mr. John Horsley, F.C.S., with whose explosive powder our readers are doubtless familiar in connection with Captain Harvey's torpedo. This new

combination was first exhibited by Mr. Horsley at a conversazione held last month in the Town Hall, Cheltenham, in connection with the Whitworth School of Science. Upon that occasion, Mr. Horsley gave a short lecture, with experiments, on explosive compounds, at the close of which he retired with several gentlemen to an adjoining lawn for the purpose of testing his newly-invented powder, for such we understand it to be. He loosely laid an ounce of it on a wrought-iron plate, a quarter of an inch thick, and exploded it by a peculiar process. The result was a terrific report, the iron plate being completely shattered. On his return, he showed the plate to the audience, who were greatly astonished at the force of the explosion, and remarks were made as to the security of our ironclads against such enormous power if developed by a torpedo. We are not in possession of the particulars of Mr. Horsley's method of treating the nitro-glycerine, which is not yet patented, but we are informed that the process is thoroughly successful. The inventor has entirely succeeded in rendering nitro-glycerine perfectly harmless and inexplosive till required for use, however severe the treatment to which it may be subjected. At any time its properties can be restored unimpaired for the use of the miner. Horsley sends us the following as proved tests of its safety:-1st. It will not ignite or explode on the application of fire or heat. 2nd. It cannot be exploded by a blow on an anvil. 3rd. It cannot be exploded by a percussion cap fired in a charge of it. As already observed, we are not in the secret of the invention, and therefore can only speak as to the proved results. These are certainly very remarkable; but we do not see anything more astonishing in them than in those attending the firing of dynamite. The new compound can only be exploded in one particular way; dynamite is in the same category. Both substances are also perfectly harmless until exploded by special and extraordinary means. We of course give Mr. Horsley every credit for his ingenuity in thus taming nitro-glycerine, but, as the case now stands before us, it is purely experimental, and we cannot discover in the new compound any superiority over dynamite.

#### NOTICES OF BOOKS.

T the close of the American war, Mr. James B. Eads, an American engineer and shipbuilder, was commissioned to examine the naval constructions of Europe, and to report thereon to the Secretary of the United States Navy. The result of Mr. Eads' investigations were embodied in a report\* to the Naval Secretary, and a copy of which has just reached us. In this document, after touching generally upon the question of naval construction, and paying a well-merited com-pliment to Mr. E. J. Reed, our Chief Con-structor, in respect of the "Bellerophon," the author goes on to criticise the turret question. He does not agree with the idea of cutting down the sides of the vessel-as in the Monitor system—to the lowest possible points compatible with flotation. The sad loss of life which has occurred from the rapid foundering of some of these vessels has taught a practical lesson of the folly of carrying this feature to too great an extent. The revolving turret is next unfavourably criticised; the author considering that it must be superseded by a system in which au equal number of guns can be protected with an equal economy of iron in a fixed casemate. The gist of the report is the publication of the author's designs for ships having from one to five fixed turrets within which the

gun-platform revolves. Here the whole battery is made to command the entire horizon, and can be brought to bear upon the same object through ports as small as the monitors, and be manipulated with equal ease and reliability. Mr. Eads of course falls foul of Captain Coles and Captain Ericsson, considering the deck joint a radical defect. He enters into the details of the proposed construction, giving a series of well-executed engravings, illustrative of the working of the system. On the whole, the "report" is not system. On the whole, the report what we expected to find it, considering its title. It is true the author submits it as result of his observations abroad," but having been commissioned "to examine the naval constructions of Europe," we should have expected something more than a little generalising about European turret ships-which could be done by the author in his own office—and a great deal of particularising about his own scheme. We do not, of course, object to inventors adopting the best means they can to publish their inventions, but we do not look for their publication in a report on the naval constructions of Europe.

The sixth annual volume of "Engineering Facts and Figures "\* is now us, and we are glad to say is no whit behind its predecessors. We need hardly state that the object of the work is to present a register of the progress in mechanical engineering and construction during each year. It is in part compiled from the MECHANICS' MAGAZINE and other scientific publications, with due acknowledgments. A leading feature in the present volume is a notice of the International Maritime Exhibition, held at Havre last year, and which was specially visited for the purposes of the work. Some additional notes are given on the Exhibition held in Paris, in 1867, which tend to complete the subjects discussed in the previous volume. The matter is, as usual, arranged and classified under distinctive headings, and thus we have boilers and boiler explosions, furnaces, fuel, and smoke prevention. The sixth division relates to steam engines; then follow in order locomotive engines, marine engines, and machinery in general. The tenth and two following divisions are devoted respectively to metals, railways, and ships. Of course there is not room for everything in such a volume, and those who expect to find it will be very properly disappointed. But the selection of matter is admirably made, and the most important points of the various subjects are given, reference being made to the work from which the information is obtained, as a guide to the reader, should he desire further details. The volume is amply illustrated, and is got up in the usual neat

Mr. Bourne's work+ on modern engines continues to be favourably received by, and to be regularly supplied to scientific readers. Parts VIII., IX., and X. are now before us, and are as full of interest as ever. In the three parts now to hand the author enters upon a description of various kinds of mill engines, marine engines, and locomotive engines, engravings and particulars of a great number of the latter being given. The plates are illustrative of steam winches, marine boilers, and marine engines, and there is an interesting appendix containing particulars of Morton's jet condenser.

We have also received Parts XI. and XII. of Mr. Burgh's treatise on the screw propeller,‡ in which we have a description of the feathering screw propeller, by Messrs. Maudslay, Sons, and Field. After this follows a description of the various arrangements for

feathering the blades of screw propellers, which have been proposed from time to time since the introduction of the screw. chapter is by Mr. Burgh, and extends nearly through the two parts. Chapter XVI. is devoted to a description of modern examples of thrust blocks, as fitted to screw propeller shafting, by the most eminent marine en-gineers of England and Scotland. Besides numerous wood engravings, we have folding plates, showing various screw propellers, holding down gear, hoisting apparatus, &c., as adopted in recent practice.

Mr. George Rickard has written a little

work, which will prove very interesting, as well as useful, to those who are unacquainted with the mysteries of mining, and who may desire to obtain a knowledge of the subject. The author first opens up the geological aspect of the subject, after which he views the question mineralogically, and enlightens outsiders upon the mysteries of mining terms. We then have the mechanical details of a mine explained, and are afterwards familiarised Subsequently with underground workings. to the methods of obtaining the ore, come the methods of dressing it, or preparing it for the market. This information is succeeded by some useful and practical remarks upon mining and mining companies, the whole forming a very useful little volume to the uninitiated in these matters.

The question of communication between the passengers and guards in railway trains has been solved by many minds in various ways, not so frequently to the satisfaction of others as of themselves. The American system of open trains has had many advocates, and the latest is Mr. George Lansdown, who, in a pamphlett recently forwarded to us, proposes the adoption of this method of personal communication as a remedy for the evil the recent act of Parliament seeks to meet. After considering the necessity for this means of communication, the author goes on to describe his patented method of connecting railway carriages by means of an adjustable gangway. This arrangement gangway. affords a clear passage throughout the length of a train of carriages of the present construction, although at the sacrifice of several seats in each carriage, which the alteration would involve. Of course, in new carriages, the seats might be differently arranged. It appears that a travelling post office on the London and North-Western Railway has been fitted on Mr. Lansdown's principle, and is now working in the Irish mail between London and Holyhead. There appears to be no difficulty in carrying out the scheme except that of reducing the number of seats —a difficulty we fear Mr. Lansdown will find rather insurmountable with railway directors

in the present day. The unsatisfactory condition of railway investments has induced Mr. John Imray to propose a method of improving their condi-tion. In a pamphlet! lately published, he proposes by one measure to effect two very important objects. He advocates cheap and uniform fares, which would prove a great boon to the public, whilst, in such a step, he sees as a further result not only increased but guaranteed dividends. The proposition and the arguments by which it is supported are well worthy the attention of those interested in railways, either as investors or as managers. We understand an association has been formed for the purpose of investigating the questions of railway fares, traffic, and manage ment, and we ask at their hands a quiet hearing for our author and his proposals.

NOTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

THE STRUCTURE OF PRECIOUS STONES.

TERY few persons who admire or who deal in precious stones are acquainted with the intimate structure of these valuable minerals; and most persons will be astonished to learn that these bodies, apparently so solid and homogeneous, are often full of minute cavities, which, in general, enclose a liquid. The examination of this structure and of the included fluid must necessarily teach us much relating to the origin and formation of the minerals, and is, therefore, of great interest to us. Fortunately, the subject has been taken up by Mr. Sorby, whose remarkable researches on anhydrous fluoric acid we recently noticed; and, from his well-known skill in both physical and chemical investigations, we may naturally expect most valuable results. Mr. Sorby was fortunate in having the interesting collection of Mr. Butler placed in his hands for examination, and it is from a paper produced by these two gentlemen conjointly that we gather the following particulars. Sapphires, it would seem, in general contain fluid cavities. Sir David Brewster met with one no less than the third of an inch long, but our authors have seen none more than one-tenth of an inch in diameter. These are usually half filled with a mobile and highly expansible liquid, which, as will be seen further on, is considered to be liquid carbonic acid. Sapphires, as our readers well know, are composed of pure alumina, coloured, it is generally admitted, by a metallic oxide; but, according to Kühlmann, if we remember rightly, by some organic matter. Now, if it be clearly established that the enclosed liquid is carbonic acid, some light is thrown upon the chemical reactions and physical condi-tions by which the stone is formed. The ruby is tions by which the stone is formed. also coloured alumina. Cavities, we are told, are far less numerous in these than in sapphires, and, moreover, they appear to contain only water or a moreover, they appear to contain only water saline solution. Occasionally, a liquid with similar characters to that observed in sapphires, is seen but not often; and we are thus led to suppose that the stone may be produced by different reactions and under different physical conditions.

The cavities in spinel, another form of alumina, are partly filled with a solid or very viscous liquid, and a colourless liquid of singular properties. It seems, says our author, to contract on the application of heat, and, in passing into vapour, must expand about 600 times less than when water passes into steam. No conjecture is offered as to what this liquid may be. Emeralds are often full of cavities which contain a liquid which does not expand when heated, and is apparently a strong aqueous saline solution. The emerald is a double silicate of alumina and glucina, and the liquid may be the mother liquor from which the emerald has crystallized. Our conjecture is supported by the fact that the cavities also contain crystals, which dissolve on the application of heat, and recrystallize on cooling.

The diamond is, of course, the most interesting of all our precious stones, the origin and mode of formation of which has always been a great puzzle to chemists and mineralogists. Its structure has already been studied by Göppert, who discovered what he conceived to be organic remains, and hence infers that the diamond is the result of vegetable decomposition under peculiar conditions. Sir David Brewster first noticed fluid cavities in the diamond, and explained the optical peculiarities of some diamonds by their prosence. Messrs. Sorby and Butler, however, show, that besides fluid cavities, diamonds sometimes enclose minute crystals of a different mineral, to which circumstance these owe their peculiar optical properties. In the diamond also, the enclosed liquid appears to be carbonic acid, as shown by its extraordinary expansibility. Only one other known liquid has anything like an equal rate of expansion, and that is nitrous oxide. The occurrence of this body in minerals is, it is said, highly improbable, and it seems, on the whole, that we may be justified in including liquid car-bonic acid among natural liquid mineral substances.

A few words which relate to the formation of the stones we have mentioned, must conclude our notice of this highly valuable paper. The facts

quoted show that ruby, sapphire, spinel, and emerald were formed at a moderately high temperature, at so great a pressure, that water could be present in the liquid state. The structure of the diamond does not afford positive evidence of a high temperature, while the absence of cavities containing water or saline solution, does not prove that water was entirely absent. At the same time, the presence of what appears to be liquid carbonic acid, seems to show that only a very little water could be present either as a liquid or as steam.

#### PARLIAMENTARY NOTES.

THE most important event in the House of Commons recorded by us last week, was the moving of the Navy Estimates by Mr. Childers. We now have to notice a circumstance of equal importance—the presentation of the Army Estitimates-which took place on the evening of yesterday week. The House having gone into committee upon the question, Mr. Cardwell proceeded to move the Estimates. From the remarks of the right hon, gentleman, it appears that the real net reduction in the cost for the coming financial year, as compared with the past, amounts to £1,196,650, or equivalent to a saving of more than 10 per cent. This result had been attained by means of a review of the distribution of the troops in the colonies, and the arrangement effected by the late Government, under which a greater control had been established over the expenditure in matters of supply. The forces at home provided for by the Estimates were 90,677 men, being an increase on the previous year of 3,172 men; but to this number was to be added a regiment recalled from New Zealand, and another from the Cape of Good Hope, which would bring up the total to 92,000 men, and with a view to economy and efficiency alike, the battalions had, following the example of other countries, been reduced to 560 men each. The force in the colonies now stood at 34,850 men, a diminution of 15,170 men; the principal reductions being in Canada and the North American possessions, where the number had been brought down from 16,185 last year, to 6,245 in the pro-sent. The other reductions had been effected at the Cape and New Zealand, and a West Indian regiment had been removed from Lagos, in consequence of the cessation of the slave trade on the West Coast of Africa. All these reductions had been made upon the principle that the true defence of the colonies was not to scatter detached troops over them, but to let the world see that war with them meant war with England. The colonies were thus encouraged to rely upon their own energy, whilst the strength of the empire was consolidated and rendered all powerful for their defence in case of necessity. The nature and results of the reductions were

next described in detail by the right hon, gentleman, who mentioned, as one important feature of the contemplated changes, that with 92.000 men, comprising sixty battalions in this country, and 96,000 in India and the colonies, a considerable advance would be made towards enabling the men to pass one half of their time at least on The object which the War service at home. The object which the War Office had proposed to itself was the solution of the problem how to maintain a moderate army in time of peace, and make it effective in time of war. Bearing this in mind, he laid down these propositions: that the army ought, as regarded both men and material, in time of peace, to be comparatively small; next, that its efficiency the highest attainable; third, that it should be should be in a form capable of easy expansion; and, last, as regarded its material, that it should be of the highest quality and the greatest efficiency, and should not be accumulated in proportions so large as to be liable to become obsolete.

With regard to the militia, the right hon. gentleman stated that there was no intention to alter its local character and connection with the counties, or to withdraw from the lord lieutenants any patronage they now enjoyed in the appointment of officers to the force. But it was proposed to establish a relation between the regular army and all the voluntary forces in such a manner that the country might feel that its whole strength was welded and consolidated together. The con-

ditions upon which the officers should be chosen would be such as to ensure a greater amount of military qualifications, and £20,000 was allocated in the Estimates for improving the position of the militia officers, and with the hope that the effect would be to remove the present disinclination of gentlemen to enter the militia. The maximum of gentlemen to enter the militia. the force of militia for England and Scotland would be 90,000 men. No regiment would be allowed to exceed 960 men, and he was now engaged with the Horse Guards in making arrangements for brigading militia and yeomanry regiments with regular army. As to the volunteers, it was intended that no locality should have a greater number of corps than it required, but a larger proportion would receive the grant. Officers and non-commissioned officers would be selected solely for their efficiency, and neither social position nor any other recommendation would be allowed to compensate for a want of perfect efficiency.

With regard to the volunteers, Mr. Cardwell observed that if Parliament were asked for an additional contribution, it must not be by sowing broadcast an addition to the capitation grant, but in some mode the direct consequence of which would be to contribute to increased efficiency.

The right hon, gentleman then proceeded to sum up the whole of our military force, his statement showing that there were 90,677 regulars at home, 83,000 militia, 13,700 yeomanry, 2,000 first army reserve, 21,870 second army pensioners, and 170,581 volunteers, making a total of 381,828. Mr. Cardwell observed that we ought not to become them with a smaller force than this, which was easily capable of being augmented to 400,000 men, especially as not one of the other great Powers of Europe had a force which fell below 1,000,000 of men.

Passing on to the subject of material, the right hon, gentleman entered at some length into a detailed statement with regard to artillery and small arms. In the Fraser gun and Snider ritle we had the best weapons at present known to science, although the Martini-Henry small arm would probably supersede the latter. He also explained the nature of the arrangements made between the War Office and the India Government, and the relations subsisting between, and the joint action of the War Office and the Hotse Guards. Finally, he moved that a land force of 127,366 men be maintained for the service of the year in Great Britain and Ireland.

A discussion of considerable length followed this statement, after which the vote was agreed to.

At the same sitting, Captain Dawson-Damer asked the Secretary of State for the Home Department, whether that structure called a semaphore (an illustrated description of which appeared in our issue for December 24 last), on the crossing near the Houses of Parliament, was conducive to the safety of the public; and, if not, whether he would give instructions for its removal.

Mr. Secretary BRUCE said, that before the commencement of every session an order was issued to the Commissioner of Police to devise measures for the safety of members proceeding to and from the House, and members of the police force were stationed, at great risk to themselves, at the crossing, to ensure the safety of hon. members. During the last session one poncenna injuries received while executing his duty, and Davisment were knocked down. During the last session one policeman died from The signal crected was intended to provide against those dangers, by giving notice to passing vehicles in a more effectual manner than could be done by the outstretched arms of a policeman. The experiment had been partially successful. The signal riment had been partially successful. The signal was obeyed by the drivers of omnibuses and cabs, and was beginning to be obeyed by the less intelli-gent drivers of other vehicles. It had already contributed so much to the safety and convenience of the public, that the Commissioner of Police was satisfied of its usefulness, and recommended that the system should be extended to other parts of the metropoils.

AMERICAN LOCOMOTIVES AND ROLLING STOCK.

BY MR. ZERAH COLBURN, M. INST. C.E.

AT a meeting of the Institution of Civil Engineers, held March 9, Mr. C. H. Gregory, President, in the chair, a paper on the above subject was read. Before commencing the ordinary business, the President referred to the recent decease of one of the oldest members, Mr. James Simpson, past President of the Institution of Civil Engineers. The President observed that Mr. Simpson had left a name which would long be

Digitized by GOOGLE

remembered with honour; by the world as a man of the most upright character, and a distinguished hydraulic engineer, by the Institution of Civil Engineers as one who for many years was a most regular and valued attendant as the meetings, and by those who enjoyed his intimacy as a faithful and devoted friend.

In the paper read it was remarked that in construction and working, the American railways represented little more than a modified application of English practice. When the systems of the railway machinery of the two countries were compared, many of the differences which first struck the eye were found to be external rather than fundamental, and so, too, many of the peculiarities of construction now retained in America were due to the initiative of English engineers.

Pursuing the history of introduction of locomotives into the States, it was observed that the first two worked in America were made in England, in 1828, one by Mr. George Stephenson, the other by Mr. J. U. Rastrick. In the same year, the engineers of the then contemplated Baltimore and Ohio Railroad visited this country. when Mr. Robert Stephenson suggested to them what was now the distinguishing feature of all American railway rolling stock, viz., the bogie, to be applied to the engines intended to work round curves of 6 chains radius, at that time proposed to be adopted. The bogie, which had grown out of William Chapman's invention of 1812, was then, Mr. Stephenson stated, in regular use upon the quays of Newcastle. Having regard to the character of the lines first constructed in the States, it was essential that the locomotives should be light and cheap, and the first engines made there, between 1830 and 1832, weighed only from 34 tons to 4 tons. Some of the Englishbuilt engines imported at about that time had their leading wheels removed, and a swivelling bogie substituted. The bogie was not, however, exclusively employed. Considerable numbers of engines made by Messrs. Stephenson and Co., Messrs. Bury, Curtis, and Kennedy, Messrs. George Forrester and Co., and Messrs. Braithwaite and Co., were afterwards imported and worked as originally constructed; and, as late as 1855, at least one hundred locomotives of English con-1855, at struction, or made almost exactly upon Messrs. Stephenson's plans, could have been counted at work in the States. For many years wood only was employed as fuel, and as it produced great quantities of sparks, as annoying to passengers as they were dangerous to goods, much ingenuity was directed to the problem of separating and withholding them from the escaping smoke and steam; and the voluminous "spark arresters" were very successful in this respect, while they gave also an individuality to the engines. Again, the rigours of the American winters compelled the adoption of some kind of shelter for the enginemen and firemen; and this was afforded by the bulky, and often extravagantly painted, "cabs," which imparted a novel appearance, but without in any way affecting the principles or economical con ditions of working of the engine.

As high speeds were seldom attempted upon the As mgn species were sentom attempted upon the early American lines, the greatest steam tractive power was sought and obtained, both by working high-pressure steam and by employing driving wheels of small diameter. Thus, although, in 1835, the English-built engines, and those copied from them were worked at 50th pressure and from them, were worked at 50lb. pressure, and had 5ft. driving wheels, it was not long before American practice settled upon 90lb. to 100lb. pressure and 4ft. or even 3ft. 8in. driving wheels. It was soon found, however, that the adhesion weight upon a single pair of wheels, necessary to work up this increased steam tractive force was too great for the strength of the way, and coupling was then resorted to; and now, with the exception of a few light tank engines on branch lines, there was not probably an engine in the States having single or uncoupled driving wheels. Four tons might be said to have been the maximum per wheel for many years, while three tons was the more usual average. Compensating levers, generally made of long steel springs, were now employed on all American engines, whereby the weight was not only equalized between the coupled wheels, but the effect of a jolt upon one was divided and distributed, through the springs and levers, upon the other pair. For some years, too, the bearings of the outer ends of the springs of the coupled wheels were made to rest upon india-rubber blocks.

The details were then given of several descriptions of engines long worked on the Baltimore and Ohio and Reading Railroads, as well as of that goods and passenger trains amounted on an average Horse Guards.

employed to work the incline of 1 in 161 and 114 mile long at the Madison terminus of the Madison and Indianapolis Railway. Compared with English practice, in which six-wheeled coupled engines had from 5 tons to 6 tons on a wheel, and eight-wheeled coupled engines had 7 tons on a wheel, it was observed that the subdivision of weight in American engines was carried about half as far again, or, in other words, that they averaged only about two-thirds as much weight per wheel, and that they thus required, for a given total weight, half as many more wheels. Except with smaller wheels, this could not be done on any practicable length of wheel base; but none of the American goods and bank engines, of which the particulars had been given, had wheels larger than 3ft. 11in. in diameter. There were objections also, of much weight, to coupling a large number of wheels from a single pair of cylinders. It was more or less difficult, if not impossible, to preserve an exact equality in the diameter of the wheels, an exact parallelism of the axles, and an exact equality in length of the coupling rods. extent to which coupling had been carried in American goods engines had been due, in a great measure, to the following expedients. coupled wheels were as equally loaded as possible; their tyres, in a majority of cases, were of chilled cast iron, since replaced by steel, and the former were cast, and the latter turned, nearly or quite to a cylindrical form, or with but little or no cone. The driving wheels were the middle pair, or in the case of an even number of pairs, one of the pairs nearest to the mid-length of the wheel base; compensating levers were employed, and adjusting wedges had for some years been applied to the axleboxes. The coupling rods, in many cases, were made without brasses, round steel bushings being fitted to circular eyes formed at the exact required distance apart in the ends of the rods.

With the exception of the leading and trailing wheels, the coupled wheels were generally fitted plain cylindrical tyres having no flanges. Outside coupling cranks, necessary with outside frames, had rarely been employed, and were never The coupling rods were counterweighted within the wheels themselves, no attempt being made, in inside cylinder engines, to set off their weight against that of the cranks and attached parts. In other words, the coupling pins of the driving wheels were coincident, on each side of the engine, with the position of the crank in inside cylinder engines, and, of course, necessarily so in outside cylinder engines. The experience of American locomotive engineers had been to the effect that with this arrangement, which was the opposite of English practice, the axle-boxes wore more uniformly, and that there was less "knocking" where a little play in the horn plates had once begun. And lastly, the length of the crank being one-half the radius of the small coupled wheels employed, any inequality in the length of the coupling rods was attended with less slipping and binding than where, with larger wheels, the crank was but one-third the radius of the wheel.

The general form of passenger engine now in uso in the States was then described. It had, in most cases, outside cylinders—indeed, inside cylinder engines had not been built for many years-and it had invariably four coupled driving wheels, and a four-wheeled bogic. The leading dimensions of the representative type of passenger engines were—cylinders from 15in. to 17in. in diameter, with a length of stroke of from 22in. to 24in., and coupled driving wheels of from 5ft. to 5ft. 8in. in diameter. Such engines would exert a tractive force of 31 tons to 4 tons in starting, for which their adhesive weight, assisted sometimes by sand, was sufficient; and thus they could get quickly away from stations even with trains of a gross weight of 200 tons or more. Economy of fuel had not been studied to the same extent in America as in English loco-motives. The blast pipes of the former were smaller, the draught more forced, the back pressure greater, and less expansion was attempted in the cylinders, the link motion being generally arranged to cut off at one-third stroke as a minimum, and at nine-tenths or more as a maximum. It was thus that boilers of moderate size were made to supply steam for work equal to 300 indicated horse power, or the exertion of upwards of two tons of draught upon a passenger train at a mean speed of twenty-five miles an hour; but there was nothing remarkable in the consumption of from 50lb. to 60lb, of coal per mile in such work. It was stated that on the Pennsylvania Central Railroad, a line 356 miles long, with gradients of 1 in 100

to about 70lb. per train mile, the goods mileage being three and a-half times the passenger mileage. The coal was of excellent steaming quality, and cost about 3½d. in currency, or 2½d. in coin, per train mile. At this rate, a difference in consumption of 24lb. of coal per mile would only cause a variation of a penny per mile in the cost of fuel and it had been argued that such a waste was better than the alternative of employing an engine four tons or five tons heavier, to work with a less rapid rate of combustion, a slower piston speed, and more expansively.

The goods engines were moderate in weight, had large cylinders and small wheels, and drew heavy trains at a fair speed with a consumption of coal often amounting to 100lb. or more per mile. On the Pennsylvania Central Railroad, the standard type of this class of engine had ten whoels, of which six, each 4ft. Gin. in diameter, were coupled. The whole weight of the engine was only 31½ tons, and of this but 23½ tons rested on the coupled wheels, available for adhesion. The cylinders were 18in. in diameter, with a length of stroke of 22in. With 60lb, mean effective pressure per square inch upon the pistons, these engines would exert a tractive force, less their own internal resistances, of rather more than 3½ tons, or about one-seventh their adhesion weight, although in starting a train, or in ascending a gradient, with 100lb. pressure on the pistons, the steam tractive force would be 6 tons, equal to more than one-fourth of the adhesion weight, the efficiency of which would then be assisted, when necessary, by sand. Details of the performances of some of these engines were next given. In one case, after allowing for gravity 8 glb. per ton, for a train, engine and tender included, of 1,040 tons weight, the total resistance would be four tons, and thus the work done on each mile was calculated to be equal to 24 horse power exerted for one hour, and if the estimates could be trusted, the conand if the estimates could be trusted, the consumption of coal per horse power per hour would not exceed from 4½b. to 5½b. The speed probably was not more than 15 miles an hour, corresponding to 360 horse power. The policy of American railway managers with respect to goods traffic, as it was also the policy of the managers of most of the French lines, was maximum loads at slow speeds, involving a minimum resistance per ton, and correspondingly minimum resistance per ton, and correspondingly a minimum working expenditure per ton.

No experiments upon the dynamical efficiency of American engines had been made, so far as the author was aware; but he had run an experi-mental train on the Erie Railway, over the whole length of the line and back, a total distance of nearly 900 miles. The same engine was employed throughout the run, occupying in all nearly weeks, making an average for each week-day of about 50 miles. The results of these experiments appeared to show that the resistance of bogie rolling stock, even under disadvantages, was less than that of English rolling stock as ascertained by the best authorities, and also that the ratio of adhesion to weight averaged considerably more in the States than in England. With respect to adhesion, as the surfaces in contact were identical with those on English railways, indeed the rails and tyres in general use in the States were commonly of English manufacture, and any difference in this respect must be attributed partly to the influences of climate and partly to a better application of sand, when necessary to increase the bite upon the rails. The sand was dropped equally upon both rails, not in intermittent handfuls down a pipe on one side of the engine only, but by means of the hand gear and re-gulating valve since adopted on the North London Railway. The experiments in question were, no doubt, influenced by the favourable circumstances of weather, and something was to be allowed also for the great length of train drawn, very long trains having a less tractive resistance per ton on a level than short ones, and something, possibly more than was commonly supposed, might have been due to the use of oil-tight axle-boxes, the saponaceous compound grease " being nowhere known as being nowhere in use on railways in the States. Messrs. Guebhard and Dieudonne's experiments, made in 1867, on the Eastern Railway of France. showed a considerable diminution in the resistance of oil-boxed rolling stock as compared with that fitted with greaseboxes.

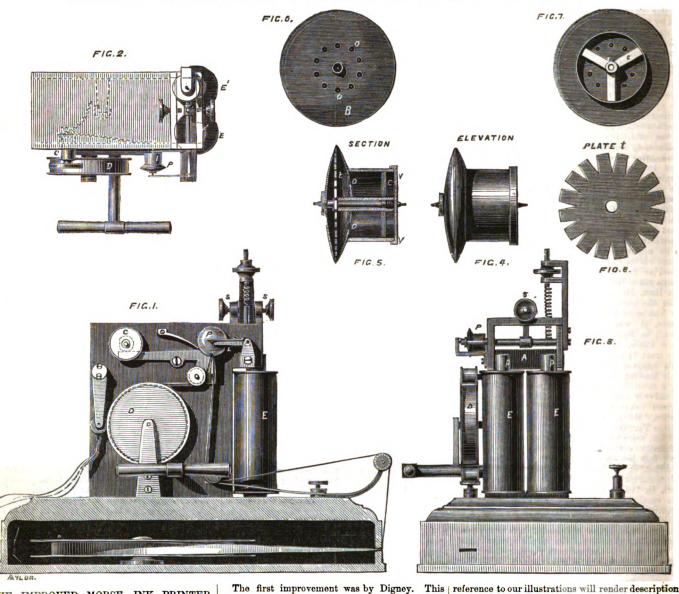

(To be concluded in our next.)

It is announced that Lord Strathnairn will succeed the late Lord Gough in the command of the Royal Horse Guards.

#### THE IMPROVED MORSE INK PRINTER.

PATENTED BY THE INDIA-RUBBER, GUTTA-PERCHA, AND TELEGRAPH WORKS COMPANY.

#### THE IMPROVED MORSE INK PRINTER.

THERE are few telegraph instruments that have come into more general and universal use than the special type known as Morse instru-ments. For many years, the only recording form adopted was that of "embossing." In America, Morse instruments were, and are, still greatly used, but generally as "founders," the messages being received purely by sound, and no record whatever kept. In England and Europe, the form of recording or "embossing" instruments was much the same. Whilst the various parts of the instrument frequently underwent changes, the embossing arrangement remained almost identical, and consisted of an electro-magnet and an armature, sisted of an electro-magnet and an armature, having attached to it a lever of varying length, having at its free end a metal style. On the attraction of the armature, this style, pressed against a strip of paper passing over it, and so "embossed" the Morse letters. This kind of record is not sufficiently permanent, the marks being accellent freed and when the whole of printing record is not sufficiently permanent, the marks being easily effaced, and when the plan of printing with ink was introduced, it met with a great deal of attention, and improvements have been going on up to the present. The first introduction of Morse printing by ink is due to a Hungarian of the name of Mr. Thomas Sohn, this was in about 1950. The thing was in about 1950. Mr. Thomas Sohn; this was in about 1856. In this plan, the paper travels in front of a small disc, half immersed in Indian ink; the disc being in connection with the armature, is forced against the paper when any signal is made, and the marks are shown accordingly. There was great room for improve-ment in this machine, and improvements followed fast on improvements, but the system remained the same. The marks were made on the paper by the action of the armature. In some cases, the armature lifts the paper against the printing disc; in others, the disc is moved against the paper.

consisted in having a felt roller provided with ink; against this revolved a thin disc, whose outer edge was consequently well provided with ink. Beneath this disc passed the paper, supported on a lever, in connection with the armature. The signals were recorded by the pressure of the paper against the disc. This instrument has been very generally adopted, as also have those containing the improvements of Messrs. Siemens. The first of these is a slight variation upon that of Digney, substituting for the felt roller (which frequently requires replenishing) a small bottle containing a supply of the ink; the end of this bottle is stoppered with thick felt. By fixing this in place of the felt roller, with mouth downwards, a constant reservoir is formed for the disc to revolve against. It has this great disadvantage. With heat, &c., the felt is apt to dry and harden, and the supply of ink becomes too small. Clerks are apt to encourage the supply by perforating the felt with pins and needles, the result being an overabundant supply, deluging the instrument with ink. In their second improvement, Messrs. Siemens enclose the ink in a bottle or bath, in which the disc is half immersed. The other modifications are not sufficiently good to invite further attention. In all the plans we have called attention to, there is a disadvantage that is embraced by all—a fault that with the mechanism employed in telegraphy should invariably be absent—the quantity of ink and dirt that is sure to get about the instrument, and, with the exception of the last improvement, and uncertainty of supply.

The latest improvement that has been made in the Morse ink printing instrument is that patented by the India-rubber, Gutta-percha, and Telegraph Works Company (Limited). In addition to the absence of the disadvantages specified, it possesses several peculiar and valuable advantages. A

reference to our illustrations will render description more easy. Figs. 1, 2, and 3 show views of the printing instrument itself, and figs. 4 to 8 explain the construction of the "ink pen." The electromagnets E E attract the armature A (figs. 2 and 3). Attached to the armature is an arm L, having at its free extremity the pen P, under which passes the printing paper, proceeding from the roll under the instrument. The paper is drawn off by the drum D. The action of printing is the same as in other instruments. The electromagnets being excited, the armature is attracted, and the pen comes against the paper, and causes a mark or line so long as the current is continued, or causes the usual Morse signs to be recorded at the volition of the sender. It is in the construction of this pen that this improvement differs most materially from other inventions, and claims to be an improvement per se. It is not only a pen, but a reservoir—a continual wasteless pen, requiring refilling but seldom, always ready and never failing, and clean in the extreme. Fig. 4 gives an elevation of the "pen," and fig. 5 a section. The ink is contained in the reservoir R, and is filled by unscrewing the back portion b b. The ink is poured into the reservoir through the holes at C (fig. 7). In front of the reservoir is a concave plate B, forming one of the nibs of the pen, and having holes at o o (fig. 6), through which the ink passes into the pen. The other nib of this pen is formed of a piece of metal similar to B, but without perforations. Mounted on the same axis, and between the two nibs (fig. 5) is placed the slotted disc X (fig. 8), which serves to carry the ink to the nibs. It will readily be seen how clean and certain this pen is in its action—how neverfailing, so long as any ink is left—and without waste, as no ink can be used, nor can any come from the pen unless the paper touches it.

The other improvements in this instrument, which is a direct-acting printer, are, first, the addition of the large drum for drawing off the paper. This drum presents a greater surface, thus lessening the power of spring on the biting roller, in consequence of which two wheels and pinions in the train can be dispensed with. By the arrangement of the cam at O, the paper is moved to or from the "pen," as the machine is started or stopped, thus keeping it free, should the instrument be required for an intermediate station, and preventing the waste of ink which would otherwise be the case; by insulating the brackets and which is a direct-acting printer, are, first, the addiwise be the case; by insulating the brackets and wise be the case; by insulating the brackets and screws S at the top of the frame, the printing bar or armature may be used for transmitting, as in ordinary instruments. By the power and delicacy of the electro-magnets, it is possible to work this instrument on long circuits without relays.

The second improvements in this instrument and

Instrument on long circuits without relays.

The several improvements in this instrument, and the excellent manner in which it is constructed, would in themselves be sufficient to recommend it to attention, but the special feature it possesses in its "ink pen," with its numerous advantages, places this instrument in the first rank as a Morse pristing machine. We speak advisedly with record. places this instrument in the first rank as a Morse printing machine. We speak advisedly with regard to its advantages and utility, as we have witnessed its working at the United Kingdom Telegraph Company's office, where it has been working for several months past without relay on the long circuit of London and Glasgow. During that time it has earned a large amount of praise, and the extraordinary clean state of the instrument, as compared to the other ink printers, was remarkable. compared to the other ink printers, was remarkable.
An instrument of similar construction, but with the latest improvements, was exhibited at the late soirée of the Royal Society by the patentees.

### THE FOUNDER OF THE SCIENCE OF THERMODYNAMICS.

one of the meetings of the Manchester AT one of the meetings of the Manchester Literary and Philosophical Society, Professor William Jack, M.A., laid on the table Professor Tait's new work on Thermodynamics, presented to the Society (of which he is an honorary member) by the author. In so doing, he called attention to the estimation in which Professor Tait held the work of Dr. Joule in laying the foundation. held the work of Dr. Joule in laying the founda-tions of the science. It was well known that the claims of Mayer to the first place in connection claims of Mayer to the first place in with the subject were strenuously advocated by with the subject were strenuously advocated by some authors. Professor Tait considered those of some authors, appearably superior. The equiva-Dr. Joule incomparably superior. The equiva-lence of a definite quantity of work to a definite quantity of heat had been indicated as extremely probable by the experiments of Rumford; and Davy's celebrated experiment, in which he melted ice by friction, confirmed the view that work was really so convertible, modifications of Rumford's experiments would have enabled him to present the heated body in nearly the same state after as before heating, except as regarded the increment of temperature. These, however, had not been made, and the experiments appear to have been

In all heating there are three mechanical results neglected. In all heating there are three mechanical results of work possible:—I. That the particles of the body may be set into more rapid vibration.

2. That their distances may be changed by dilatation or contraction, work being used up in accomplishing this change, just as when weights are raised against gravity, i.e., when their distance from the centre of the earth is altered. 3. That any outside forces acting on the body—a.e. present from the centre of the earth is altered. 3. That any outside forces acting on the body—e.g., pressures in the case of a gas—might have their points of application altered. The two first are linternal effects—the last external. Mayer and Joule both of them applied the principle of the transference of heat into work to air compressed by work. With this substance Joule showed perimentally that the first two effects might be disregarded altogether in comparison with the third. Mayer assumed this without any proof, assumption. The argument of Mayer was therefore only an ingenious speculation—Joule's therefore only an ingenious speculation-

Joule, however, went much farther than Mayer.

"In all the action, and Professor Tait saysaction, and Professor last says—in all the scientifically legitimate steps which the early history of the principle records, Joule had the priority. The reader should clearly recognize the priority. The reader should clearly recognize the fact that the experimental foundation of the principle in its generality, and the earliest suggestions of many of its most important applications, belong unquestionably to Joule. Trained to account a experiment and profound testigation in the accurate experiment and profound reflection in the school of Dalton, the pupil has not only immortalized himself, but has added to the fame of the

On the other hand, it appears to Professor Tait just to quote a passage in which Helmholtz, no doubt in view of Mayer's later work as well as doubt in view of Mayers later work as wen as that at the time of the foundation of the science of mechanical effect, thus expresses himself. Mayer was not in a position to make experiments; he was not in a position to make experiments; he was repulsed by the physicists with whom he was acquainted (several years later I was similarly treated), and could scarcely procure room for the publication of his first compressed exposition. You must know that in consequence of these repulses his mind at last became affected. It is difficult now to transport oneself back into the circle of thought of that time and to perceive clearly how absolutely new the matter then circle of thought of that time and to perceive clearly how absolutely new the matter then appeared (25 years ago). It seems to me that even Joule had to struggle long for the recognition even Joule had to struggle long for the recognition of his discovery. Thus although no one will deny that Joule has done far more than Mayer, and that in the early writings of the later many points are not clear, I believe that Mayer must be considered as a man who independently and for himself discovered this thought which has produced the grandest recent advance of natural science, and his deserts are by no means diminished by the fact that simultaneously another, in another country and sphere of action, made the in another country and sphere of action, made the same discovery, and indeed has since developed it

better than he."
Mayer has many titles to the gratitude of scientific men, and one of the chief of them will scientific men, and one of the chief of them will doubt always be his anticipation of the true doctrine of the equivalence of heat and work. Octrine of the equivalence of heat and work. But as it was founded on an experiment which was only sound by chance, in interpreting which he had not seen that his conclusion depended on ne nad not seen that his conclusion depended on one precise answer to a question that had not suggested itself to his mind, it was anticipation and not discovery. Dr. Joule remains the true founder of the modern science of Heat.

## RECENT LAUNCHES.

RECENT LAUNCHES.

I AST Saturday afternoon, the "Active" was successfully launched from the Thames Iron Works. This vessel is a sister ship to the "Volage" which was launched from the same yard a fortnight previously. She is from the designs of Mr. E. J. Reed, C.B., the Chief Constructor of the navy, and is specially designed to keep the sea for a long period. The "Active" is 270ft. in length between perpendiculars, 247ft. length of keel for tonnage, 42ft. breadth extreme, 41ft. moulded breadth, and 15ft. 2in. depth of hold. Her burthen in tons, O.M., is 2,321 59-94, and she will have engines of 600 nominal horse power. With this great power to her tonnage, her minimum full-power speed is expected to be 15 knots. Her armament will be six 6½-ton rifled guns, and two 64-pounders. Messrs. Humphrys, Tennant, and Co., on the same day the serve corrects a Druid".

full-power speed is expected to be 15 knots. Her armament will be six 6½-ton rifled guns, and two 64-pounders. Messrs. Humphrys, Tennant, and Co., are to supply the engines.

On the same day, the screw corvette "Druid" was launched at Deptford Dockyard, in presence of the Princess Louise and Prince Arthur. The Princess Louise christened the vessel in the usual style, and the ship moved down into the water amid the hearty cheers of a large number of spectators. Their Royal Highnesses and the principal visitors drank success to the "Druid," and with this the last of the launches at Deptford was brought to a close. The "Druid" was designed by Mr. Reed. She will be furnished with engines of about 350-horse power. Her burden in tons is 1,322 24-94ths. Her principal dimensions are, length between perpendiculars, 220ft. 0½in., length of keel for tonnage. 194ft., breadth extreme, 36ft.,

each, and they remained sound, except the Palliser, which was cracked in the tube near the muzzle There the experiments ceased for a time, but they are now in progress again. The guns are all of 9in. calibre. The Fraser gun, with thin steel tube, has lately been fired another 500 rounds with battering charges, and remains perfectly serviceable. The First 400 rounds with 30lb. charges, the vent being at the rear of the charge; then 200 rounds with battering charges of 43lb. At this stage the gun was wanted for experiments at Shoeburyness, and was re-vented for the purpose. There it was fired the times with 43lb. charges. Before continuing the test it was decided to do so with the vent in the service position. The gun was accordingly turned round and vented in its previous lower side. It has just completed its third series—500 rounds, this time all with 43lb. battering charges. From the commencement the projectiles have always weighed 250lb., the service weight. The gun has, therefore, fired up to this time 400 rounds with 30lb. charges and 250 projectiles, and 714 rounds with full battering charges of 43lb. English large-grain cannon powder. This makes about 19 tons of powder and 124½ tons of shot. The steel tube is condition for firing. We know of no gun, either the seat of the shot, but remains in excellent worn at the seat of the shot, but remains in excellent to the seat of the shot, but remains in excellent upon to stand such an extraordinary trial on real so severe a test. Indeed, it may be said that no service—certainly not in one war. An Armstrong gun of the Elswick pattern has fired a larger number of rounds, but not so many with battering charges of powder. We shall watch with much interest the further trials of these four guns—the representatives of powder. We shall watch with much interest the further trials of these four guns—the representatives of English designs and manufacturing skill.—

# OUTRIDGE'S EQUILIBRIUM SLIDE VALVE.

OUTRIDGE'S EQUILIBRIUM SLIDE VALVE.

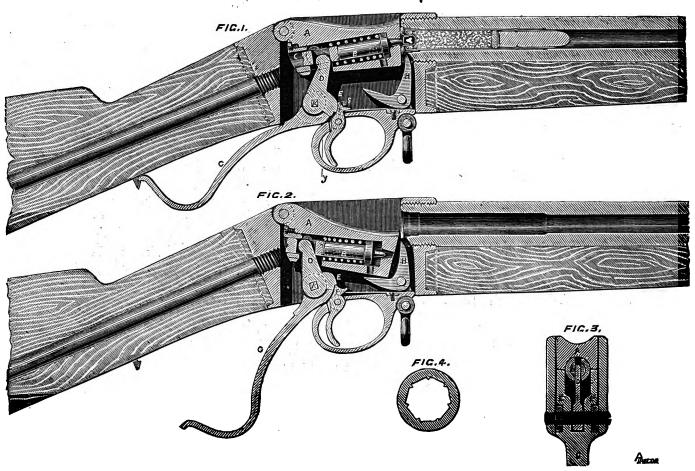

THE trial of the engine on the Isle of Wight (Ryde and Ventnor) Railway, to which Outridge's equilibrium slide valve, described and illustrated in our impression of Friday last, was fitted, took place on Saturday last. We have much pleasure in stating that the engine started without any hitch. The valve spindle was then uncoupled and the valve worked by hand, the regulator being full open, and the pressure in the boiler 100lb. This experiment proved that it worked with perfect ease. The engine was then run to Ventnor and back (26 miles), with a light load, and it also did some heavy shunting, on an incline of 1 in 78. Throughout the trial the valves were perfectly tight, and worked with entire satisfaction. At a future date we intend to give another report, future date we intend to give another report, showing the effect of the valve on the load which snowing the effect of the valve on the load which the engine will pull, and also what effect it has on the consumption of fuel. We congratulate Mr. Outridge upon having effected so efficient an im-provement in the slide valve, and the Isle of Wight Railway Company upon having adopted it.

One of the most interesting natural curiosities in Cornwall, "the Tolmen," or, as it is sometimes called, "the Main Rock," has just been destroyed. It was situate about midway between Penryn and Helston, to the south of the highroad, and weighed about 800 tons. It was 33ft. long, 14ft. high, and 19ft. in breadth, and was of an oval shape. It was placed in a most extraordinary position, and from this fact, as well as its immense size, was an object of much interest to tourists as well as to the geologist. The Tolmen rested on the point of two detached rocks, and underneath it was a free passage. Immediately beneath "the Tolmen" was a valuable granite quarry, which has been worked to the depth of 40ft. close up to the bed where the Main Rock, rested. This has been rented by some one, who, unknown to the proprietor, Mr. Hosken, had a hole bored underneath the rock and charged, and this, when fired, threw the Tolmen off its bed, and caused it to roll into the quarry, 40ft. below. ONE of the most interesting natural curiosities in

when hered, threw the Tolmen off its bed, and caused it to roll into the quarry, 40ft. below.

The Manufacture of Watches and Clocks,—A most interesting and instructive little work, describing briefly, but with great clearness, the rise and progress of watch and clock making, has just been published by Mr. J. W. Benson, of 25, Old Bond-street, 99, Westbourne-grove, and the City Steam Factory, 58 and 60, Ludgate-hill. The book, which is profusely illustrated, gives a full description of the various kinds of watches and clocks, without visiting the above establishments or consulting this truly valuable work. By its aid persons residing in any part of the United Kingdom, India, or the Colonies, are enabled to select for themselves the watch best adapted for their use, and have it sent to them with perfect safety. Mr. Benson, who holds the appointment to the Prince of Wales, sends this pamphlet to any address on receipt of two postages stamps, and we cannot too strongly recommend it to the notice of the intending purchaser.— Advr.

#### MARTINI-HENRY RIFLE.

#### THE MARTINI-HENRY RIFLE.

NHE question of the military arm of the future. which has so frequently been discussed in our columns, appears at last to be definitively settled by the adoption of a rifle bearing the above name. This weapon is the joint production of two inventors—Mr. Martini and Mr. Henry—the breech mechanism of the former and the rifling of the latter having been adopted by the Govern-ment. The progressive steps which have led to the final selection of this arm have been placed so fully before our readers as they were developed, that it is needless here to do more than briefly refer to the circumstance of the competition—the selection of nine breech-loaders from more than a selection of nine oreeon-loaders from more than a hundred which competed, and the apparently final adoption of the arm under notice. We say "apparently," inasmuch as the arm has yet to be tosted in practical use by the troops, a limited number of which will be first supplied with the new rifle. But we have no reason to apprehend that this trial will not lead to its final and general adoption in our army; indeed, judging from the severe tests it has undergone at the hands of the Small Arms Committee, we should say there was no chance of failure on any point.

The breech mechanism, as adopted, we illustrate

in our engraving, figs. 1 and 2, from which it will be seen that it is extremely simple in construction. Fig. 1 shows the breech, closed with the striker forward, and fig. 2 the breech, open ready for loading. The breech block A works on a pin, and contains the striker B, surrounded with its main contains the striker B, surrounded with its main spring. This striker is confined in its chamber by the hollow screw C. The bottom of the breech block is slotted, to allow the end of the tumbler D to engage with the striker. The tumbler is mounted on the axis K, which is squared at the point of contact with the tumbler, so that as the tumbler is raised or depressed the axis moves with it and so alters the position of an indicator outside the look. The hand lever G in its downward it and so alters the position of an indicator outside the lock The hand lever G, in its downward movement, serves to open the breech, and draw back the striker. The tumbler moving with the fiver engages itself on the nose F of the trigger. A further continued downward movement of the lever G acts against the inner face of the hollow screw C, and causes the breech block A to lower itself on its pin as a centre. The upper part of the lever G is forked, and embraces the tumbler as shown

at E E, fig. 3. As the lever is pressed! down, the breech block is opened, and, as it moves, the tumbler is forced back, drawing back the striker, and compressing the main spring at the same time, till the nose F of the trigger engages with the tumbler rest. The object of the tumbler rest is to relieve the trigger from the whole weight of the tumbler and main spring. As the trigger is pressed, its first movement relieves the tumbler from its rest. The whole weight of the spring is now on the trigger, and a further pressure releases it. The working of the extractor is easily understood from a glance at the engraving; but at the same time it will be well to remark that the lower arm of the extractor H is so shaped that the first impact of the breech block with it serves to lossen the cartridge case in

block with it serves to lossen the cartridge case in the chamber; then, as it further descends, the motion of the extractor is more rapid, and the case is ejected clear of the gun. Fig. 3 is a transverse section of the breech block mechanism through the plane x y, fig. 1.

In the early patterns of the Martini system an indicating pin was provided at the back of the breech block and in the upper part of the stock, which projected when the arm was cocked. This indicator was worked by the head of the striker, and as it was found to get out of order, another and more simple indicator was substituted. As mentioned above, this last improvement is fixed on mentioned above, this last improvement is fixed on the end of the tumbler axis, and therefore shows exactly the position of the tumbler. In order to obviate any danger that might arise through carrying the arm loaded and cocked, the committee added a safety bolt S, which engages with

mittee added a safety bolt S, which engages with the trigger, and prevents it being moved. Other minor improvements have been made, such as lightening the cleaning rod, and modifying the shape and position of the sight.

The cartridge for this rifle is the invention of Mr. Henry, and, as it will be contained in a central-fire Boxer case, it is called the Boxer-Henry cartridge. It is 450 gauge, the bullet weighing 480 grains, and is composed of lead hardened with tin. A paper wrapper is placed round the bullet, the edges being returned into a slight cavity at its base. Pure beeswax is used for lubrication, and is placed between three diese made from jute cardboard. The charge consists of eighty-five grains of powder. This cartridge is shown in section in the barrel of the rifle at fig. 1

Turning from the breech mechanism and the

Turning from the breech mechanism and the

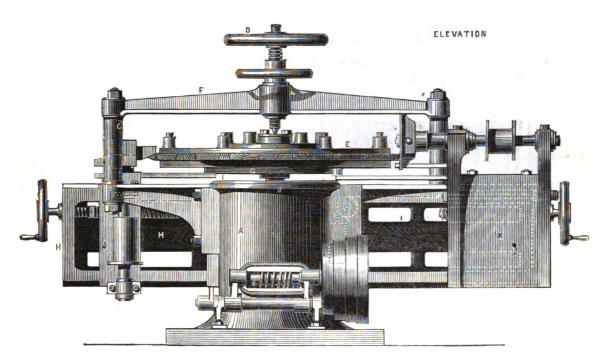

cartridge to the barrel of the new arm, we may observe that it is 35in, in length, and is rifled upon Mr. Henry's principle, shown in section in fig. 4. This is known as the polygonal system, and is seven-sided. Down each angle formed by the intersection of the planes of the polygon is araised rib, which is tangential to the same imaginary circle as that to which the plane sides of the bore are tangential. This form of rifling leaves the bore more cylindrical than any other, except perhaps the Armstrong many-grooved system. In it what Mr. Henry terms a re-entering angle is formed, thus affording to the bullet a bearing at fourteen points instead of seven. The pitch of the rifling is one turn in 22in., the calibre being 450 of an inch. The Henry barrel has proved itself singularly free from fouling, and the excellency of the rifling has fully maintained itself to the last. A rifle on this principle was fired 3,000 times without its accuracy being in the least degree impaired. With the cartridge above described, the Woolwich practice in the latest trials has habiintersection of the planes of the polygon is a raised without its steeling in the least degree managed. With the cartridge above described, the Woolwich practice in the latest trials has habitually given the unparalleled result of lodging the bullets in a square of about 2 ft. at a range of 1,200 yards.

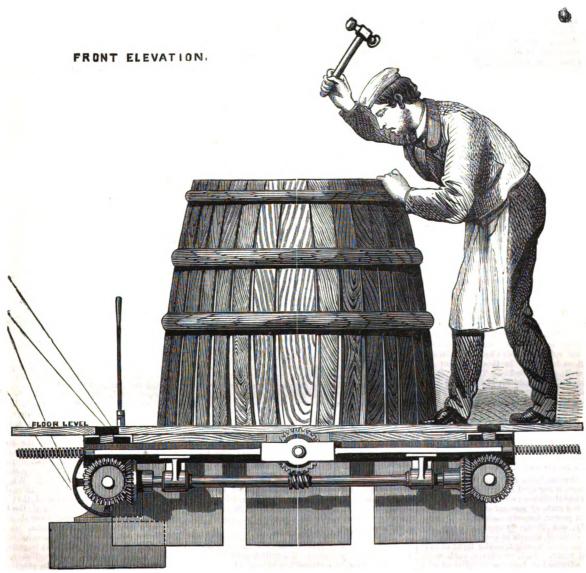

#### CASK-MAKING MACHINERY.

THE accompanying illustrations explain some very simple and effective machinery for trussing and heading casks, which has been lately patented by Messrs. M'Dowall and Sons, of Johnstone, near Glasgow. A pair of these machines have been put to work at a large steam cooperage in Whitechapel, where we saw them in action, and were able to judge of the facilities they afford in that trade. The trussing machine consists of a square, flat cast-iron table, over which move horizontally four curved jaws (changeable to suit the sizes of the casks to be hooped). These jaws are actuated, as is seen in the engraving, by screws passing through bearings at the centre of each side of the square platform. These screws have a very slow and simultaneous forward motion imparted to them by worm gear, and as they cause the jaws to advance they close the staves gradually till they are narrow enough for the trusses to be placed on them. Before this can be effected, however, the cask must be turned, and, therefore, THE accompanying illustrations explain some vever, the cask must be turned, and, therefor a temporary iron hoop, which opens with a kind of

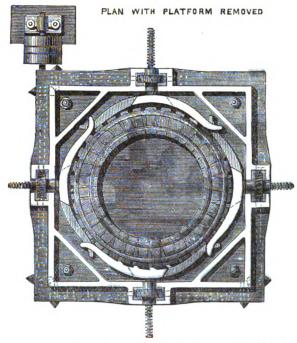

### CASK-MAKING MACHINERY.

BY MESSRS. McDOWALL AND SON.

#### CASK-MAKING MACHINERY.

ratchet clasp, is placed round the cask till the truss which passes over this hoop is driven down. The main peculiarity in this machine consists in the fact that the operation is carried on on a clear open platform, so that the workman can get all round the cask to hammer out and adjust the staves as they close in, securing an even arrangement of them, which was impossible, or only left to chance machines. The "heading," or caskhead turning machine, is of a type long in use, though, in this instance, beautifully designed and finished, and having in two particulars special improvements. The first of these consists in the use of spring studs passing through the upper table E, which, when clamped down on the boards to be shaped for a cask-head, press on and hold each board, even if their thicknesses are unequal. By this means, loose boards roughly sawn out can be placed in the machine without being dowelled, as was heretofore necessary, previous to rounding and "canting." The second peculiarity possessed by this machine consists in the method adopted of oval or "full" canting, so as to allow for the greater contraction of the wood across the grain than lengthwise. This is effected by means of a cam-wheel lying under the revolving table G on which the work is fixed, from which a slight horizontal motion is given to the head-stocks carrying the saw at one side, and the cannelling tool at the other. As the eccentricity required is very slight, the motion imparted to these tools does not affect the working of the straps.

#### THE SEA TORPEDO.

THE SEA TORPEDO.

We have received the following copy of letter on the subject of sea torpedoes, and a request for its insertion in our columns, from Captain J. Harvey, R.N., with whose invention in this direction our readers are well acquainted:—"To the Right Honourable Hugh C. E. Childers, M.P., First Lord of the Admiralty. 5, Keynsham Parade, Cheltenham, March 6th, 1869. Six,—As the Navy Estimates and our Navy Policy are about to be debated in the House of Commons, i venture to request your attention to a mode of naval warfare, which will be that of future combat upon the ocean; I am urged to so do, under a belief, which is shared by others who have studied with me the subject, that it is one of great importance to so maritime a state as England.

"I allude to the employment of the Sea Torpedo.

"I allude to the employment of the Sea Torpedo "I allude to the employment of the Sea Torpedo. Many years since, it engaged my attention, as it did also some other naval officers; seeing, as we did, that, in the then altered state of navigation by the introduction of steam power, torpedoes admitted of being easily, certainly, and effectively applied to the disabling or destruction of vessels at sea; and this, too, under any condition of weather, in the light of day, or darkness of night. And, moreover, such work of destruction admitted of being accomplished at a trifling cost, and with impunity also, by fast and handy vessels of comparatively small size, of light equipments, and inexpensive requirements; vessels that can keep long at sea, by reason of great available stowage for coal; having, too, the essential qualities of being excellent sea boats, and of speed under canvas. Such vessels could choose their time

under canvas. Such vessels could choose their time and opportunity of attack, which, as a rule, would be under cover of darkness of the night.

"By the late American conflict we were brought to a knowledge of the destructive capabilities of torpedoes. In that conflict of the war vessels disabled, or destroyed, about three-fourths were so disposed of by torpedoes: cannon were comparatively incorative.

disposed of by torpedoes: cannon were comparatively inoperative.

"Though the torpedoes were used disadvantageously, that is to say, passively, they nevertheless did, in most cases, the work of destruction effectively. But in future wars, they will be used actively or offensively; they will be brought into contact with the vessel attacked, and when in contact they will, by self-action, explode. Such mode of application will doubtless be that which will be generally practised in the present state of perfection enerally practised in the present state of perfection

of the arm.
"Looking into the history of torpedoes, it is some "Looking into the history of torpedoes, it is some-what extraordinary, indeed incomprehensible to those who are acquainted with their capabilities, that our naval authorities should apparently be so oblivious as to the occurrences in the late American war; and that they should continue to build monster war ressels, at an enormous cost, when, guided, as they should be, by established facts, as to their ability or inability to endure violent shocks of properly and suitably charged torpedoes. War vessels that we now have, and others in course of construction, will prove, there is reason to believe, worse than useless against vessels armed with sea torpedoes; for they would in all probability attend the sinking or destruction of such monster vessels at sea, where it would be hardly possible to save their crews.

"The Americans had not a knowledge of the sea

to their being published; so to lead to its thorough

to their being published; so to lead to its thorough investigation, which, I am constrained to say, has been hitherto withheld by the Government authorities.—I have the honour to be, Sir,

"Your most obedient Servant,

"John Harver, Captain, R.N.
"The Right Honourable Hugh C. E. Childers,
M.P., &c., Admiralty."

# THE NATIONAL BOILER INSURANCE COMPANY.

THE NATIONAL BOILER INSURANCE COMPANY.

WE have received the annual report of Mr. Henry Hiller, Chief Engineer to the National Boiler Insurance Company, whose head quarters are in Manchester. In this document are the following notes on the construction and management of boilers, which will interest many of our readers and may prove of practical value to some:—My Report for 1867 contained some general remarks on the construction of boilers. I now propose to refer to a few matters suggested in the course of our inspections bearing on the same subject and to others relating to the management of boilers. Many new boilers proposed for insurance are found of most inferior description, owing to mistaken notions of economy on the part of the purchasers, or to ignorance of the makers. Bad material, bad workmanship, bad form, insufficient staying;—some, or all of these, render many boilers quite unfit for the work proposed. The cylindrical egg-ended externally-fired boiler is still used extensively, although less safe, and requiring much more fuel than the internally-fired two-flued Boiler. The cheapness of fuel at collieries, and the simple form of this boiler, have caused it to be preferred at such works; whilst the objection to other classes has arisen, in many cases, through the ignorance of those entrusted with their construction, setting, or fitting up; or through subsequent gross mismanagement.

In some instances where plates have been renewed,

agement.
In some instances where plates have been renewed, In some instances where plates have been renewed, the holes were found to have been carelessly punched, and the "drift" so forcibly used that the old seams were partially or wholly fractured before the boiler was re-started; whilst the distorted holes were filled with huge, irregularly-siaped rivets. The danger of such practices is too evident of require comment. I would strongly advise that not only new work, but all repairs, should be executed by none but really good workmen; and with externally-fired boilers especially, the old seams of rivets should be cut off and new holes drilled. This course not only insures sound work, but also shews whether the old plates are good, or brittle and unreliable. If the holes in the two plates do not correspond, they should be carefully "rimered out," and suitable rivets inserted. "Drifting" should be studiously avoided, and if the seams are carefully laid, but little caulking will be requisite. With new boilers, or where extensive repairs have been executed, it is advisable to carefully and the hydraylic test, so that lankages if be requisite. With new boilers, or where extensive repairs have been executed, it is advisable to carefully apply the hydraulic test, so that leakages, if they exist, may be made good before the boiler is they exist, bricked in.

bricked in.

The advantage of riveted-joint beds for fittings and at manholes has been frequently urged in my reports. The insurance of a boiler was recently declined, the plates of which were only 5-16in. thick; whilst the unstrengthened manhole was no less than 18in. in width. The ends of some Boilers are so rigidly secured as to lead to serious fractures, whilst just here the straying is as slight that the are so rigidly secured as to lead to serious fractures, whilst in others the staying is so slight that the ends bulge outwards, and in many cases fail with disastrous results. Gusset plate stays riveted to stout angle iron are an efficient stay; but where longitudinal stays are preferred, they should be of large diameter, and secured by stout puts on each side of end pates, instead of by slight cottars or pins passing through angle iron. The risk of explosion of externally-fired boilers would be much reduced if they were strengthened by stout longitudinal stays.

destruction of such monster vessels at sea, where it would be hardly possible to save their crews.

"The Americans had not a knowledge of the scattorpedo in its present state, as to form and offensive application. They used torpedoes, with few exceptions, passively; that is, they were stationed in such positions which afforded the best chance of hostile vessels coming within their sphere of action: such applications of them is very costly and uncertain; also, unless placed in close proximity, requiring large numbers; and if fired by electricity, necessitating complicated and expensive arrungements.

"If a war should arise between maritime States, the sea torpedo will most assuredly perform a prominent part in the conflict. And if England should be involved in the calamity, those to whom her defences are intrusted will have to deal with the sea torpedo, since their pleasure, in the employment of such arm, will not be consulted by the war authorities of other States. Hence the policy of being prepared with vessels adapted to the service of the arm in question, and the necessity of officers being thoroughly well instructed in its every detail, and practised in its application.

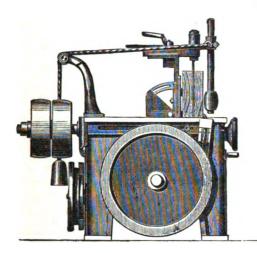

"As this is a matter which not only concerns you, as the Chief of our Naval Administration, but one also that greatly concerns the British public, involving, as it does, the protection of our shores, and more especially the protection of our shores, and more especially the protection of our shores, and more especially the protection of our commerce, laws therefore, in this letter, expressed freely, and I trust respectfully, my opinions upon it, with a view plesion of externally-fired botters would be much reduced if they were strengthened by stout longitudinal stays.

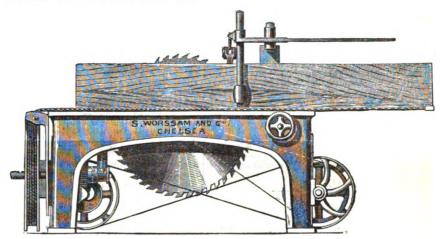

Several instances have been reported where boilers were seriously injured by overheating, through the external flues being carried above the low-water level. All flues should be so arranged that the plates may be quite covered by water; and in every case, even with small boilers, they should be made large enough to permit a man to pass along for inspection, &c. This can be arranged without affecting the efficiency of the boiler. Some boilers are so set, that a large portion of the lower part of the shell is buried in brick work; and plates so hidden sometimes become dangerously thinned before the corrosion is detected. Where it is not desired to use the side or other external flues, they should be so built and arranged that they may be entered for thorough inspection of the boiler. The seatings, &c., should never exceed 4½in. breadth where in contact with the plates, so that defects may not be hidden. The defects to which fittings are liable are briefly illustrated in preceding pages. Those of the very best construction and materials are not only most reliable, but in practice really the cheapest.

The safe and economical working of boilers de

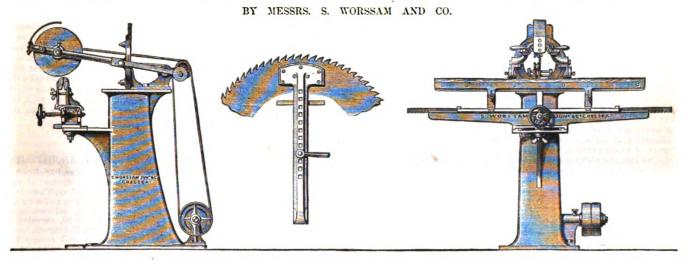

#### IMPROVED SELF-ACTING SAW BENCH.

BY MESSRS. S. WORSSAM AND CO.

#### SAW SHARPENING MACHINE AND CIRCULAR SAW-VICE.

managed by those in charge, that a few notes thereon will be of service. The advantages of regularity and steadiness in the working of all boilers cannot be over-estimated. Economy of fuel and increased production of steam always result therefrom, whilst the liability to defects of any kind is materially reduced. The fires should never be allowed to burn low, but the rate of combustion should be regulated by the damper. The dangerous practice of throwing open the fire doors to reduce the pressure should never be resorted to, as it is not only attended with great waste of heat, but positive danger, especially with externally-fired boilers, owing to the sudden cooling and contraction of the highly-heated plates. Uniformity of water-level and of steam pressure are indispensible. Thick fires are more economical than thin ones; the fuel on the bars may be from 8in. to 12 in. thick, according to the size of the furnaces; and by adopting the "coking" system of firing. i.e., pushing the fire towards the back end of the furnace, and throwing on the fresh fuel at the front, smoke may generally be easily prevented by the due admission of air through suitable perforations in the furnace door.

Where boilers are over-worked, or the fuel used

generally be easily prevented by the due admission of air through suitable perforations in the furnace door.

Where boilers are over-worked, or the fuel used is of such quality that the coking system of firing may be inapplicable, they may be fired in the ordinary way, the fuel being spread evenly over the whole grate surface. In such cases the admission of air at the door may be found insufficient to altogether prevent smoke, and necessitate the insertion of a perforated plate under the bridge; a second bridge being built a short distance behind the ordinary one, with an inverted brick bridge between the two. This plan I have recommended with good results. I may here note that fire-grates are often unnecessarily long; comparatively short grates are generally preferable and more economical. Heating the feed water by means of "Economisers," &c., is advantageous, as the temperature of the water in the boiler is thus more equalised, and liability to unequal straining of the seams, &c., reduced. Where water is heated by exhaust steam from the engine, this steam should not mix there-

with, as the grease from the cylinder often combines to form a deposit inside the boiler so fed, which has frequently caused serious damage. The plan of delivering the feed water in a horizontal direction, near the surface of the water, has been explained in previous reports; recent experience has still further illustrated the necessity for its adoption. Many boilers suffer seriously from the sediment deposited by the water. Where the use of bad water is unavoidable, I would advise that means be taken to precipitate the sediment in tanks before it enters the boilers. If the deposit is of a muddy character, a large settling reservoir, or filter bed, will be serviceable. The corrosive effect of acid water should be neutralised before passing it into the boilers. In order that the desired object may be effected with certainty and economy, the water should in each case be subjected to careful analysis by a competent chemist. Boilers about to be cleaned should be allowed to cool down before the water is let out. Neglect of this may lead to fracture of the seams, and render the scale more difficult of removal. with, as the grease from the cylinder often combines

#### WOOD WORKING MACHINERY.

MESSRS. S. WORSSAM AND CO., of the Oakley Works, Chelsea, have just issued a trade catalogue, which is well worthy of rather more than a passing notice. It is becoming the custom of engineering firms to issue something more than the mere trade price-list of former times We now have by us several examples of judiciously arranged catalogues, which give information upon the subject of the special manufacture which it is the object of the catalogue to advertise. The latest addition to these is Messrs. Worssam's, in which we can investigate the most recent improvements in the various machines in use for wood-working, and, at the same time, have rules placed before us for calculating the diameters of riggers and speed of shafting best adapted for the machinery illus-

trated. Besides this, there are rules in connection with the working of steam engines, which may be found useful in the absence of more special works. To enumerate all that Messrs. Worssam's catalogue contains, would be to detail the contents of some sixty well filled and amply illustrated pages. It will, therefore, be more to our purpose and to the interest of our readers to generalize the productions of Messrs. Worssam and Co., and to illustrate one or two items worthy of more special notice. The machines for which this firm has been so long and justly celebrated are saw frames, saw benches, builders and joiners' machinery of every kind, band saw machines, planing and moulding machines, machinery for railway plant, steam engines, &c. To these we may now add machinery for working in stone, marble, and slate, as well as sundry other apparatus.
We have selected for illustration Messrs. Wors-

sam and Co.'s improved acting saw bench with rope feed, and their saw sharpening machine. The saw bench is adapted for cutting logs, planks, deals, battens, &c., and is provided with an improved self-acting rope-feed motion, for advancing the timber to the saw. When cutting long stuff, carriages, running on rails at each end of the machine, are used to support the overhanging ends. The main standard of the machine is cast in ) a > piece, and the drum, around which the rope winds, being of larger diameter than usual, revolves less quickly, and, consequently, the injurious strain and twist on the rope are much reduced. To keep the stuff well up to the fence, a pressure lever with rollers and weights is supplied with each bench. The rate of feed may be varied from 15ft. to 60ft. per minute, according to the nature of the timber under operation. The object of the saw sharpening mechine we have illustrated in to leave as much machine we have illustrated is to lessen as much as possible the cost of saw sharpening, which forms so considerable an item in saw-mill expenditure. The file is almost entirely dispensed with, and a

disc of consolidated emery employed. The disc revolves on a spindle, carried by a counterbalanced arm that can be set to various angles, to suit the form of tooth required, and for gulleting, topping, bevelling, &c. For sharpening mill-saws, a long vice, with compound table, is affixed to the forepart of the machine, and is subject to the several variations of position necessary to bring each tooth When of the saw within reach of the cutter. circular saws have to be sharpened, the mill-saw vice is removed, and replaced by one shown in the We understand that this machine is coming into extensive use, on account of the saving effected in time, labour, and files. One man, with the machine, will do nearly as much work as six with the file by hand. The disc is inexpensive, and its average duration in constant action is about two The catalogue from which our extracts are made is exceedingly well got up, and should be consulted by all who require machinery of the above class.

# ELECTRIC TELEGRAPHY IRRESPECTIVE OF TELEGRAPHIC APPARATUS.

By Mr. E. G. BARTHOLOMEW.

(Concluded from page 193).

THE conductor of a submarine cable is invariably copper. It has been attempted to introduce those wires whose function is to take the strain off the copper into combination with it, and so by increasing its area to reduce its resistance, but this has only been done experimentally, and is not regarded with favour. It may therefore be assumed that the conductor is in all cases copper. Its high specific conductivity permits of a small section, and the small surface which this involves means decreased inductive area-a point which has been shown to be of paramount importance. weight of a copper strand of 7 wires-6 round 1is as compared with a solid wire of equal diameter, as 54 to 69.

The conductivity of copper varies immensely, the difference being traceable entirely to the admixture of foreign matter. Pure copper being regarded as 100, the addition of 2.45 per cent. of silver—an equally good conductor—conductivity to 82.52. An addition of reduces its An addition of 5:4 per cent. of arsenic, a metal frequently found in combina-tion with it, roduces its conductivity to 6.42. Some specimens of Spanish coppor, owing to the presence of arsenic and other impurities, conduct no better than iron. The existence of these facts has pointed out the necessity for adopting a standard of R in testing copper for electrical purposes. What this standard is may perhaps scarcely be said to be definitely settled yet. It has engaged the attention of a committee of the British Asso-ciation for several sessions. The standard of R in former use was equal to one mile of No. 16 copper wire pure, which was regarded as a unit, but the British Association has deemed it advisable greatly

to reduce this unit of measurement.

Whatever standard isadopted, temperature must be carefully considered. A rise of 4 deg. Fah. causes a loss of 1 per cent. in the conductivity of copper. Alloys vary very much less under changes of temperature than pure metals, and hence an alloy is the best material to employ in the construction of a standard, or in the making of artificial resistances. German silver, an alloy of copper, nickel, and zinc, is an excellent material for the purpose.

All cable cores-by which are meant the conductor and its insulating wrapper only-both before and after covering them, should be kept submerged at a temperature as nearly that of the ocean at great depths as possible; this is 39deg. Fab. By the adoption of this precaution, faults occurring during the manufacture are at once detected. The desirability of keeping the completed cable permanently submerged is shown from the fact that the Malta and Alexandria cable of 1861, covered with 18 No. 11 iron wiros, was coiled after completion into leaky tanks, the water being occasionally renewed. The iron sheathing was, therefore, alternately wet and dry, and the result was such a rapid oxidization of the metal that it generated heat to the extent of 86deg. Fah. Such a result should be carefully avoided, because, if gutta-percha be employed, it becomes soft at high temperatures, and if in this state the core is bent, the copper strand is liable to become decentralized, even if it does not-as has more than once occurred-altogether protrude from the gum.

The uncovered core of a cable should never be subjected to a high strain. If stretched, the copper will permanently elongate, whilst the percha will,

to a certain extent, return to its former length. The result of this is that the copper will buckle, and alter its position. If the outer wires are on the elongation is presented to any serious extent. With respect to the elongation of iron wire, it may be mentioned that No. 8 gauge will vary from 10.5 to 11.16 per cent. before it breaks. The softer the wire the more it will elongate, and the less strain it will bear.

Subterranean wires, it has been shown, being under the same laws of induction as submerged wires, manifest the phenomenon to an equal extent. The conductor is always copper, covered either with gutta-percha or india-rubber, and prospirally and passed through tar, and plentifully sprinkled with sharp sand before the tar solidities. The sand adheres to the surface embedded in the tar, and forms an admirable protection to the whole. If the wire in this state b brick, it will saw the brick in two. If the wire in this state be drawn over a

It is usual to protect buried wires, when laid under streets, by drawing them through iron pipes, but, in country roads, a stout wooden guttering may be sufficient. An economical plan, and one which answers well in some localities, is to take out a trench about 18in. deep, and to sift a portion of the thrown out soil back into the trench, then lay in the covered wires, and sift over them another portion of soil, laying upon this the larger and flatter stones, over which the remainder of the soil may be thrown and rammed in.

The advantage of test boxes at intervals along a length of buried wires is doubtful. They may, and do, present facilities for dividing the circuit without breaking the wire; but every test box is more or less a source of leakage, a loss of insulation. Ground test boxes are decidedly objectionable; upright boxes are better. The position of a fault, not of continuity, but of insulation, may be very closely calculated, provided the elements of the core are well known previously. It resolves itself into a question of R, which is proportionate to distance.

A few general remarks upon the submergence of cables may be instructive. This is an operation in which too much care cannot be taken. Remembering that whether the operation be a long or a short one, every moment of the time the cable is going overboard is a moment fraught with risk to the enterprise, it is evident that no precaution should be omitted, the neglect of which would endanger the cable. Every means should be adopted to prevent a stoppage in the paying out, or even a diminution in the speed of the cable, and the deeper the water, the more urgent is this pre-Great attention must be paid to the dynamometer, so that, the breaking strain of the cable being known, an ample margin may be given the brakes. But, after all, no positive rule can be laid down for the paying out of a cable. A man of ability will adapt his arrangements to the requirements of the situation, which will vary with weather, depth of water, and casualties which may, and indeed must arise. A general rule may, however, be laid down which applies particularly to great depth of water, which is, that the safety of the cable when being paid out is increased by an increase in the ship's speed, provided always that the staff of cable men can keep pace with the speed at which the cable travels. The more rapidly a cable leaves the ship, or rather the more rapidly the ship leaves the cable behind, the greater will be the angle between it and the perpendicular over the stern. The cable lies more horizontally upon the water, it sinks less rapidly, and requires less pressure to be applied to the brakes. self-evident conclusions.

The successful laying of cables in 2,400 fathoms, and, above all, their successful recovery in like depths, affords a sufficient proof that no difficulties, not surmountable, need be feared in the laying of any future cables in fathomable depths; but when we come to speak of the permanence of cables, however successfully laid, the aspect of things becomes changed. No guarantee can be given in this respect.

The character of the ocean's bed varies immensely. In the Mediterranean, the unevenness and inconstancy of the bottom in the volcanic area has proved singularly fatal to the continuance of cables. On this account, great judgment is needed in the selection of a suitable route by careful pre-vious soundings. The bottom of the Atlantic between Ireland and Newfoundland proved to be eminently adapted to the reception of a cable. For 28deg. of longitude the depth of water varied, with

upon a microscopic examination, to consist of minute shells. The presence of these shells has been regarded as a satisfactory proof that at the great depths of the ocean the water is in a state of rest, and that any cable being once laid there will remain undisturbed. The landing place of a cable is, however, a different thing altogether. However strong and well protected in itself the shore end of a cable may be, it cannot withstand the incessant beating of heavy waves upon a rocky coast. The Channel Islands telegraph cable is a remarkable instance of this fact. It may often be advisable to deviate considerably from a direct line in order to secure a better and more sheltered spot for the landing. But it is not only close to the shore that a cable is in danger. Even in water of from 100 to 200 fathoms a cable is not secure from the abrasion of icebergs of high specific gravity, and there seems little room to doubt that the only accidents which have occurred to the present Atlantic cables are due solely to these monsters

A rapid tideway should be avoided for the bed of a cable. The rust, which unavoidably forms upon the external wires, instead of accumulating and in time preventing further corrosion, becomes washed off, until the entire wire is gone. In some situations, cables become silted up with sand and shingle, and cannot then be raised for repairs. The adhesion of weed, coral, and other marine organisms, is detrimental to a cable, as facilitating its corrosion. The cable across Bass's Straits was actually floated by the mass of weed which enveloped it, although this cable weighed two tons per mile. Lastly, as far as possible, any frequented roadstead should be avoided, for a ship's anchor is a deadly enemy to telegraph cables, and all notices as to anchoring will stand for nothing in a gale of wind, setting on shore. The only remedy for this, if such a locality cannot be avoided, is to take the bull by the horns, and put down a cable to which any ship of ordinary tonnage may ride with the risk rather of breaking her own rope than the telegraph cable.

#### INSTITUTION OF NAVAL ARCHITECTS.

THE meetings of the Institute of Naval Architects, Session 1869, will be hold in the hall of the ociety of Arts, John-street, Adelphi, on Thursday, Society of Arts, John-street, Adelphi, on Thursday, March 18, morning at 12, and evening at 7 o'cleck; on Friday, March 19, morning at 12, and evening at 12 orly. The Right Hon. Sir J. S. Pakington, Bart, M.P., G.C.B., D.C.L., President, will occupy the chair. The council of the Institution will meet in the library of the Society of Arts at 11 a.m., on Thursday, March 18; and at 11 a.m. on Saturday, March 20.

Thursday, March 18; and at 11 a.m. on Saturday, March 20.

The following is a programme of proceedings, which, however, is issued subject to revision:

—Thursday, March 18.—Morning Meeting at 12 o'clock.—1. Annual report of the council. 2. Address by the president.

The following papers will then be read and discussed:—1. "On the Law of Resistance of Armour cussed:—I. "On the Law of Resistance of Armour Plates, composed of one or more thicknesses." By William Fairbairn, Esq., C.E., LL.D., F.R.S., Honorary Associate. 2. "On the Iron Floating Dock at Carthagena." By George R. Rennie, Esq., M.L.C.E., Associate. 8. "On Floating Docks." By Edwin Clark, Esq., C.E. 4. "On a Project for a Floating Dock." By Charles H. Wigram, Esq., Member of Council.

Member of Council.

Evening Meeting at 7 o'clock.—1. "On the Calculation of the Stress in Propeller Shafts." By W. J. Macquorn Rankine, Esq., C.E., LL.D., F.R.S., Associate Member of Council. 2. "On the Resistance opposed by Water to the Motion of Vessels of various forms, and the way in which this varies with the velocity." By John Isaac Thornycroft, Esq., C.E., Associate. 3. "On Railway Communication across the Sea." By John Scott Russell, Esq., F.R.S., Vice-President.

tion across the Sea." By John Scott Russell, Esq., F.R.S., Vice-President.
Friday Morning, at 12 o'clock.—1. "On Long and Short Ironclads." By E. J. Reed, Esq., C.B., Vice-President. 2. "On a New System of Ironclad Vessels." By Herr Josef Romako, Chief Constructor of the Austrian Navy, Member. 3. "On the Hydraulic Steering Apparatus now being fitted to H.M.S. 'Achilles.'" By Captain Inglefield, R.N., F.R.S. 4. "On the Steam Steering Apparatus, fitted in the 'Great Eastern,' and H.M. Ships 'Northumberland' and 'Monarch.'" By James Mac Farlane Gray, Esq.

'Northumberland' and 'Monarch.'" By James Mac Farlane Gray, Esq.
Friday Evening, at 7 o'clock.—1. "On the Qualities of Boiler Plate." By S. M. Saxby, Esq., R.N., Associate. 2. "On Liquid Fuel." By Captain Selwyn, R.N. 3. "On a New Life Buoy." By Staff-Commander Bourchier, R.N.
Saturday Morning, at 12 Selector.

Saturday Morning, at 12 o'clock .-- 1. "On Copper very trifling exceptions, from 2,000 to 2,300 fathoms, and the bottom, with equally trifling exceptions, consisted of a species of ooze, found,

Member of Council. 2. "On the Location of Inde-

pendent Steam, Fire, and Bilge Pumps in Steamers."
By Charles H. Haswell, Esq., Associate.
The above programme only reached us on Monday last, and of course several of the papers will have been read by the time this reaches our readers. We shall, in our next, commence our usual notice of the subjects discussed. subjects discussed.

# THE COAL AND IRON WORKS AT ROUND OAK.\*

THE COAL AND IRON WORKS AT ROUND OAK.\*

THE Earl of Dudley's iron works at Round Oak are situated on the high road between Dudley and Brierly Hill, and are, without doubt, the most and Brierly Hill, and are, without doubt, the most complete in South Staffordshire, regularly turning out a quality of iron unrivalled by, if not superior to, the production of any works in the Black Country. We arrive at this great establishment by the West We arrive at this great establishment by the West We arrive at this great establishment by the West Which runs parallel with one angle of the works. Midland division of the Great Western Railway, which runs parallel with one angle of the works, which runs parallel with the North-Western Railway, and twelve locomotive engines are employed to serve these works, thereby rendering assistance also over 40 miles of railway, which traverse his lordship's collieries. The works, together with the offices, &c., cover 30 acres of land, and they are capable of turning out from 500 to 550 tons of best finished iron per ing out from 500 to 550 tons of best finished iron per week. There are nine steam engines in the mills and forges, all working vertically or horizontally, and are very large steam hammer, with the last improvements, which is capable alike of dropping a 20-ton blow or cracking a nut without bursting the kernel. Here they have four large forge hammers or helves, and this is the only method adopted to form the puddled balls into blooms or slabs, as they may be required. Old fashioned shingling is the practice here; neither squeezers nor patent shingling of any kind is resorted to.

There are five rolling mills—one 16-inch plate

Here they have four large forge hammers or helves, and this is the only method adopted to form the puddled balls into blooms relabs, as they may be required. Old fashioned shingling is the practice here; neither squeezers nor patent shingling of any kind is resorted to.

There are five rolling mills—one 16-inch plate mill, a 12-inch ditto, an 8-inch and 7-inch bar mill, in these works—is admirable for its extent and convenience. The speeds are higher than anything in South Staffordshire, and the machinery, by its quiet and steady motion, forcibly reminds one of the saying that the construction and perfection of the saying that the construction and perfection of the saying that the construction and perfection of the saying which drives all the mills and forges supersedes gear which drives all the mills and forges supersedes gear which drives all the mills and forges supersedes gear which drives all the mills and forges supersedes sity is very rapid, but the sound resembles the engines run fast, the nut on the fly shaft of necessification in the saying should be a selegic hammer of the cap work of the superseder in the control of metal with metal in their constant revolutions. Where no head with the truth of all the driving wheels are large, and as the head of the saying sounds like a sleege hammer on the cog of a wheel, which are generally heard in the or works of the Black Control. We were much struck with the truth of all the driving wheels; indeed, the general lines of the work reminded us of a parallel, general lines of the work reminded us of a parallel, and the properties of the securities distribution of metal in their orners and rightly placed. We could not always square and rightly placed. We could not always square and rightly placed. We could not always square and rightly placed. We could not alway square and rightly placed. # A NEW TANK LOCOMOTIVE.

A NEW TANK LOCOMOTIVE.

A LOCOMOTIVE with some novel features, designed and patented by Mr. M. N. Forney, designed and patented by Mr. M. N. Forney, at the Hinkley and Williams Works in Boston, has recently had a trial on the Chicago, Burlington and recently had a trial on the Chicago, Burlington and Railway In designing this engine, says the Quincy Railway. In designing this engine, says the American "Railway Times," Mr. Forney has aimed to secure some decided advantages over the common locomotive, by a better distribution of the weight on the wheels, and it is claimed that he has accom-

witching engine, weighing 20 tons, will draw as much as an ordinary eight-wheeled truck engine, weighing 30 tons. The weight of the switching obvious; as the whole weight wheeled truck engine, weighing 30 tons. The weight of the switching engine is carried by the four driving-wheels, whereas only about two-thirds of the weight of the eight-wheeler is on the driver, the other third being carried wheeler is on the driver, the other third being carried on the truck. It might, therefore, very naturally be asked, why the four-wheelers are not used for general afreight business? The shortness of the wheel base, and consequent unsteadiness of the engine on the track is the great difficulty. Mr. Forney has aimed to secure a long wheel base, and at the same time, retain all the weight of engine and boiler on the drivers. To do this, he has arranged the engine proper, exactly as a common four-wheeled switcher, and then extended the frames beyond the firebox, which is carried on a four-wheeled switcher, and then extended the frames beyond the firebox, and then extended the frames beyond the firebox, and then extended the frames beyond the firebox, the which is carried on a four-wheeled switcher, and then extended the frames beyond the firebox, and then true to create a prejudice against the engine; sight, is apt to create a prejudice against the engine; sight, is apt to create a prejudice against the engine; but the objections to this crab-like movement are but the objections to this crab-like movement are bring in the opposite direction.

First, and most important of these, is the fact that the truck—which can adjust itself to the curvature of the going of Mr. Forney's engine.

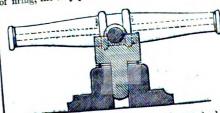

First, and most important of these, is the fact that the truck—the damped of the product of the product

A TWIN GUN.

A TWIN GUN.

SIR,—Enclosed I beg to send you a design for au 8-inch twin gun, 11ft. length of bore, which may be of cast or wrought iron in one solid mass of metal. It is mounted on trunnions as usual, and has a pin swivel or other turntable. The advantages of this swivel or other turntable. The advantages of this gun are that one barrel is charged instantly on the discharge of the other. The fire, therefore, will be at least as quick as that of any breechloader, and the artillery men and gunners will never have to turn their backs on the enemy. The recoil will be scarcely sensible, because the centre of gravity, the homogeneous centre of the mass, and the centre of resistance, will all coincide in one point, in addition to the immense mass of metal, here usefully employed, situated behind the bottom of the chamber in the act of firing, the only preventive of excessive recoil.

Some leverage and appliances will be required for elevation and depression, because the barrels will not be equally balanced by the charges. The friction, from the great weight upon the steel rollers, or upon whatever turntable be adopted, may be relieved by hydraulic pressure upwards upon the centre pin. The revolution of the twin gun takes place at about

8ft. above the platform, and therefore well clears the heads of the artillery men. It will occupy no more space on the platform than usual with guns of this calibre.—I am, Sir, yours, &c.,
HENRY W. REVELEY, C.E.

1, Baker-street, Reading, March 8.

#### DETERIORATION OF SUBMARINE CABLES.

SIR,—Your remarks upon my pamphlet on telegraph companies, in your paper of the 12th inst., are, I consider, extremely fair, and calculated to advance telegraphy; but I should like to make a few observations upon some portions of your article.

You say that the money spent on renewing land lines keeps the property always at its full value, but liues keeps the property always at its full value, but you do not prove that repairing a submarine cable does not do the same. You state that a submarine cable is gradually and surely depreciating. Now, this is mere theory; for some, if not all, of the cables laid by the originator of submarine cables (the famous Mr. Brett), and the first of which was laid in 1851, are still in existence, and, whenever picked up, are found to be in a most perfect state of preservation; besides which, the manufacture of submarine cables has been very greatly improved since the days of Mr. Brett.

You object to my characterising the Persian Gulf route to India as "almost useless," because communication has been well and satisfactorily carried munication has been well and satisfactorily carried on by means of this route for several years. I think, on referring to different reports that have appeared on the subject, you will find that a message, on an average, does not go very much quicker than if sent by post, and certainly those reports prove that a submarine line is at least worthy of a trial.

You say, "But, unfortunately, the author quite forgets that the arguments he appears to think so strong against the line from Bombay to Suez are stronger against the proposed scheme." This remark seems to me rather vague; might I ask you to explain your meaning more fully?

remark seems to me rather vague; might I ask you to explain your meaning more fully?
Lastly, allow me to say I am very sorry if I appear to have been "running down" different schemes. My only object in mentioning companies that I did not consider good investments was to put them in contradistinction to companies which I do think worth investing in, and so making my pamphlet really useful to investors.

Hoping you will find space for these remarks,—I am. Sir. yours. &c..

am, Sir, yours, &c.,

J. WAGSTAPF BLUNDELL

J. WAGSTAFF BLUNDELL.

49, Chancery-lane, London, March 16.
[The remarks we made relative to the gradual depreciation of submarine cables, so far from being "mere theory," were founded on facts known to any one with the least protension to acquaintance with submarine cables. We will simply take the special cable mentioned by Mr. Blundell, as an example, although many others could also be taken—the Dover and Calais cable, laid in 1851. Up to the present time this cable has been repaired about thirty or forty times, and in consequence of the present time this cable has been repaired about thirty or forty times, and in consequence of the breakages and numerous repairs necessary owing to the deteriorated condition of the cable, renewals to such an extent have been necessary that there is now only a little more than one half of the original cable down. We recommend Mr. Blundell (as he probably cannot see the cable himself), to refer to the Government Report on Submarine Cables, 1861. He will there find a very faithful and exact illustration of a specimen of the above cable. Cables, 1861. He will there find a very faithful and exact illustration of a specimen of the above cable, as it was ten years ago; his opinion on the perfect state of preservation of cables may probably undergo a change. We objected, and still do so, to Mr. Bluudell's sweeping assertion of the "almost useless" condition of the Persian Gulf line. If such had been the case, no business would have passed over it. The returns gradually show an increasing business.—ED. M. M.]

#### PERPETUAL MOTION.

SIR,—I shall be extremely obliged if you can inform me if it is correct that Government has offered a reward for the discovery of perpetual motion, what conditions are specified (if any), and what the amount of the reward is.—I am, Sir, yours, &c.,

J. EMERSON RUSSELL.

J. EMERSON RUSSELL.

11, Vincent-terrace, Islington, N., March 15.

[We are not aware that Government has done anything so foolish as to trouble itself about a question which is practically valueless; and we are astonished that there are still people to be found who can think twice upon the subject.—ED. M. M.]

WED.—Civil and Mechanical Engineers' Society.—Mr. Henry J. Rogers on "The Capture of Whales and other Fish by the Application of Electricity," at 8 p.m.

### Habal, Military, and Gunnery Items.

Mr. J. S. MACKIE will deliver a lecture on the Shoeburyness experiments in 1868, at the Royal United Service Institution this afternoon.

AT a special court held on Tuesday, at the Trinity House, Tower-hill, his Royal Highness the Prince of Wales was unanimously elected an elder Brother of the Corporation, in the vacancy occasioned by the death of Admiral Robert Gordon.

WE regret to have to announce the death, on Tuesday night, of Major-General John William Ormsby, R.A., the lieutenant governor and commandant of the Royal Military Academy at Woolwich. He was seized with a paralytic stroke on Tuesday afternoon, and died during the night.

THE death is announced of Admiral Sir Peter Richards, K.C.B, formerly one of the Lords of the Admiralty. The deceased was on the reserved half-pay list. He was made captain September 17, 1828; rear admiral, June 6, 1855; vice admiral, on April 12, 1862; and admiral, on September 12, 1865.

The Trinity Board has resolved to supersede the Longships lighthouse off the Land's End by a new structure on an adjoining rock. The contract for the granite work has been taken by a French firm, and all the granite for the work will be imported from France. The picking out of the foundation will commence at once. will commence at once.

THE British Consul at Charleston, Mr. Walker, warns shipmasters that the charts of that port published by the Admiralty, corrected to March last, are very inaccurate. The errors have been pointed out for correction, and masters trading to Charleston should supply themselves with Admiralty charts of a date subsequent to "III. 68."

At the last weekly meeting of the Mersey Docks and Harbour Board, a report from Admiral Evans, the Conservator of the Mersey, was read, from which it appearedthat in 1868 there was a decrease of 3,114 in the number of vessels entering and leaving the port, compared with 1867, but the tonnage showed an increase of 20,571 tons.

THE first steam boat, the propeller "John L. Hasbrouck," forced her way through to Poughkeepsie, on the Hudson, on the 25th ult. She broke through 6in. of solid ice for a distance of nine miles. While she was working in the middle of the river, just south of Poughkeepsie, crowds of persons ran ahead and by the side of her on the ice.

A suspension of the manufacture of the Palliser A SUSPENSION of the manufacture of the Palliser chilled shot has been ordered in consequence of a report made from Shoeburyness of the breaking of several of them in the bore of the gun when fired. It appears that the stud or bouche at the sides near the bottom of the shot are forced in by the explosive power of the powder, which breaks and destroys the missile, and until this defect can be remedied no more will be made.

THE committee which was appointed by the States of the Island of Jersey in September, 1866, to examine the various plans and estimates submitted to examine the various plans and estimates submitted for improvements and additions to the existing harbour of St. Helier, have arrived at the end of their duties, and have awarded the first premium of £300 to Mr. John Coode, C.E., while the second and third premiums of £200 and £100 have been assigned to Mr. A. Giffard, C.E., and Mr. W. R. Kinipple, C.E., respectively. About 40 different designs were sent in.

dipping old Armstrong shell cases into a cauldren of boiling lead, for the purpose of melting off the lead in which the shells are encased. A shell tead in which the shells are encased. A shell which had been charged was so treated, when an explosion took place, scattering the boiling lead over the three men employed, inflicting deep and agonising injuries. One of the sufferers had lost an eye by an accident some years ago, and now has lost the other. Their lives are in jeopardy.

The first stone of the new works for the extension of Portsmouth dockyard was laid yesterday week. A block of Portland stone, weighing some five tons, was fixed at one end of a vast excavation, which will form one of four docks that will stand on the south side of the new repairing basin included in the general plan of the extension works. A silver trowel, together with a square, plumb-line, &c., were handed to Mrs. Wellesley, who performed the duties of master mason, and declared the stone well and truly laid. A few words were then spoken by Rear-Admiral Wellesley, and a great engineering work was formally commenced. Tup first stone of the new works for the extension work was formally commenced.

The death of Admiral Sir Charles Christopher Parker, is announced as having taken place on the 13th inst. The gallant admiral was the third son of Vice Admiral Christopher Parker, who was eldest son of Sir Peter Parker, first baronet. He was born in 1792, entered the Royal navy at an early age, served in the Mediterraneau, at the capture of the Island of Capri, at the defence of Gaeta, and in an attack on a convoy off Cape Talliat. He was lieutenant of the "Malta" at the siege of Tarragona, and has been an admiral on the reserve list since 1863. The first baronet was for upwards of 80 years in the navy, and greatly distinguished himself in the American war; the second baronet was a captain in the navy, and was mortally wounded at the storming of the American camp at Bellaire, near Baltimore; the third baronet was a commander, the fourth was a captain, and the deceased baronet was an admiral. The baronetcy was created in 1782, so that within 90 years no less than five baronets have served their country in the naval service. THE death of Admiral Sir Charles Christopher

A WRITER in "Harper's Magazine" for the present month attempts a calculation of the number of lives lost on the United States coast and in American lives lost on the United States coast and in American vessels by shipwrecks, but there do not appear to be means of testing such a calculation. He estimates the loss at about 30 persons per week, or about 1.500 a year. More trustworthy is the following list of wrecks of American vessls in the last ten years, and the value of the property lost. In 1858 the number was 355, and the value of the property lost 8,897.665dols.; in 1869 (9 months) 300, and 42,897.665dols.; in 1869 (11 months) 405, and 12,011,030dols.; in 1861, 558, and 17,367,100, dols.; in 1862, 452, and 12,765,060,dols.; in 1863, 452, and 20,531,800dols.; in 1864, 495, and 20,449,850dols.; in 1865, 502, and 33,794,300dols.; in 1866, 471, and 31,056,100dols.; in 1867, 536, and 21,742,200dols.; in 1868, (9 months), 257, and 11,698,500dols. The total for 10 years and 5 months is 4,883 vessels wrecked, and the property lost, 198,702,876. This gives an and the property lost, 198,702.876. This gives an average daily loss nearly equal to one-and-half vessel, and in value 54,000dols.

#### Miscellanea.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending March 13, was 3,868. Total number since the opening of the Museum, free daily (May 12, 1858), 1.519.504.

At the ordinary meeting of the Society of Engineers, held on the 15th inst., Mr. F. W. Bryant, President, in the chair, a paper was read on "Joints for the Prevention of Leakage in Gas and Water Mains," by Mr. C. M. Barker.

WE have to record the death of Sir John Peter boileau, at Tor quay, on Tuesday week. He was born on the 2nd of September, 1794. Sir John had been a Fellow of the Royal Society since 1843, and was vice-president of the Society of Antiquaries.

WE understand that Her Majesty has signalised We undersumd that Her Majesty has signalised her accession to the list of Royal and noble authors by becoming patroness of the Booksellers' Provident Institution, and has testified her sympathy with its objects by a substantial donation to its funds.

THE French Academy of Sciences, at its last meeting, elected Dr. David Livingstone a corresponding member of that body in the section of geography and navigation, in place of the late Mr. Dallas Bache, of Washington.

The shock of an earthquake was felt on Monday evening throughout East Lancashire and West Yorkshire. The tremor was perceptible as far Yorkshire. The tremor was perceptible as far south as Manchester, and the Scotch papers record similar phenomena in the Highlands.

At a recent meeting of the curators of the Univerity of Edinburgh, a letter was read from Professor Lyon Playfair, M.P., intimating his intention to resign the chair of chemistry at the close of the present session. There are already a Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the Woolwich Arsenal. Three men were employed in number of candidates for the professorship.

THE council of the Royal Cornwall Agricultural Society have decided to hold the exhibition in 1870 at Launceston. This year's meeting will be at Penzance, and there is already promise of an exceedingly good one. The prizes offered exceed by £100 the amount in any previous year.

by £100 the amount in any previous year.

For the first time in its history, the House of Representatives, on February 27, listened to a speech from a negro. This negro, John W. Menard, claimed a seat from Louisiana, and spoke over an hour in advocacy of the claim. The House refused to admit him to membership, but voted him 1,500 dollars to pay his expenses at the capital, where he has been sell the winter. all the winter.

THE first spring show of the Royal Horticultural Society of the present year was held in the gardens on Saturday last. Such a collection of hyacinths, cyclamens, roses, and other spring flowers has never before been seen at South Kensington. The Dutch growers gave supplemental prizes amounting to £45, which caused a very keen competition among the various exhibitors. There was a very large and fashionable attendance.

THE number of visitors to the South Kensington THE number of visitors to the South Kensington Museum during the week ending March 13, 1869, was—on Monday, Tuesday, and Saturday (free) from 10 a.m. to 10 p.m., 13,655; Meyrick and other galleries, 2,438; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 5 p.m., 1,954; Meyrick and other galleries, 217; total, 18,264. Average of corresponding week in former years, 10,500. Total from opening of Museum, 8,229,124.

10,000. Total from opening of Museum, 8,229,124.

The area of London, as defined by the Registrar General, and including extensive suburbs, is about 78,000 acres, or nearly 122 square miles. On this area stand over 400,000 inhabited houses, with an average of nearly eight persons to a house, giving a mean density of 40 persons to an acre. The estimated population at the present time is 3,126,635.

The county rate assessment of 1866 placed the annual value of property in London at £15,261,999.

An explosion took place on Monday morning at An explosion took place on Monday morning at Messrs. Kynveh's cartridge and percussion cap manufactory, Aston, near Birmingham. Girls were employed in one of the processes connected with the charging of the cartridges. These cartridges were drying upon a hot slab, and one of the girls were brushing them off quickly with her hand, when the friction with the slab caused the explosion. Five girls were much burned in the face, and are now in the hospital.

now in the hospital.

An important question, opened some years ago between the Asiatic Society of Bengal and the Government of India, has at last been brought to a satisfactory conclusion. It is now agreed that the society shall hand over to trustees, appointed by the Legislative Council, their collections of natural history, antiquities, miscellaneous objects, and the additions that may be made thereto. The Government on their part undertake to erect a suitable building, to maintain a proper staff of keepers, and to provide for all the charges of such a museum. a museum.

The oldest tree on recordin Europe is asserted to be the Cypress of Somma, in Lombardy, Italy. This tree is believed to have been in existence at the time of Julia Cæsar, 42 years before Christ, and is therefore 1,911 years old. It is 106ft. in height, and 20ft. in circumference at 1ft. from the ground. Napoleon, when laying down his plan for the great road over the Simplon, diverged from a straight line to avoid injuring this tree. Superior antiquity is claimed for the immense tree in Calaveras County, California. This is supposed from the number of concentric circles in the trunk to be 2,565 years old.

An extraordinary case of trance is reported from THE oldest tree on record in Europe is asserted to be

circles in the trunk to be 2,565 years old.

An extraordinary case of trance is reported from Burlington, Wisconsin. A little German girl had an attack of measles and diphtheria, from which she had nearly recovered on the 8th ult., when she fell into a state of coma, and has remained for 20 days without food and to all appearance lifeless. The heart seems to have ceased its pulsations, but blood flows from the veins if opened, the flesh is firm and fresh-looking, and a blister applied will act. Though the body has been enshrouded and placed in a coffin, its interment has been delayed to wait the results of further developments.

A short time ago. says the "Mining Journal."

the results of further developments.

A short time ago, says the "Mining Journal."
Pascoe Ellis, a young man working in the 180 fathom level east in Botallack mine about half a mile from the sea, after blasting a hole in a hard granite rock (not primary, but what is called the secondary granite), about 8in. off from a lode composed of quartz and iron, and 5ft. thick, discovered a substance, jutting up 3in. above the surface of the rock he had blasted. He took his hammer to break it off; but, on finding it flexible, with his chisel he cut it out. It proved to be a vegetable substance, about 4in. in length and 1jin. in diameter. It had the smell and appearance of the common orewed, found on our shores. What can geologists make of this fact?

A PORMEE manufacturer of whips in Birmingham oused of quartz and iron, and 5ft. thick, discovered a substance, jutting up 3in. above the surface of the rock he had blasted. He took his hammer to the rock he had blasted. He took his hammer to the the substance, about 4in. in length and 1lin. in diameter. It had the smell and appearance of the common oreth had the smell and appearance of the common oremake of this fact?

A FORMER manufacturer of whips in Birmingham has started a whip factory at a place called Footscray, in Victoria. He found a great local demand

for whips, and also that several of the raw materials for whips, and also that several of the raw materials which the manufacture required could be obtained at Footscray for an almost nominal cost. The adjacent abattoirs supply him with an abundance of sheeps' intestines, from which he makes his catgut. The rattan cane, which enters largely into the interior of a whip, comes as dunnage in rice and sugar ships from India. With these and similar advantages, in spite of the scarcity and cost of skilled labour, it is found possible to supply the colonial market with a more suitable article, and at a lower price than English manufacturers.

a lower price than English manufacturers.

To the various paper productions of this paper age—paper collars, paper shirts, and even paper waistcoats, bonnets, and hats—must now be added paper coffins. M. Szerelmey, the patentee of these coffins, seems to have a belief in the universal adaptability of paper to all the needs of civilized life. His object in introducing it in the manufacture of coffins is to obtain what so many people rather absurdly consider a desideratum—a perfectly airtight, water-proof, and damp defying shell, which nothing from without can penetrate, and nothing from within can escape. The Zopissa paper coffin, in which these conditions are said to be fulfilled, is a solid-looking structure, very much resembling in build and thickness the ancient mummy cases

# Patents for Inbentions. ABRIDGED SPECIFICATIONS OF

PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared excludents of the force of the force of the Government, and are, therefore, the property of the Proprietors of this Magazine. 2648 J. DAWSON, Thames Ditton. Shaft tug. Dated August 26, 1868.

This consists of a metal hooked support for the shaft. It is connected to the back band of the harness, and is It is connected to the back band of the harness, and is nade with a flat surface crossways for a strap to bear against: plates, checks, or guards are fitted, and these may have one or more bars or cross pins, extending from the check on one side to the cheek on the other, to prevent the strap falling out of the channel formed for it, by the flat surface of the hook and the cheek.—Patent abandoned.

2649 S. MORRIS Lancaster. Spinning makes Dated.

surface of the hook and the cheek.—Patent abandoned.

2649 S. Morris, Lancaster. Spinning mules. Dated
August 26, 1868.

The running band is taken over a grooved pulley, fixed
on a shaft, and worked from the present driving apparatus or otherwise. On the rim drum shaft, or other shaft
connected therewith, is a pulley to which a brake is applied;
this brake is connected to a weighted lever, the position of
which is governed by the counterfaller. When the countertaller is depressed by the yarn, the brake is applied,
thereby checking the velocity of the spindles, according to
the thickness of the cop.—Patent completed.

2650 I. Hamer. Bolton. Looms. Dated August 26, 1868.

he thickness of the cop.—Patent completed.

2650 J. Hamer. Bolton. Looms. Dated August 26, 1868. This consists in providing an extra shuttle box, picking motion, stick, and weft-stop motions; in subdividing the lathe and the reed of the loom, into two parts; and in the sadaptation of anexirs or intermediate shuttle box, centrally situated on the "fly board," between the two ordinary shuttle boxes, which is open at both ends, and provided with check straps to prevent the concussion and rebound of the shuttle.—Patent abandoned.

2652 R. W. MORGAN, Dublin. Reaping. Dated August 26,

68.
The Lord Chancellor has granted an extension of time r filing the specification of this patent.

2658 W. HOUGHTON, Leeds. Looms. Dated August 26

This relates to the "weft-fork motion," or the apparatus employed to stop the action of the loom, when the weft becomes either broken or used up, and consists in fitting the rod or bar upon which the fork is hinged, arranged to slide in a bracket or bearing fixed to the breast beam of he loom.—Patent abandoned.

2654 W. L. WILLIAMS, Liverpool. Motive power. Dated August 26, 1868.

A cylinder is formed with ports and fitted with a piston, piston rod, valves, and a fly wheel, the whole being carried or supported on strong framework.—Patent abandoned.

2655 E. ZOEPFEL, Manchester. Window frames. Dated

2655 E. ZOEPFEL, Manchester. Window Frances
August 26, 1868.
To the threshold of the doorway is fitted a clip, which
row the threshold of the doorway is fitted a clip, which
serves to retain in position a tubular strip of caoutchouc,
having a longitudinal recess or groove in the side nearest
to the door. To the lower edge of the door is affixed a
moulding or bar formed with a projecting wedge-shaped
odge, the sides of the wedge being preferably curved, the
moulding being so fitted to the door, that when the door is
closed, the projecting edge of the moulding will enter the
recess or groove in the caoutchouc.—Patent shandoned.

closed, the projecting edge of the mouding will enter the recess or groove in the caoutchout.—Patent abandoned.

2656 S. B. SAMUELS and J. Birks, Nottingham. Woven fabrics. Dated August 26, 1868.

For this purpose the warp threads of the fabric are arranged to pass from the warp beams through eyes in a series of warp bars, like those of a bobbin net machine. An number of widths of fabric are produced simultaneously in the machine, and each warp bar carries one warp in the machine, and each warp bar carries one warp thread of each width. The warp bars are actuated by means of cams or jacquard, as in a bobbin net machine, and by means of them the warp threads of each width are divided so as to form a shed. A shed being thus produced, a loop of the thread which is to form the weft of the fabric is carried through it by a weft carrier, and then, on the further side of the shed, a bobbin or shuttle having a thread in it, is thrown through the loop, and the thread retains and carrier returns. The bobbin or shuttle thread retains and holds the loop of the weft thread so that on the return of the weft carrier a double weft is left in the shod.—Patent completed.

2657 J. HANSON, Lincoln. Firearms. Dated August 26

2657 J.HANSON, Lincoln. Firearms. Dated August 26
1869.

The patentee constructs the striker with a projection at its hinder end, extending outwards from it and entering a slot formed in the inner side of the hammer. The slot is so shaped that when the hammer falls it acts on the projection of the striker and throws it forward. In central-fire breech-loading firearms a small pin is arranged to slide in a hole in the rib between the barrels. The to slide in a hole in the rib between the barrels. The rear end or head of this pin is caused by a spring to project, and enters an annular groove or recess formed at the end of the barrel to receive the cartridge flange. When there is a cartridge in the barrel, and the breech is closed, the flange of the cartridge displaces the pin, pushing it forward against the resistance of the spring, and in order forward against the resistance of the spring, and in order that this change in the position of the pin may indicate the presence of a cartridge, there is a hole passing from the exterior into the passage in which the pin works, so that a small portion of the stem of the pin is exposed.—

2658 A. Lupton, Chesterfield. Boilers. Dated August 26

2658 A. LUPTON, Chesterfield. Boilers. Dated August 26

2658 A. LUPTON, CRESTERIER. Batter August 26
1868.

This consists in forming a chamber or compartment behind the boiler in the flue in which two passages are formed between the boiler and the chimney, the one passage being closed by dampers when the other is open, and rice versa. The larger of these passages or thoroughfares is provided with firebrick abutments, against which fares is provided with firebrick abutments, against which the fiames and products of combustion escaping from the furnace implinge, thereby effecting a high state of temperature in such chamber; an inlet valve for fresh air is provided in the heated chamber, which is opened during the time the passage through each compartment is stoped by the damper; at this time, a thorougafare or passage is opened between the heated air chamber and the front of the furnace over the "dead plate."—Patent abandoned.

2659 T. Weigley, Lancaster. Furnaces. Dated

of the furnace over the "dead plate."—Patent shandoned.

2659 T. WRIGLEY, Lancaster. Furnaces. Dated August 27, 1868.

This consists in the employment of firebars or grates arranged in two or more distinct sets, each set being lower than the one in front; these sets of grates are supported on rollers secured to the sides of the furnace upon which they are capable of sliding: each set of bars project beyond or overlaps the next set, the last set being placed over a stationary grate near the bridge, thus giving a stepolic formation to the grid or entire grate of the furnace. like formation to the grid or entire grate of the furnace in the patent of them by tappets or eccentrics, and rods, indeparted to them by tappets or eccentrics, and rods, indeparted to them by tappets or eccentrics, and rods, indeparted to the set of bars have forward and backward motion imparted to the set of the furnace of the first set of bars, being the highest, project from the first set of bars, being the highest, project from the front of the boiler, under a hopper, which is constantly kept supplied with coat. When the furnace is in action, the sliding bars are successively pushed forward, from the highest set to the cases very pushed forward, from the highest set to the lowest, after which they are withdrawn; the intermittent econstantly to carry and rush forward the coal from the hopper towards the "bridge."—Patent completed.

hopper towards the "pringe. — Patent completed.

2660 W. M. JACKSON and R. GARRIES, Kingston-upon-Hull. Roofing. Dated August 27, 1868.

This consists in forming tiles of such a sectional shape that one edge shall overlap that of the tile on right side of it, while the other edge may be overlapped by that of the tile on the left side of it.—Patent completed.

2661 E. PEYTON, Birmingham. Bedsteads. Dated August 27, 1868.
This consists chiefly in curving the head and foot boards or rails, so that the legs can be brought more under the bedstead.—Patent completed.

bedatead.—Patent completed.

2662 L. P. Hebert, L. A. Moulin, J. P. and E. Couinck,
Paris. Inking press. Dated August 27, 1868.

This consists of an ink box of the same shape as the
tamp, with a vertical tube at the centre and top thereof;
stamp, with a vertical tube at the centre and top thereof;
the ink box is formed in two parts. The upper one contains the ink, and in the lower a sheet of cork, and a piece
of felt in contact therewith; the division plate of the
box and the piece of cork are pierced with small holes

for the passage of the ink on to the felt.-Patent aban-

doned.

2663 D. Smith, New Jersey, U.S.A. Smoke consuming. Dated August 27, 1868.

Two horizontal bars are made to rest upon the existing dead plates which support the ordinary furnace bars. These two bars extend the entire length of and deeper than the furnace bars. The horizontal bars support a number of crossbars. The horizontal bars support a number of crossbars, formed and arranged with apertures or spaces between or through them, for the admission of air. Inside these crossbars perforated screens are arranged. The screens aid in heating and more evenly distributing the air which passes through the apparatus, and also prevent any danger of displacing the bars in raking the fire or introducing fuel into the furnace.—Patent completed.

2664 B. BURROWS, Loicester. Separating silk. Dated August 28, 1868.

August 28, 1868.

The skein of silk to be divided into two or more smaller skeins is placed over a rotating roller, the axis of which is supported in a bearing, in a suitable frame or support at one end only, the other end being free to admit of the skein being passed over it. The motion of the roller can be arrested from time to time by means of a treadle, and its position can be adjusted to adapt it for receiving various lengths of skeins. The lower end of the skein is passed around a lever arm mounted on a centre, at a suitable distance below the roller. The lever arm and roller are parallel with each other, when the skein is stretched over them, by the depression of the lever arm (which is constantly drawn downwards to a certain extent by means of a spring). A further depression of the lever arm puts constantly drawn downwards to a certain extent by means of a spring). A further depression of the lever arm puts additional tension upon the skein when required. The skein of silk thus stretched over the rotating roller and lever arm is first operated upon by the flugers of the operator, so as to open and spread out the skein upon the roller; a beating action is then imparted to the lever arm during the rotation of the roller and skein, which effectually opens and separates the skein of silk evenly over the surface of the roller.—Patent completed.

2665 N. J. Holmes, Regent's Park. Telegraph. Dated August 28, 1868.

This consists in a combination of parts which together form the magneto communicator. This communicator This consists in a combination of parts which together form the magneto communicator. This communicator proper is simply a mechanical generator or producer of currents from the magnet, the necessary succession of which are regulated by the elevation and depression of a series of finger keys or buttons, corresponding to the several letters or signs on the dial, and under the control of the operator. The apparatus does not in any way form a part of the telegraphic circuit, either as interruptor of the current, or as a short circuit connector. Its action is purely mechanical, and the currents from the coils of the magnet pass at all times directly into the telegraphic circuit. All insulation of parts and delicacy of adjustment is thereby avoided.—Patent completed.

2668 J. Tulk Glascow. Treating sewage. Dated

2666 J. Tule, Glasgow. Treating sewage. Dated August 28, 1868.

The patentice employs compressed air for transferring the sewage from closed receptacles into closed tank carts. The carts are furnished with air pumps, driven by horse gear, for compressing or exhausting the air employed.—Patent abandoned.

2667 W. STRANG, Glasgow. Treating sewage. Dated gust 28, 1868.

2667 W. Striagu, Classon.

The patentee provides a vessel at the lower end of a discharge pipe, with separate outlets for the liquids and solids combined, and interposes therein a filtering or separating medium of sufficient depth, through which the liquids can pass, but which keeps back the solids.—Patent completed.

Van Maldetone. Cleaning glores. Dated

2668 G. KER, 'Maidstone. Cleaning glores. Dated August 28, 1865.
This consists in submitting gloves to the action of rotating brushes or scrubbers, supplied with a cleansing divist. fluid.—Patent completed.

2669 T. HENDERSON, Glasgow. Sewing machines. Dated

2669 T. HENDERSON, Glasgow. Sewing machines. Dated August 28, 1868.
This consists in placing the needle bar in a guide, which oscillates on a centre fixed to the frame of the machine. To the needle arm or lever a pawl is fixed, which, as the arm or lever makes its upward stroke, catches into a tooth of a ratchet wheel, which it revolves through a certain angle. In the face of the ratchet wheel pins are fixed that act upon the long arm or lever, the shorter arm of the lever acting against the guide which carries the needle bar, so that each time one of the pins in the ratchet wheel lifts the short lever, it again acts upon the guide, which it oscillates through a small angle; thus, the point of the needle is guided alternately to opposite points in the cloth. needle is guided alternately to opposite points in the cloth.

—Patent abandoned.

2670 B. CORCORAN and P. W. DUNHAM, Mark-lane. Mill-

2670 B. COROBAN and P. W. DUNHAM, Mark-lane. Mil-stones. Dated August 28, 1868.

This consists, first, in adjusting a vertical shaft and boss in the eye of the milistone to be dressed. The shaft and boss supports a horizontal radiating arm, so constructed that it can be regulated and adjusted in such manner that the diamond cutter shall work in a true plane.—Patent completed. completed.

2671 R. SAUNDERS, Croydon, Breakeater, Dated August 28

1883.

The patentee proposes to moor a pontoon or series of pontoons to seaward of the waters to be protected. Means of access to the structures are arranged. They contain series of longitudinal vertical bulkheads of different depths.—Patent completed.

2672 W. M'GREGOR, Notting Hill. Signal posts. Dated August 28, 1868.

The posts are made of telescopic sections to slide one into the other, so that all may be packed into the lowest and largest section to facilitate their transport from place to place.—Patent abandoned.

2673 C. H. GARDNER, Fetter-lane. Printing machines

2673 C. H. GARDNER, Fetter-lane. Printing machines. Dated August 28, 1868.
This consists of a bar or rod carrying arms or plates made adjustable at required distances apart. Two or more of these arms are provided at the ends with adjustable bitts, plates, or pieces. These are set or adjusted on the arms by serews and slots to regulate and register the margin of the sheet while being printed. The gripper bar carries a number of arms, teeth, or times formed with holes through which the first-named bar is passed.—Patent complated.

2674 E. RICHARDSON, Wapping. Bottle cases. Dated August 28, 1868.

This consists in making bottle cases from a substance equisiting of "spent" hops reduced to a pulp, into which glue and treacle, alum and bichromate of potass, are mixed. The compound is rolled into sheets or pressed in moulds to the required shape.—Patent completed.

2675 H. POTTER, Belfast. Bleaching. Dated August 29,

This consists in the employment of superheated steam for bowking, boiling, or bleaching cotton and other fabrics and fibres.—Patent abandoned.

2676 J. MARTIN, Manchester. Extracting pitch. Dated August 29, 1868.

August 29, 1803.
The patentee mixes with any suitable quantity of boiling water about eighty parts of ceal naphtha, four parts of lime, twelve parts of oil, with four parts of any kind of alkali. The wool is steeped in the mixture for about twelve hours, when the pitch will swim on the surface ready to be taken away for use.—Patent abandoned.

ready to be taken away for use.—Patent abandoned.

2677 W. E. Gedge, Strand. Compressing coal. Dated August 29, 1868.

The patentee describes his invention as follows:—It is based on the principle of pressure, by wedges applied in a rotary manner. It is composed of a framework, supporting the compression pieces, and the mechanism which sets them at work. These compressors are set on the circumference of two circular plates or tables. Each of these plates is provided with openings or cells, in which slide compression pistons are arranged so as to meet each other two and two, in order to grasp the material to be agglomerated or compressed.—Patent abandoned.

agglomerated or compressed.—Patent abandoned.

2678 J. and T. TATTERSALL and T. RICHMOND, Lancaster, Preparing cotton. Dated August 29, 1868.

This relates to apparatus for moving the roller, on which are cards to be ground to or from the periphery of the emery covered grinding roller, and to improved apparatus for regulating and adjusting the necks or bearings of card rollers, when such cards are being ground. At each end frame of the machine, and near the front thereof, a rack is employed, on which is a casting acting as supports to the card roller. These racks are worked by means of pinion wheels, placed on a shaft extending across the front of the machine, and on which shaft is a hand wheel for working the pinions and rucks, so as to cause the card roller to advance on or recede from the grinding roller. A brake is applied to the hand wheel, so as to prevent vibration.—Patent abandoned. Patent abandoned.

Patent abandoned,

2679 E. Jackson and J. Ogden, Oldham. Preparing cotton. Dated August 29, 1868.

This consists in the employment of a balance lever, upon one end of which is formed a trumpet mouth, through which the attenuated and combined slivers pass into the cans after leaving the drawing rollers; the opposite end of the balance lever is supplied with a sliding or adjustable balance weight, that, by its adjustment on such lever, nearer to or farther from its fulcrum, the greatest accuracy can be attained for different weights of cotton passing through.—Patent abandoned. through.-Patent abandoned.

2680 J. M. HUNTER, Strand. Aerial propulsion. Dated

August 29, 1868.
The Lord Chancellor has granted an extension of time for filing the specification of this patent.

2631 E. L. Parairra, Regent's-park. Steam engines.
Dated August 29, 1868.

The patentee introduces compressed airor other gaseous element within the working cylinders of steam engines, and avails himself of the heat of the steam when partially exhausted, to develope the expansive properties of the air or gas, and increase the propulsive force in the rear of the pistons.—Patent abandoned.

2682 W. NAYLOR, Mildmay Park. Raileay brakes
Dated August 29, 1868.
Weighted levers are suspended by a rope or chain passing under or along each carriage of a train, which weights
on being lifted or lowered act by the force of their gravity
through levers and connections upon the brake blocks, thereby forcing them against the periphery of the wheels. -Patent abandoned.

2633 C. F. VARLEY, Beckenham. Telegraphs. Dated August 29, 1868.

The insulated conductor and the strands of the ropes are twisted together in a slow spiral, instead of being placed inside the strands.—Patent completed.

2684 W. S. FLETCHER, Manchester. Door crerice guard

Dated August 31, 1868.

A strip of rubber or other elastic material is held in a clip fixed to the floor, directly under and pressed upon by the door when shut.—Patent completed.

2685 S. NEWTON, Oldham. Swing door hinge. Dated August \$1, 1868.

August 31, 1868.

This consists of a box having a square recess, with a stationary pin in the centre. A spiral spring is placed in this recess; a block rests on the spring, and has at the top a V-shaped groove with rounded tops. The bottom of the door is fitted with a shoe, having a part projecting from the door, of a V-shape, and a hole fitted on the stationary pin in the square recess to act as a bearing.—Patent abandoned.

GREENWOOD, Lancaster. Looms. Dated

August 31, 1868.

This consists in using short pieces of leather strapping so as to embrace and encircle the length of each shuttle box spindle.—Patent completed.

box spindle.—Patent completed.

2687 T. Lerter and W. Trueman, Stafford. Steam engines. Dated August 31, 1863.

This consists, first, in working the slide valves of steam engines. In place of the fixed studs against which the cams or tappets work, the patentees use movable surfaces in the form of anti-friction rollers. It consists, second, in connecting with the condenser two pumps worked by eccentrics on the main shaft of the engine. These pumps are so arranged that while one is making its advance stroke the other is making its are turn stroke. The waste steam and air thus drawn from the condenser pass by pipes connected with the pump cylinders into the atmosphere.—Patent completed.

2688 I. Regulators.

2688 J. FIELDHOUSE, Birmingham. Furnaces. Dated August 31, 1868.

The patentee uses, in addition to the ordinary firegrate in the front end of the internal flue of the boiler, a second firegrate, situated underneath the front end of the boiler;

second firegrate is placed in a chamber or fireplace the second firegrate is placed in a chamber or fireplace made for its reception. On the second firegrate a small fire only is maintained. The smoke and products of combustion from the fuel on the ordinary grate pass along the internal flue to the rear end of the boiler. They then pass back along external side flues to the front end of the boiler, and enter by nearly vertical flues the chamber or fireplace in which the second firegrate is placed. The small fire on the second firegrate, in addition to consuming or partly consuming the smoke from the fuel on the upper or ordinary grate, also heats the bottom of the boiler, and thereby effects such a circulation of the water as prevents the unequal heating of different parts of the boiler.—Patoni completed.

2689 H. WALKER, Warwick. Packing pins. Dated August 31, 1868.

This consists in printing the name and address of the maker upon the raised portions of needle and pin cases, as well as the numbers by which they are known.—Patent completed.

2690 J. WILKINSON, Leeds. Printing carpets. Dated August 31, 1868.

The fabric to be printed is carried forward in an uninter-

The fabric to be printed is carried forward in an uninter-rupted and continuous manner, under a series of printing cylinders or rollers, mounted in suitable bearings in fixed framings, in which are also mounted colour rollers, with the necessary appendages and accessories for the printing rollers, so that when set in motion, the printing operation may be carried on continuously, and without any inter-ruption and intermission, until any desired length of fabric has been printed.—Patent completed.

2691 W. R. LAKE, Chancery-lane. Coupling. Dated August 31, 1868.
This consists in the employment of cushions of india-rubber, in combination with a metal coupling of a ship's standing rigging.—Patent abandoned.

2692 W. R. LAKE, Chancery-lane, Firearms. Dated August 31, 1868.

August 31, 1868.

The rear end of the exterior surface of the projectile is grooved or channelled in such a manner as to form thereon spiral blades or shoulders. From each of these grooves a longitudinal passage or perforation extends to the forward part of the projectile. When the latter is expelled from the gun, air rushes through each of the passages, and, impinging upon the spiral blades or shoulders, gives to the projectile the desired axial rotation. Thus the riling or growing of the gun is rendered entirely unnecessary.—Patent abandoned.

2693 W. E. GEDGE, Strand. Turbine guard. Dated August 31, 1868.

This consists of a metal cylinder provided with blades.

set about 10in, apart, and covered with a grating or wire gauze. The cylinder is placed in front of the turbine, and turns on an axle, set at its two ends in two pieces of wood or metal.—Patent abandoned.

2694 N. THOMPSON, Now York. Culting nippers. Dated August 31, 1868.
The cutting edges of the nippers are forged from pieces of steel, which are dovetailed into the sustaining jaws. These cutting edges are as close as possible to the knuckle or hinge.—Patent abandoned.

or hinge.—Patent abandoned.

2635 L. T. A. P. RIVIERE, Cognac, France. Bottle cases.

Dated August 31, 1863.

The box or case is divided by partitions, having holes in them for the bottoms of the bottles to pass through; the holes in one partition are intermediate to the holes in the next partition; other partitions have holes also fitted in the case for the necks of the bottles.—Patent completed.

2696 J. C. Martin, Barnes. Gelatine. Dated September 1, 1868.

This consists in treating the cartilaginous matter of bone, after leaving the acid solution, in which the earthy matters have been dissolved out, with successive solutions of lime, or lime and caustic soda, weak at the commencement, and of gradually in prescript, are the solutions of the commencement, and of gradually in prescript. of gradually increasing strength, alternating with washings in water, causing a bleaching and softening of the material, rendering it soluble when submitted to heat of a compartively low temperature, and producing a white, strong, and tenacious jelly.—Patent completed.

2697 J. and W. BADGER, York. Steam engine. Dated September 1, 1868.
This consists in an arrangement of governors and ex-

This consists in an arrangement of governors and expansion gear, whereby the nacessity for the use of the ordinary throttle valve is obviated. On the end of a rod of the main shaft is a curved bar, connected at its upperend to a rocking lever, forked to embrace the shank of the governor stem; the governors are carried by horizontal bars, fixed to a crosshead; a valve rod is connected to the curved bar, and its opposite end carries a compound valve, which forms the exhaust and supply valve in one casting.—Patent abandoned.

2608 I Langey London Tripting good Dated September 1988.

2698 J. LADLEY, Leeds. Twisting wool. Dated Septem-

This consists in stopping each bobbin from rotating separately without stopping the machine.—Patent abandoned.

2699 F. HUDSON, Blackfriars-road. Liquid meters, Dated

This relates to an improved diaphragm, consisting of a central disc, surrounded by outer discs attached to leather, so that the diaphragm is allowed to work freely backwards and forwards. By this combination a perfect shape is maintained at each vibration, which perfects the registration of the meter.—Patent abandoned.

2700 W. C. HOLMES, Gracechurch-street. Gas. Dated

2700 W. C. Holmes, Gracechurch-street. Gas. Dated September 1, 1868.
This consists of a washer, scrubber, and condenser, and is formed into three distinct chambers, the lower one litted with trays and adapted as a washer, the upper and inner one, in which may be placed coke, breeze, or other suitable material, fitted with grids or not as a scrubber, while the outer chamber serves as a condenser. Attached to the top is a funnel or vasc-shaped vessel, supplied with water, which constantly trickles down the interior of the upper and inner chamber from a horizontal pipe, having a number of small holes therein, and connected with the vase before mentioned. The water, after percolating the coke, breeze, or other material, and falling to the bottom of this chamber, descends to the lower chamber or washer, where it is intercepted by shallow trays, over which the water falls in succession.—Patent completed.

2701 T. TOMS, Lambeth. Boots. Dated September 1,

2701 T. Tons, Lambeth. Boots. Dated September 1, 186

The boot is made with a front blocked or compressed

into shape, out of one piece of leather; the back part of the boots made out of another piece of leather also com-pressed into shape. The front and back are joined together at the bottom underneath the ancle; a waterproof gusset is secured in the space above the ancle by sewing.—Patent abandoned.

2702 T.G.F. DOLBY, Clapham. Vaires. Dated Sep.

tember 1, 1868. This consists in fitting metallic base plates to indiaruber valves, and forming an inclined or scarf in the rubber, so that one edge shall rest upon the other without passing through.—Patent completed.

2703 E. Jobson, Dundee. Pianofortes. Dated Septem.

ber 1, 1868.

The hammers or strikers of planofortes are covered with relvet or other piled fabric in lieu of leather.—Patent com-

velvet or other piled fabric in lieu of leather.—Patent completed.

2704 W. R. LAKE, Chancery-lane. Looms. Dated September 1, 1863.

This consists, first, in combining with long upright The levers have books or notches upon their opposite deges, which engage with the lifter and depresser mechanism. It also consists in so constructing and arranging harness jacks that they rest directly upon or against the harness jacks that they rest directly upon or against the harness jacks that they rest directly upon or against the harness jacks that they rest directly upon or against the hearin or cylinder, without the intervention of intermediate mechanism. Also in the employment of a yielding lifter mad arranged that it will yield to any undue strain or the pins of the cylinder, caused by their accidental projection too far from the peripheral surface of the cylinder; and lastly, in operating the warp of a fancy loom by means of hooks, one attached to each extremity of the connections from the barness, and seizing either hook by the movement of a bar or bars in other direction to raise and depress the harness, as may be determined by the contour of the pattern chain, and the retiring of the hooks to their normal condition by the return of the evener bar or bars.

Patent completed.

-ratent completed.

2705 W. W. MAOVAY, York. Glass furnaces. Dated September 1, 1868.

The glass furnace is formed after the manner of an The glass furnace is formed after the manner of an ordinary puddling furnace, with a fireplace at one end and a flue leading to the chimney at the other, and with workafue leading to the chimney at the other, and with workafue looked by stoppers while the melting is going on at the sides. This furnace is formed of a substance known as firestone, which may be obtained, among other places, from the Londonderry quarries, Yensher.—Patent and H. A. Bouward and the standard of the stan

2706 H. A. BONNEYILLE, Piccadilly. Regenerating grain.

2706 H. A. BONNEVILLE, Piccadilly. Regenerating grain.
Dated September 2, 1868.
The object of this is, first, to regenerate grain, seed,
betries, floor, fecula, dry vegetables, potatoes, and other
betries, floor, fecula, dry vegetables, potatoes, and other
such like alimentary substances, spoiled by fermentation
or excessive moisture, so as to render them once more it
for food. The substances are placed in apparatus, from
which the atmospheric air has been removed by means of
which the pumps. After submitting them to this treatpresent no difference with those
which have already been in a healthy state, and the flour
notably becomes again fit for conversion into bread.

Patent completed.

2707 J. H. GREENER, Adelphi. Insulating. Dated Sep-

tember 2, 1868.
This consists in the construction of insulators, composed of iron coated with an enamel of a non-conducting character; by preference, that manufactured in accordance racter; by preference to R. A. Brooman (No. 1646), 1863.

—Patent abandoned.

Patent abandoned.

2708 J. Adams and H. Bartlet, Jersey. Bottle stoppers.
Dated September 2, 1868.

The stopper is constructed of a cylinder or plug of hard wood, having a greater specific gravity than water, such as lignum vitee. This cylinder or plug is of a diameter as lignum vitee. This cylinder or plug is of a diameter as lignum vitee. This cylinder or plug is of a diameter slightly less than that of the opening of the neck of the bottle. And of a length exceeding the height of the neck of bottle. Near the lower end of the cylinder and around it is a groove, in which is fixed an india-rubber washer, and the cylinder, at a short distance above this groove, is hollowed out, to allow of space for the washer to be forced into, in order to pass through the neck of the bottle. To apply this stopper, the washer end is inserted in the neck of the bottle, by which the washer is flattened down, until it reaches the part of the bottle below its neck, when the washer expands and recovers its normal position. This stopper closes the bottle when it is filled by the pressure of the gaseous liquid from within, and the bottle is opened by applying pressure on the top of the stopper from without, by which it is forced down, and leavos the mouth of the bottle open.—Patent completed.

month of the bottle open.—Patent completed.

2709 E. CORTAZZI, New Cross. Suspending railways.
Disted September 2. 1868.

This consists of rails so constructed as to prevent vehicles getting off them, the whole being suspended from cables, or attached to suitable scaffolding, framework, or cables, or attached to suitable scaffolding, framework, or pillars, at a convenient distance above the surface of the ground. Two or more lines of rails may be arranged, side the suspended from separate cables, or attached to yold, suspended from separate cables, or attached to one and the same set of scaffolds or supporting frames, in which latter case the distance apart of the vertical in which latter case the distance apart of the vertical pillars or supports of the scaffolding or framing, and the length of the cross arches or bearers must be proportionately increased to allow room for the bodies of the vehicles to pass.—Patent completed.

2710 C. E. BROMAN, Fleet-street. Treating wool. (A communication). Dated September 2, 1868.

The process embraces the following consecutive operations:—First, cleansing or scouring of the raw wool by itons:—First, cleansing or scouring of the raw wool by itons:—First, cleansing or scouring of the raw wool by itons:—First, cleansing or soding and urine, and fuller's means of salts of soda, crystals of soda, urine, and fuller's carth. The bath would be composed of about 1,000 quarts of water, 50lb. of salt of water, 60 quarts of urine quarts of water, 50lb. of salt of water, 60 quarts of urine quarts of water, solb, of salt of water, 60 quarts of their search, and 25lb. to 35lb. of fuller's earth, 13-2deg. strength, and 25lb. to 35lb. of fuller's earth, Second, washing in water, to deprive the wool of the falt of immersion of the wool for about four hours in a bat. of immersion of the wool for about four hours in a bat. of water and sulphuric acid, the strength of the bath beinger when cold. Fourth, drying of the wool at a temperature of about 100 deg. to 125 deg. Fab. Fifth, beating of the wool to cause the desiroyed vegetable part to fall out. Sixth, immersion for from an hour to two hours

with agitation of the wool, in a bath of chalk.—Patent

abandoned.

2711 H. AITKEN, Stirling, North Britain. Treating grain-Dated September 2, 1868.

The patentee forms a core up the centre of the stack to within a few feet of the top. Air, gas, or steam is then forced into the core, until the straw or grain are brought to a dry and sound condition. When heated air, or gas, or hot steam, is used, it will be proper, towards the end of or hot steam, is introduce air of the ordinary temperature, or air cooled down with tee or otherwise, or by forcing air at a high degree of pressure, so as to expand into the stack, and so produce great cold.—Patent abandoned.

2712 J. F.C. CARLE Leadenhall street. Firegram. Dated.

stack, and so produce great cold.—Patent abandoned.

2712 J. F. C. Carle, Leadenhall-street. Firearms. Dated
September 2, 1868.

This consists in a peculiar construction of needle action
breed loaders. The chamber for the cartridge has a
breed loaders. The chamber for the cartridge has a
trumber of projections on it, at certain distances apart.
The sliding bolt has lugs or projection pieces, which take
into slots to hold it safe. The cartridge is composed of
double paper. Compressed paper wads are inserted into
the base, and an aperture is formed in the wad for the
ignition compound.—Patent completed.

2713 J. Evans. Stafford. Welding tubes. Dated Sen-

ignition compound.—Patent completed.

2713 J. Evans, Stafford. Welding tubes. Dated September 2, 1868.

This consists in employing a double set or two rows of dies, arranged opposite to and as counterparts of each other, in slide rests; they are capable of advancing and other in slide rests; they are capable of advancing and receding in a horizontal or vertical direction to or from the centre of the machine, so as to compress or close around, and securely weld the tube, which is drawn in a heated state from the fire through the sets, by welding or gripping tools.—Patent completed.

2714 J.J. Camprill. Reading. Wrappers. Dated September 2, 1865.

gripping tools.—Patent completed.

2714 J. J. CAMPELLI, Reading. Wrappers. Dated September 2, 1868.
This consists of a wrapper of jute, hemp, or other textile matter, made into two or more pieces, specially for securing bales of cotton, jute, and other fibrous material, either in a raw or manufactured state, and is intended to supersed the separate rope lashings or iron bands.—Patent completed.

completed.

2715 T. FORSTER and J. HEARTFIELD, Croydon. Indiarubber sponge. Dated September 2, 1868.
This consists in combining with india-rubber, guttaThis consists in combining with india-rubber, guttathe compounds, ground, animal, or
vegetable fibre together, with water, or other liquid or substance, which will generate vapour in the curing process,
or, in some cases, charcoal or other absorbent material
may be used in place of fibre.—Patent completed.

or, in some cases, charcoal or other absorbent material may be used in place of libro.—Patent completed.

2716 W. C. GREEN, South Molton-street. Firearms.

Dated September 3, 1868.

In the fixed part of the breech a striker is fitted to slide. In the fixed part of the breech a striker is fitted to slide. In the fixed part of the breech a striker is fitted to slide. In the fixed part of the breech a striker is fitted to slide freely to and fro in line with the axis of the barrel in a guide formed on the under side of the tail piece of the guide formed on the under mounted on a fulcrum in the trigger plate, the nose of which hammer projects up through a place, the nose of which hammer projects up through a precess or slot formed in the striker of the said hammer. A lever forming the trigger guard is mounted on a fulcrum in the trigger plate in front of the hammer. The upper in the trigger plate in front of the hammer. The upper on the lower end or trigger guard being lowered, comes into contact with the hammer and moves it back, together with the striker for cocking the gun. The barrel, which with a projecting catch on its under side, received in a with a projecting catch on its under side, received in a breech piece for locking the barrel. The rear end of this breech piece for locking the barrel. The rear end of this but is hook-shaped, and engages with a projection on the upper end of the lever or trigger guard before mentioned, so that on the trigger guard being lowered the bolt will be drawn back and the barrel unlocked for tilting simulation back and the barrel unlocked for tilting simulation with the cocking of the gun.—Patent completed.

2717 J. NEWMAN, Bedford-square. Puzzle fan. Dated

2717 J. NEWMAN, Bedford-square. Puzzle fan. Dated

2717 J. NEWMAN, Bedford-square. Puttle Jan. Dated September 3, 1868.

This relates to those which, when folded, are entirely enclosed in a tube, and are brought out or re-entered by pulling a cord on one side or the other. It consists in making the fan come out and unfold automatically and instantaneously by the aid of two helical springs placed within the tube or tubes.—Patent abandoned.

within the tube or tubes.—Patent abandoned.

2718 F. Preston and R. C. Ross, Manchester. Railway stop blocks. Dated September 3, 1863.

The patentees make use of a rocking block placed between the stop block. This rocking block fits into the between the trails, or the stop block may be arranged so, that, instead of rocking or revolving, it may be moved to alter its or the stop block may be brought in line with the rail or the stop block may be brought in line with the rails, as required. The block may be secured in the rails, as required. The block may be secured in the rails, as required, or the stop block may be moved to and froquired position by a pin or wedge; it is moved to and fround have and connecting rod, or otherwise, and by a hand lever and connecting rod, or otherwise, and by and down in the space between the ends of the rails by means of a lever or handle, or otherwise.—Patent completed.

abandoned.

2720 J. GRIFFITHS, West Firle, Sussex. Uprooting trees.
Dated September 3, 1868.

The patentee proposes to secure a rope or chain to the tree or root to be uprooted. The rope is connected to tree or root to be uprooted. The rope is connected to double or single blocks, through which a tackle is rove, double or single blocks, through which a tackle is rove, secured at one end to an anchor (the stump of a tree for secured at one end to an anchor (the stump of a tree for secured at one end to an anchor (the stump of a tree for secured at one of the tree, acting as a sort of and the roller at the foot of the tree, acting as a sort of fulcrum, materially assists in uprooting it.—Patent completed.

pieted.

2721 A. M. CLARK, Chancery-lane. Camp bedstead. Dated September 3, 1868.

This consists in the combination of a travelling trunk. This consists in the combination of a travelling trunk. The same time to hold or box and bedstead, serving at the same time to hold or box and other articles, and also as a courh camp or travelling bed or litter for the transport of wounded or sick persons.—Patent completed.

2722 E. L. PARKER, Birmingham. Fastenings for braces.

2722 E. L. PARKER, Birmingham. Fastenings for braces. Dated September 3, 1863.

This consists essentially of two metallic plates hinged or jointed together. The under or back plate has two parallel slots in it, through which the end of the brace is passed. The upper or front plate has a series of teeth, when the plate is shut down upon the under or back plate, press the brace against the bar, between the slots or under the back plate, and hold it securely. Near the lower edge of the under or back plate is shut down, posses through a hole in the said upper or front plate is shut down, passes through a hole in the said upper or front plate of the tubes of the brace are secured to a ring or plate of the hook, or when the hole in it, and when the ring is hooked on the hook, or when the hole in the plate of metal is engaged with the head of the stud, the upper or front plate is securely held between them.—Patent completed.

securely held between them.—Patent completed.

2723 T. V. J. ATHERTON, Lancaster. Looms. Dated September 4, 1868.
This consists in an apparatus for holding the brake from the flywheel, when the loom is worked for a short time by hand, and for removing the brake when the loom is started. To the stopping and setting-on handle a short is started. To the stopping and setting-on handle a short is started, having at the pointed end a raisod projecting, and at the other end an inclined part projecting downwards, which part passes through a slot in the side frame of the loom; the long arm of the ordinary brake lever rests on the short arm.—Patent abandoned.

2724 T. GRAFTON. Birmingham. Slicing eucumbers.

lever resis on the short arm.—Patent abandoned.

2724 T. Grafton, Birmingham. Slicing cucumbers.
Dated September 4, 1868.

This consists of a fluted or corrugated hollow cylindrical case, open at both ends, in which case a travelling cal case, open at both ends, in which case a travelling late or holder works, by which the cucumber or other plate or holder works, by which the cucumber or other in one of the flutes of the case, passes through a screw hox on the plate or holder. By turning this screw, motion is given to the travelling plate on the ends of the screw. Outside the ends of the case are knives or cutters, by Guiside the ends of the case are knives or cutters, by giving a rotary motion to which (the cutters) the cucumber or other article fixed in the plate or holder described is advanced from the open end of the case at which the knife or cutter is situated, and cut or sliced by the said knife or cutter.—Patent completed.

2725 J. H. JOHNSON, Lincoln's Inn. Extracting colour.

knife or cutter.—Patent completed.

2725 J. H. Johnson, Lincoln's Inn. Extracting colour.

Dated September 4, 1868.

This consists in the employment of aniline or salts of This consists in the employment of aniline or salts of aniline in conjunction with an oxidizing agent, such as aniline in conjunction with an oxidizing agent, such as chlorate of potash, together with an acid such as hydrochlorate of potash, together with about 20 grammes of warm water, and made into a paste with about 2 pints of warm water, and made into a paste with about 2 pints of warm of potash, to this is added about 40 grammes of sulphate of iron, and about and about 4 grammes of sulphate of iron, and about 10 grammes of muriate of amnionia. To this mixture, when cold, there is to be added about 60 grammes of aniline or of a salt of aniline, and the mixture is then ready for use.—Patent abandoned.

2726 G. White, Cheapside. Precenting incrustations in

ready for use.—Patent abandoned.

2726 G. White. Cheapside. Precenting incrustations in boilers. Dated September 4, 1868.

This consists in the employment of a metal lining fixed over the entire length of a boiler, at a small distance apart, against the lower part of the inner surface. The upper portion of the lining extends at a small distance above the normal level of the water of the boiler. Small holes the normal level of the water of the lining, in each of which holes a corresponding short tube is inserted, whilst layer of fron turnings, pebbles, or other suitable heavy materials is provided in this part of the lining, and serves as a collector for the incrustating matters.—Patent abandoned.

2727 T. BUTTERWORTH, Oldham. Pumps. Dated Sep doned.

tember 4, 1868.

The pump consists of an ordinary barrel and plunger. The pump consists of an ordinary barrel and plunger, but, instead of the ordinary suction and delivery valves, a but, instead of the ordinary suction and delivery valves, a but, instead of the ordinary suction and delivery valves, a but, instead of the plung barrel and suction pine, munication between the pump barrel and suction pine, munication between the pump barrel and delivery pipe. The and between the pump barrel and delivery pipe, one to the pump barrel, is connected to the suction pipe, one to the pump barrel, and one to the delivery pipe, and a passage is cut in the and one to the delivery pipe, and a passage is cut in the pump barrel and the suction pipe and delivery pipe alternately.—Patent completed.

alternately.—Patent completed.

2728 D. Jones, Worcester. Umbrella stand. Dated September 4, 1868.
This consists in the construction of stands for helding This consists in the construction of stands for helding and supported by a tube, which may be of any shape. The tube ported by a tube, which may be of any shape. The tube is placed in an angular position for the purpose of throwing the article supported in a backward direction, so as to be less in the way. The tubes or supports are fitted into a body acting as a reservoir, with outlets for emptying the water, and this body may be of any shape, or it may be made water, and this body may be of any shape, or it may be made to fit or suit any recess or place it may be required to convey stray drops into the reservoir is fitted with perforations to convey stray drops into the reservoir. A rail is attached to the body to keep damp umbrellas or parasols from touching walls or articles placed in proximity thereto.—Patent completed.

2729 A. M. A. LAFORGUE, Paris. Surgical instrument.

2729 A. M. A. LAFORGUE, Paris. Surgical instrument.

Patent completed.

2729 A. M. A. LAFORGUE, Paris. Surgical instrument.
Dated September 4, 1868.

This consists of a haudle made hollow or solid, and having at its upper extremity, a bag made of goldbeater's skin, constructed with two valves, separated by a plane or diaphragm passing through the axis. The two valves are connected by a seam made with two flue wires or threads connected by a seam made with two flue wires or threads joining at the top; both valves are furnished with a strip joining at the top; both valves are furnished with a strip in the suitably fixed to their tops, the lower part of the bag being fixed to the handle; the extremities of the straps and of the wires are attached to another wire or cord passing into the interior of the handle, if it is hollow, or into exterior grooves if it is so id. The bag is filled with medically powder, through an exterior hole made in the handle, and to pass into the required cavity by means of the caused to pass into the required cavity by means of the handle. It is then only necessary to draw a ring or nob at the end of the wire, and the gram threads or wires will solid in the holes made for their passage, and the valves are set free. The straps from the top heing drawn by the wire or thread, will open the bag, folding hack exteriorly will on each side the membrane or other material of which the valves are made, leaving the powder at the part required.

Patent completed.

#### APPLICATIONS FOR LETTERS PATENT.

Dated March 9, 1869.

Dated March 9, 1869.

707 W. R. Lake, Southampton-buildings, Chancery-lane. Improved apparatus for converting a reciprocating motion into a rotary motion.

773 H. C. Bartlett, Garlick-hill, City, and A. G. Southby, Bulford, Wilts. Improvements in paper-making.

774 W. H. Harfield, Royal Exchange-buildings, City. Improvements in capstans and capstan windlasses, chain controllers and stoppers, and in chain shackles.

775 J. B. Palmer, Palace Works, Old Ford-road, Bow. Improvements in the manufacture of matches and fusees, and of surfaces to be used for igniting matches and fusees.

776 H. Delattre, Roubaix, France. A new kind of

tissue.
777 P. B. O'Neill, Rue du Faubourg St. Honore, Paris, and W. H. H. M'Neight, Dublin. Improvements in apparatus or machinery for raising, lowering, and suspending venetian or other blinds and shutters.
778 E. W. and M. Slade, Wilton, near Salisbury. An improved portable oven or cooking apparatus.
779 J. Thomas, Birmingham. Improvements in repeating frearms.

779 J. Thomas, Birmingham. Improvements in repeating firearms.
780 C. Vero, Atherstone, Warwickshire. Improvements in machinery for hardening and felting the bodies of hats and other coverings for the head.
781 J. Thomlinson, Abbey-street, Carlisle, and W. Thomlinson. Loughborough, Leicestershire. Improvements in the manufacture of paper and textile fabrics, and in the preparation of gypsum to be used in such and other manufactures.
782 W. T. Carpenter, West Minster, Isle of Sheppy, Kent. Improvements in apparatus used in the manufacture of gas.
783 W. R. Lake, Southampton-buildings, Chancerylane. Improvements in breech-loading firearms.
784 J. Tenwick, Grantham, Lincolnshire. Improvements in the construction of annealing ovens and kilns.

LONDON: THURSDAY, MARCH 25, 1869.

# TEMPORARY STRUCTURES.

"OH, it is only temporary." This is the ordinary answer given to anyone who ordinary answer given to anyone who hazards a remark respecting the safety of a scaffolding, dam, bridge, or other work of construction doing duty until its permanent successor is erected. In many instances, it would appear that anything that will just hold together is considered adequate for hold together is considered adequate temporary purposes; and the limbs and lives temporary purposes; and the limbs and lives of those who have to trust to them for support are jeopardized with the most reckless indifference. It was but yesterday, that a temporary bridge, nearly 60ft. above the road beneath, fell in, burying everything and everybody in its fall, and involving a serious loss of life. Sometimes the public suffer from the insecurity and the unsoundness suffer from the insecurity and the unsoundness of work of this nature, but more frequently the workmen. At the same time, it is not to be imagined that every accident that may happen to a workman is due to causes of a constructive character. Frequently, they themselves, and themselves only, are to blame for what befals them. Impunity from danger begets rashness, and the manner in which some of them will hazard their personal safety is deserving of the strictest condemnation. Not only does it betray on their part a total disregard for their own lives, but by the irresistible influence of bedayample. but, by the irresistible influence of bad example, it induces others who are neither so skilful nor it induces others who are neither so skillul nor gifted with the same nerve, to imperil themselves in a similar manner, frequently to their own destruction. This self jeopardizing of human life on the part of workmen should be strictly forbidden by those in charge of works, under pain of instant dismissal. Independently of the humane view of the question, it is a stroke of policy besides. of the question, it is a stroke of policy besides, since masters and employers have often to make compensation for accidents of this nature, which result solely from the rashness and improved one of the sufferent themselves. and imprudence of the sufferers themselves.

It would perhaps, in some instances, be difficult to assert whether the greater negligence and indifference were displayed by those who erected temporary structures. or by those who daily and hourly risked their safety upon them.

one of the most important temporary terretures that has ever been erected, in whether its magnitude be regarded, or the length of time it has done duty, is Blackfriars Bridge; but in this, as in all similar instances, there is very little doubt of its security. Before any accommodation work can be placed at the disposal of the public, it is carefully examined and tested, and, if approved, certified by the proper authorities as fit for its intended purpose. The lives of the public are thus protected, in a great measure, from those contingencies which are attendant upon those descriptions of structures erected simply for the use of the operatives and labourers. We say, "protected in a great measure," because although a preliminary testing of any temporary One of the most important temporary a preliminary testing of any temporary public work is a wise precaution and a comparative safeguard against accidents, yet it is nothing more. Serious catastrophes have happened on lines of railways the day after they have been passed by the inspecting officer, and his examination, which embraces the permanent way, the work of construction, and the arrangement of the stations and signals, is conducted with great care, and a minute inquiry into the whole of the working and constructive details. That there has

erecting many examples of temporary construction will be apparent to anyone who regards the different principles upon which the commonest instance of all, namely, scaffolding, is at present put up. As a case in point, we might refer to that surrounding the partially built new hospital upon the south bank of the Thames at Westminster. It is impossible but to observe that there is a scientific distribution and arrangement of cross braces, struts, ties, and stretchers, to which, some years ago, builders and contractors were entire strangers. There are two chief reasons for these improvements and reasons for these improvements and departure from the old rule of thumb method. One undoubtedly is that builders and contractors, from the greatest to the least, have progressed in accordance with the spirit of the times. The other, that the introduction of heavy travelling gantries, steam cranes, and other powerful mechanical aids and appliances, has necessitated a more substantial and accomplished released a constitution. It would be and scientific plan of erection. It would be impossible to build houses similar to those now in process of construction upon the Marquis of Westminster's estate, with scaffolding designed after the ancient poles and putlog fashion.

While sometimes temporary works fail from sheer ignorance or parsimony on the part from sheer ignorance or parsimony on the part of those constructing them, at others they are the result of misfortune rather than of culpability. A notable instance of this description occurred some time ago, in the "blow" that took place in the dam erected to carry on the formation of the Thames Embankment from the Temple to the new Blackfriars Bridge. This dam was built in a manner nearly precisely similar to that under the protection of which the wall upon the south side of the river, from Stangate to the south side of the river, from Stangate to Lambeth, was so rapidly and so successfully constructed. If we do not mistake, the very same foreman of works was employed upon both jobs. In the former, there was no accident of any kind; in the latter, the dam failed, entailing considerable delay and loss upon the contractor. How is this to be accounted for? Were the conditions in accounted for? Were the conditions in the two cases similar, or only apparently so? The fact is, that the holding ground for the piles on the south or Surrey side of the river is much better than that upon the Middlesex share and apparently the depths to which shore, and consequently the depths to which they must be driven respectively to attain the same holding power is not constant, but varies considerably. The dam that failed between the Temple and Blackfriars would no doubt have held its own upon the opposite The same results were proved to obtain with respect to the nature of the foundations in the bed of the Thames, in getting in the piers for the new Blackfriars Bridge. and in one instance an extra depth of over 30ft. had to be sunk to, in order to find firm ground. Whatever negligence might be displayed in temporary works of lesser magnitude and importance, there is no lesser magnitude and importance, there is no contractor so blind to his own interest as to knowingly build his dam too slight, or even to risk the chance of a "blow" during the to risk the chance of a blow during the progress of the permanent erection. If a large dam were to fail en masse, unless the contractor were a man of considerable capital, it would almost be tantamount to a temperature of the works, since the loss would stoppage of the works, since the loss would be enormous, all of which would fall upon himself. Without intending for a moment to depart from the principles of strength and stability, there is nevertheless frequently a disposition to cut the scantlings down too fine, and endeavour to save labour and material in defiance of the consequences that may ultimately attend conduct so injudicious. It is, in the long run, never worth while to risk the chance of an accident for the sake the permanent way, the work of construction, and the arrangement of the stations and signals, is conducted with great care, and a minute inquiry into the whole of the working and constructive details. That there has been a great improvement in the method of

temporary works should be strong and sound enough to last the time they are intended; but it is also just as much to his interest that they should cost as little as possible, and, as these are rather conflicting, it is not to be wondered at that sometimes it is not to be wondered at that sometimes a mistake is made in their reconciliation which is not discovered until it is too late.

# AMERICAN ORDNANCE.

T may be within the recollection of our readers that a joint committee of the United States Congress was some time since appointed to enquire into and report upon the question of ordnance. Their object was to determine the value of the various systems of construction at present in use, as well as to investigate the practice adopted in procuring guns and stores for the Ordnance Department. The committee made their Department. The committee made their report on the 15th of February last, and the material portion of it comes to us through the American "Army and Navy Journal." The committee first review the various systems of ordnance adopted by European powers, and arrive at the conclusion that none of these systems have proved successful in preventing the bursting of guns, or in giving them uniformly reliable and years. in giving them uniformly reliable endurance.
The committee do not think it necessary to discuss further the various European systems of gun-making. None of them, say they, have shown exemption from the rule of failure, and experiments with them on the part of thier Government would be of doubtful value. In other words, the Americans are much obliged to us and other powers for the many thousands we and they have expended upon the question, and are so satisfied with the results that they do not desire to experimentalize in a similar direction. Their farfamed Rodman system of cast-iron guns proves to be no more satisfactory to them than other methods of construction, now than other methods of construction, now that they have resolved carefully, dispassionately and disinterestedly to investigate the whole matter. The Rodman system, say they, has had the merit of cheapness, and, when applied to smooth here gives had had when applied to smooth-bore guns, has had claimed for it superiority over European systems; but it must be considered to be equally tems; but it must be considered to be equally a failure with the others, especially when applied to rifled guns. The Chief of Ordnance of the Navy, in his last report, acknowledges this to be the case. He says:—"Opinions differ quite as widely in regard to the preferable mode of developing ordnance power, whether it shall be by smooth or rifled to the preferable mode of developing ordnance power, whether it shall be by smooth or rifled bores, by loading at breech or muzzle, made from iron, cast or wrought, or from steel, solid or in connected parts. The relation of mass to velocity is also unsettled. In fact, the question involves the necessity of going back to fundamental principles, and starting back to fundamental principles, and starting thence, by well-conducted experiments."

It appears then, that, notwithstanding a series of elaborate experiments, extending over a long period of years, and the practical experience of the recent war, the ordnance officers of the American Government have not yet determined upon even the funda-mental principles of their art, and possess no positive knowledge of the problem they have so long sought to solve. Each system of guns introduced into the American service has been subjected to proof tests which were supposed to demonstrate beyond question its supposed to demonstrate beyond question its ability to perform the work required of it. But what are the facts of the case as they stand revealed by practice? We turn to General Gilmore's able report upon the artillery operations of the war, and there we find that at Morris Island twenty-two large guns was the greatest number mounted at one

bombardment, forty-five men were killed and wounded, whilst only eleven are reported to have been killed and wounded by the enemy's missiles during the attack. The battle of Fort Fisher was the only occasion during the war on which rified guns of large calibre were fired rapidly and continuously for any length of time.

The reason why the weakness of these guns was not discovered before they were supplied for service, can only be referred to a defective system of proving them. The so-called proof was comparatively valueless, and was in no way a guarantee that the gun would perform in active use what was expected of it. Here, then, is clearly a defect in the organization of the Ordnance Department, which calls for a remedy. The causes which underlie and contribute to these results appear to be twofold. In the first place, the post of ordnance officers is secured to them for life, and, as a natural consequence, they have not, as a rule, that incentive to exertion and improvement which stimulates men under other conditions. Moreover, they have become attached to routine and the traditions of their corps, are jealous of innovation and new ideas, and slow to adopt improvements. As an illustration of this, we may mention the fact that the late war was fought with muzzle-loading rifleswith the exception of the cavalry carbines, which, we believe, were chiefly of the Spencer repeating pattern—although a variety of good breech-loaders were constantly urged upon the Government. In the next place, ordnance officers, are educated to a speci-alty, and consider themselves possessed of a perfect knowledge of their subject. They therefore regard private inventors and mechanics who offer improvements in arms as pretentious innovators who have no as pretentious innovation. They discourage rather than encourage the inventive talent of the country, which, from their position, they are enabled to repress, or more probably to another channel. Many complaints of improper and oppressive treatment have been laid before the committee by persons who have sought to draw the atten-tion of the proper authorities to what were supposed to be vital principles connected with their art.

The progressive development of the science of ordnance in America has been further and seriously retarded by the circumstance that prominent officers have been inventors of arms, and have possessed sufficient influence to secure the adoption and retention in service of their inventions, frequently without due regard to the question of real merit, and to the preju-dice of other and better devices brought forward by private inventors, or brought out in other countries. Then there is a still further difficulty which calls for a remedy, and that is, there are two Bureaus of Ordnance-the army and the navy—and there is a decided want of co-operation between them. Great diversity exists in the practice of the two branches of the service, respecting the arms adopted, and the manner of proving, mounting, and using the same. The calibres, models, chambers, and ammunition of the navy guns are entirely unlike those in use in the army. For example, the navy 12-pounder boat howitzer has a calibre of 3.4in., while the army 12-pounder guns are of the calibres of 3, 3.2in., 3.67in., and 3.8in. The chamber of the navy gun is of parabolic form, while the army gun has either a cycloidal chamber or none at all. The models of the The models of the two guns are none at all. entirely different, so that neither could be used on the carriage of the other, the army guns being furnished with trunnions, and the navy gun having, in some cases, the loop and loop-bolt of the old carronade. The system of sighting is also different, so that a gunner in one arm of the service, without special instruction, could not use a gun belonging to the other, one being graduated to seconds of time of the flight of the shot, and the other to degrees of elevation. The navy has 8, 9, 11,

and 13-inch smooth-bores, while the army guns are of the calibres of 6,8,10, and 12-inch, In the guns of the two branches of the service. there is no uniformity in either rifle or smooth-bore, in the twenty calibres adopted below the calibre of the 32-pounders. It is impossible to use navy ammunition in an army gun, or army ammunition in a navy gun. that, on all points, we find that co-operation between the army and navy while in active service is materially restricted, if not entirely prevented, on some of the most essential points. No advantages are claimed for this want of uniformity, whilst the disadvantages are numerous and patent to all. This has all arisen from the circumstance that officers in the two branches of the service have succeeded in securing the adoption of their own inventions. Hence, a rivalry has arisen between them, which has prevented fair com-petitive trials of the various devices and systems advocated by each, neither being willing to admit the merit of the other's inventions, nor to utilize the knowledge gained either by their successes or their failures. The experiments, being duplicated on account of this jealousy, have been, necessarily, needlessly expensive. A further increased expense results, in time of war, from maintaining two separate organizations for the procurement of The two ordnance departments are brought into competition with each other, in the matter of contracts and purchases of war material from the public work-shops and factories of the country, thus putting the Government in the attitude of bidding against itself. The upshot of all this is that whilst such a state of things is allowed to continue, no progress towards obtaining better guns is likely to be made. The committee, therefore, deem the best method of securing such impartially conducted experiments as will determine with certainty what are the best arms, and to insure greater economy and regard for the public interests in their purchase and adoption, is the formation of a mixed ordnance commission, composed of officers of high character, detailed from both the army and the navy, who shall have no interest in patents or devices for arms. The investigations of the committee lead them to the following conclusions:-

1. That no more heavy guns should be purchased for mounting in the fortifications or use on ship-board, until such improvements are made in the methods of fabrication as will insure more reliable endurance than has heretofore been exhibited.

2. That the Rodman system of gun-making, while partially successful in smooth-bores and small calibres, has so far failed in rifles of large calibre as to show it to be unworthy of further confidence. Recent improvements in defensive works and armourplating, render heavy rifled guns the most efficient means of attack, and no system of fabrication which does not furnish such guns should be adopted or continued. The principle of initial tension, which is the basis of the Rodman system, appears to be of doubtful utility, as applied by General Rodman, especially forrifled guns. This tension, it is admitted, gradually disappears from the gun with age, and in time is entirely lost.

3. That guns cast solid, in the manner practised in the navy under the direction of Rear-Admiral

3. That guns cast solid, in the manner practised in the navy under the direction of Rear-Admiral Dahlgren, while exhibiting satisfactory endurance as smooth-boros with small charges and hollow projectiles, have not the requisite strength for rifles of large calibre. This mode of casting seems to be defective in principle, as the tension inaugurated in cooling have a tendency to aid the powder to rupture the gun.

4. That experiments should be at once conducted for the purpose ascertaining the real cause of the bursting of heavy guns, and of determining upon some method of fabrication that will secure uniform endurance.

endurance.

5. That every encouragement should be given to inventors, and a full and fair trial accorded to all devices offered to the Government that promise a solution of the orderne problem.

devices offered to the Government that promise a solution of the ordnance problem.

6. That more efficient means for harbour defence should be adopted. The late war demonstrated that sand was the best material for defensive works, and that forts of masonry, such as we have now mainly to rely upon for the protection of our seaboard cities, are insufficient to prevent the passage of armoured or even wooden vossels. The destruction of such defence is only a question of time to ordinary guns of heavy calibre. It was also demontrated that forts alone, of whatever character, cannot resist the

entrance to harbours of powerfully armed ships, if the preponderance of guns on the assailing fleet is sufficient. In the opinion of the committee, obstructions must be largely relied upon for harbour defence, in connection with properly constructed fortifications.

7. That no officer of the army or navy should be allowed to receive a patent for any article required, or likely to be required, for use in those branches of the public service, or be in any way interested in the manufacture or procurement of such articles. It should be the duty of Congress to recognize by suitable rewards, the services of such officers as might make inventions of especial value to the Government.

ment.

8. That the Ordnance Department of the army can be entirely abolished with great advantage as to economy, and without detriment to the good of the service. The duties now performed by officers of that corps, could be performed by officers detailed from the artillery service, under the direction of a chief, stationed at Washington. In this manner, the whole expense of the Ordnance establishment would be saved, and artillery officers, who have not only scientific training but practical experience, would have a voice in the selection of the guns and ammunition they are required to use.

For the reasons we have given, the committee are of opinion that the interests of the public service demand a change in the system of procuring ordnance and ordnance stores, and the manner of conducting experiments, with a view to determining the value of the same. The present system has failed to answer the purpose for which it was designed, and the United States is in the position to-day of a nation having a vast coast-line to defend, and a large navy, without a single rifled gun of large calibre, and a corps of ordnance officers who have thus far failed to discover a remedy for the failure of the guns, or to master the rudiments of science in which they have been tried at the public expense. importance of an immediate change is shown by the fact that the Chief of Ordnance of the army asks for appropriations to purchase over 1,900 guns to arm the forts, not of a new and better system, to be decided upon after more thorough and careful experiment, but of a kind that experience has shown to be inferior in range and penetration to the guns of foreign powers, and unreliable as to endurance. It is proposed that fifteen of these guns shall be smooth-bores of 20in. calibre, 190 of 15in. calibre, and 600 of 13in. calibre.
The experience of all nations goes to prove that the most effective way of developing ordnance power is by rifled guns. To return to smooth-bores, throwing huge spherical masses of iron with low velocities, is to disregard all modern progress in the science of gunnery, and to return to the arms in use two centuries ago. Furthermore, the advisability of using guns of such great size is very doubtful, for the slowness with which they can be handled and fired makes them less effective than smaller guns delivering a more rapid fire. Two hundred of the guns required it is proposed shall be Rodman 12-inch rifles, notwithstanding all of that class of guns heretofore procured for the army or navy, and subjected to test, have either burst disastrously before the lowest reason-able test has been completed, or have given such indications of failing, after a few rounds, as to be considered unsafe. It is proposed also to purchase 610 10-inch Rodman rifles, although the committee cannot learn that any gun of this class has ever been subjected to test in this country, except the Parrot rifles of that calibre, which are acknowledged failures, having been condemned by both branches of the service. From the foregoing it is evident that we shall hear no more of the vaunted excellence of the smooth-bore system, with its heavy shot and charges; whilst a wholesome change appears on the eve of taking place in the administrative department of American ordnance. The committee have done good service to their country in drawing attention to the evils which beset the whole system of management,

volutionizing, not only the naval and military armament of America, but the character of its seaboard defences. ()fficial jobbery will—as far as official inventorship is concerned—cease, and a healty stimulus will be given to private invention—that is, if the Government will only treat inventors fairly and honourably, which in their present benighted condition it is worth their while to do.

#### THE ROYAL INSTITUTION.

AST week, on Tuesday afternoon, the Rev. F. W. Farrar, F.R.S., of Harrow School, closed his series of four lectures upon "Philology." On this occasion, he spoke of languages other than those belonging to the Aryan and Semitic families. Outside these two great families, there are a multitude of languages, most of them, to all appearance, isolated from each other, standing out like mountain peaks above the clouds and mists of antiquity. Most of these languages, especially those of savages, are barren of words, and too rude and uncouth to be at all fitted for the progressive tendencies of higher and more scientific races. Mr. Farrar, in speaking of the paucity of words in the languages spoken by most African savages, said that a great prelate told him that in the work of translating the Bible into one of these languages, the workers were constantly troubled by the lack of words capable of expressing the original meaning. The word "love" among others gave great trouble, and at last they obtained from the natives a word which all parties considered suitable, and it was inserted in the published version. Some time afterwards it was discovered that the word so chosen conveyed the idea to the natives of "meat in an advanced state of putrefaction." Mr. Farrar spoke at some length about the language of the Chinese, also of the Basque language, which, strange to say, has no Aryan roots, and is somewhat allied in structure to the languages spoken by the aboriginal inhabitants of America.

On Thursday, Dr. H. Power lectured again upon "The Eye." He said that all vertebrated animals are distinguished by the possession of only two eyes; the only known exception to this rule being in the instance of a fish found in the Mediterranean, which has about 1,000 undeveloped eyes arranged under its belly. In the course of the lecture he gave a minute description of the construction of the eyes of owls. The owl can enlarge and contract the pupils of its eyes at will, but the human being cannot.

On Friday evening, Dr. Crum Brown lectured at the Royal Institution upon "Chemical Constitution, and its Relation to Physical and Physiological Properties." Admiral Codrington presided. The lecturer dwelt for the most part upon one of the most obscure branches of molecular physics, namely, the probable changes of relation between the hypothetical atoms of compound bodies, when two such bodies enter into chemical union with one another. In the course of his lecture, he said that it is very difficult to estimate the relative volatibilities of chemical substances, because under varying conditions of. pressure, the relative volatility often changes. Thus, under very great pressures, benzole boils at a higher temperature than water.

On Saturday, Dr. William Odling, F.R.S., closed his series of ten lectures upon "Hydrogen and its Analogues." In this lecture he spoke principally of the properties of lithium, sodium, potassium, rubidium, cœsium, and silver as analogues of hydrogen. At first, he said, it might be thought that these substances have little in common with hydrogen, but it must be remembered, that recent researches have gone far to prove that hydrogen is a metal, with a boiling point very greatly below the temperature of the air. The six other metals just mentioned have the properties of uniting

with chlorine, bromine, and iodine, in exactly the same manner as hydrogen; in fact, hydro-chloric acid is chloride of hydrogen. Marsh gas, and substances of the paraffin series, possess many properties which are characteristic of hydrogen, so that in one sense, these compounds are analogues of hydrogen. Dr. Odling, among other experiments, exhibited the combustion of the very rare metal lithium, which burns with a steel-white flame, but when the oxide left after combustion, is ignited in the flame of a Bunsen's burner, it imparts a magnificent red colour to the flame. Potassium gives a slightly violet tinge to the light, which colour is easily masked by the traces of sodium liable to be present upon the mouth of the tube of the burner, or upon other objects which come into contact with the flame. The lecturer accordingly surrounded the flame with a double glass cylinder, the space between the two surfaces being fitted with a weak blue solution of indigo This cut off all the yellow rays, but transmitted the others. The characteristic colours of the lithium and potassium flames could then be seen, even when the light was strongly coloured by the presence of sodium. Dr. Odling closed by noticing the tendency of modern research to merge all the sciences into one, namely, into the "Science of Energetics."

The Royal Institution is closed during Easter, and the lectures will recommence on April 6. The session ends early in June.

# ALBINI'S SELF-REGISTERING COMPASS.

THE advantages of self-recording instruments are so great, and so well understood, that it is hardly necessary to say a word in their recommendation. By some, as in meteorological and astronomical instruments, the sources of error from human observations are altogether avoided, and an accuracy attained which no amount of attention on the part of the observer could possibly secure; while others act as checks upon carelessness and inattention, and, like the tables of the Recording Angel, display in indisputable characters the sins or virtues of a human and responsible agent.

In no case could such an instrument be of greater practical value than in furnishing a record of the course of a ship at sea. So much has this been felt, that many experienced officers, in our own and foreign services, have set themselves to devise an instrument for effecting the object in view. But as perfection is seldom or ever arrived at per saltum, it is no reflection upon those experimenters to say that their attempts in this direction have been only partially successful. It is unnecessary here to describe and to discuss the relative merits of the various means which have been adopted by the several officers who have occupied themselves with the subject, since the instrument we shortly describe and illustrate to-day is confessedly superior to any yet devised, and, indeed, seems to fulfil every possible requirement. A minute description of the various parts shown in the accompanying figures would occupy more space than we can possibly devote, so we content ourselves with indicating the principal parts, and leaving our mechanical readers to fill up the outline we trace by the aid of the drawings.

Figs. 1 and 2 show respectively the front and back elevations of a compass fitted with the self-registering apparatus, which has been invented by Captain Albini, of the Royal Italian Navy. Under the compass card, fig. 3, which is made somewhat larger than usual, is fixed a metallic ring, which is divided on its under side into the same number of points as those on the compass card. The ring is cast in a type mould, and each division is lettered to correspond with the direction of the compass card, which, fitted with the ring, is suspended in why.

the usual way upon a central pointed sup-This central support is fixed upon a port. metallic ring containing a clockwork arrangement. On the face of one of the frame plates (fig. 2) is a clock-dial to indicate the time, and on the opposite frame plate is a piston or rod (shown in fig. 1), which is geared to the clockwork, and made to rise and fall at fixed intervals. The upper part of the piston or sliding rod is made to project over the metallic ring before described. A little below the ring of the compass card when suspended, and at the back of the sliding rod, is a small horizontal elastic cushion. On each side of the elastic cushion, a pulley or drum is fixed, on one of which narrow slips of paper are coiled, while the other receives them as they are uncoiled from the first mentioned, by the action of the clockwork. Above the strip of paper, and in the same line, is a ribbon prepared with an indelible ink. These several parts may be somewhat varied at pleasure. Instead of casting letters upon the metallic ring, any conventional signs may be engraved; and in place of ink, chemical means may be used to leave an impression upon the paper. There can be no doubt, however, that plain lettering, corresponding to the points on the card, is infinitely preferable to any system of conventional signs.

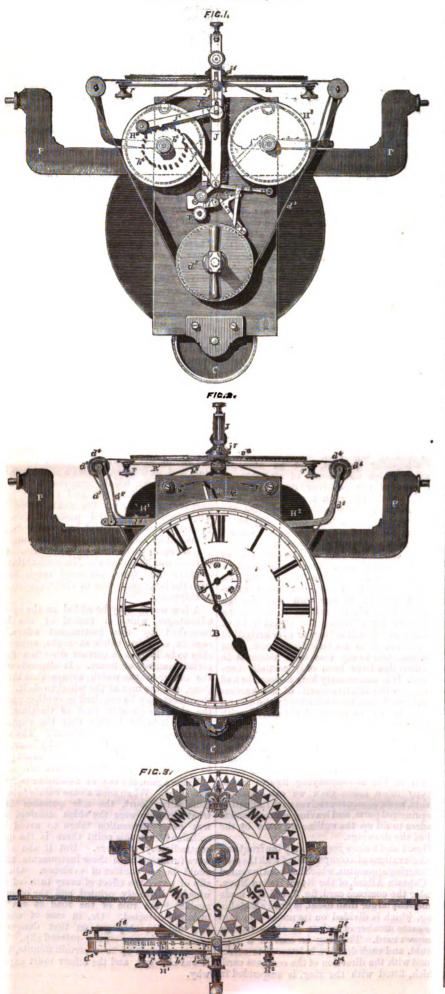

The action of the several parts of the machine is as follows :- At every minute or other fixed interval that may be arranged for, the clockwork causes the quick descent of the sliding rod, the projecting part of which pulls down the metallic ring of the compass card, and causes the types underneath it, in the direction of the ship's head, to press the prepared ribbon and paper slip upon the cushion. Thus the letters on the under side of the ring are printed upon the paper slip, and as the sliding rod is constantly pointing in the direction of the ship's head, the impression made corresponds to the course followed by the ship. After the paper slip has been impressed, the sliding rod rises slowly to its former position, and, as it rises, causes a slight rotation of the pulleys, which removes the printed part of the slip of paper, and brings a blank part into position for the next impression. These are the essential parts of this in-genious instrument, which has been seen and approved by most of our eminent marine engineers and experienced navy officers. of them was shown at the Marine Exhibition, at Havre, and there attracted much notice from the large concourse of visitors interested in shipping.

A few words may be added on the special advantages which a record of the kind furnished by this instrument offers. A captain, on going below at night, orders the ship to be kept in a certain direction for a certain number of hours. It depends upon the officer of the watch to see that this is done, and the men at the wheel to do it. But the officer may be required in another part of the ship the greater part of the time, and how is it to be known that the captain's directions have been carried out? The strip of paper shows it. Here, hour by hour, and minute by minute, is recorded the exact point to which the ship's head was directed.

Take, again, the case of a collision between two ships. When such a case comes into the Admiralty Court, the sole question is in what direction were the ships steering, and was every precaution taken to avoid the collision? On this point there is the usual contradictory evidence. But if the ships were furnished with these instruments, there could be no conflict of evidence. On the slip of paper the effect of every turn of the wheel is distinctly printed, and the offender against "the rule of the road at sea" is instantly detected. Or, in case of wreck, how did the ship get on that dangerous coast? It is seen on the printed slip. The course was safe up to a certain minute, then it was changed, and the officer must explain why.

# SELF-REGISTERING COMPASS. BY CAPTAIN ALBINI, R.I.N.

Lastly, the permanent interest of the record is great. By the aid of these slips of paper, and the captain's observations, and provided with a chart, an owner may trace day by day and mile by mile the exact course of his ship throughout its entire voyage, and thus obtain information which the most carefully kept log-book would probably fail to furnish. We have only to add that the instrument here figured and described can be seen at Messrs. Elliott's, 449, Strand.

# THE INSTITUTION OF NAVAL ARCHITECTS.

THE ordinary annual meetings of this Institution were held on the last three days of last week, in the hall of the Society of Arts, in the Adelphi. The President of the Institution, Sir John Pakington, Bart., took the chair on Thursday morning at the first of the meetings. The proceedings were commenced with the reading of the annual report of the council by the hon. secretary, Mr. Merrifield. The chief points of interest in the report may be summed up in a few words. In the April of last year the Ministry allowed a grant of £250 to the Institution, in recognition of its great use and benefit to the nation, and especially to the shipping interest. A like grant has been allowed for the current year by the present Government. The course of study at the Royal School of Naval Architecture and Marine Engineering at South Kensington, which, from the foundation of the school in the summer of 1860, has consisted of three winter sessions of six months each (November to April inclusive) has been extended to four sessions of seven months each, the sessions to commence in October. The report concluded with a proposal to extend the full membership of the Institution to marine engineers, who heretofore have only been admitted as associates.

After some further formal business, the

President delivered his address. He stated that year by year he became more impressed with the importance of the Institution and of its fitness for the purposes for which it was intended. He congratulated the members on the prosperous financial condition of the Institution, and expressed his conviction that the fact of the grant of £250 having been made by two successive Governments for two made by two successive Governments for two successive years, was a guarantee that the grant would last as long as its requirement. After touching upon the different points mentioned in the report, the President lamented the comparative meagreness of the list of papers to be read at these meetings. Although many of the papers were of great interest and importance, there were others of no less importance, which were conspicuous only by their absence from the programme. He suggested that the council, before the He suggested that the council, before the next annual meeting, should take some steps towards procuring papers on all the subjects of highest interest to the naval architect, so that no subject of importance should not receive its proper share of attention. We think this suggestion of the President worthy of all consideration. It is a great pity that so many persons, to whom time is of great value, should be called together to deliberate upon what is in danger of being merely a fortuitous concurrence of atoms. What disgust must inevitably follow when men of ability arranges to describe the control of the co ability arrange to devote a morning, or, we might say, a day, to the meeting of an in-stitution like this, and find their pains rewarded by the opportunity of being spectators at the trotting out of the hobbies of incipient or disappointed patentees. How much better to ensure papers by able men, on really important subjects—subjects as far as possible removed from the Patent Office, subjects on which the individual knowledge subjects on which the individual knowledge and experience so published may be likely to be of true and lasting benefit to the profession, and the world at large. After this general regret at the absence of important

subjects, the President turned to one particular source of disappointment. "Within the last few days we had had from the highest possible quarters, novelties in the construction of powerful ships suggested, which might profitably form a subject of consideration by such a competent body of gentlemen as the members of this Institution." This reference was to the armour-clad vessels just proposed by the Government, which are to be of 4,400 tons, to draw 26ft. of water, to carry 1,700 tons of coal, to have no masts, and no rigging. It would be imprudent to condemn these novelties merely as novelties, yet the first impression in Parliament was one of doubt. There were important questions in-volved. Could a ship be safe under all circumstances without masts? and would not the expense of the coal required by these ships to enable them to keep the sea be enormous? The President thought it his duty to advert to this proposal, so novel and extraordinary in its character, and he expressed his fear that no paper on the programme would fairly open this subject for discussion. He thought it desirable that the able scientific men who met at these meetings should be in a position to turn their attention to these novel proposals of the Government.

Mr. Charles Lampert, in seconding the report, the adoption of which had been moved by the President, regretted that this Institution did not make some move as a body to advance their knowledge. He suggested the co-operation of the council in recommending to Government the necessity of instituting a series of experiments on the strength of masts, and also on the resistance of fluids to solid bodies moving through them.

In our next, we will proceed to give a resume of the several papers which were read at these meetings.

NOTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

THE PARIS EXPLOSION.

THE awful accident, which spread dismay and consternation among the inhabitants of Paris, near the Sorbonne, has called public attention to an explosive agent very little known. Of the millions who read the newspaper account of the explosion, very few had ever heard or read of picrate of potash; and to many, to whom the name was more or less familiar, it was a novelty to hear of it as an explosive agent. Under these circumstances, a few words respecting it may have an interest for our readers. Picric acid is really a body of the same constitution as gun-cotton and nitroglycerine, and its explosiveness might almost be inferred from its nature. It is directly prepared by treating carbolic acid with strong nitric acid, and, just as happens, when cotton and glycorine are treated with the same acid, three atoms of hydrogen are removed, and replaced by three atoms of nitrous acid. The picric or trinitro-phenylic acid thus obtained is a yellow substance, with an extremely bitter taste. It is largely used in dyeing, and sometimes, it is said, employed in bitter ales, but it is poisonous in moderate doses. When heated, it explodes, if confined, or deflagrates, with some violence, when exposed. It combines with almost all fixed bases, and forms salts, which are mostly of a yellow colour. All of these are more or less explosive, and most detonate sharply, when struck with a hammer. Picrate of potash is not the most explosive of these compounds, and it requires a tolerably hard blow on a firm anvil to make it explode. We are, therefore, disposed to reject that account of the accident which states that the cause of the explosion was a bag of the picrate thrown upon the floor of the warehouse.

M. Fontaine has been recently decorated by the Emperor of the French for the invention of a explosive agent to be used in torpedoes. But this agent, we believe, is not merely picrate of potash, which alone would have very little Telegraph Service.

advantage over ordinary gunpowder. The compound actually used is, we have reason to believe, a mixture of picrate of potash and chlorate of potash, a highly explosive and dangerous com-pound. Such a mixture is easily ignited, and detonates with extreme violence when only lightly struck. Private accounts which reach us when only leave no doubt that at the moment the accident happened the employés in the warehouse were engaged in sifting some materials together-the chlorate and picrate, as we conjecture—but still the immediate cause of the explosion remains a mystery. Anyone, however, who will make an experiment with a grain or two of the mixture we mention, will see that the ignition of a hundredweight of the compound would have tremendous results. At the same time, it must be stated that the explosion of an equal weight of nitro-glycerine would have produced about six or ten times the destructive effects, and the same weight of compressed gun-cotton, fired by a detonating fuse, would have been even more disastrous. M. Fontaine's compound, indeed, while dangerous to handle, is far inferior in destructive force to the no more dangerous nitro-glycerine. and also to gun-cotton, which is perfectly safe to stow and handle.

#### ELECTRICITY AND TELEGRAPHY.

WITH a view to the improvement of telegraphic communication in Turkey, in connection with through Indo-European messages, it is understood that the Turkish Administration are about to proceed immediately with the construction of a new direct line, to be used exclusively for Indo-European telegraph messages. This line will be from Nissa, through Servia, to the Turko-Austrian frontier, near Gradiska.

The steamer "Caroline," engaged for picking up the seventy miles of Persian Gulf cable, payed out from the "Calcutta," has had her machinery and fittings put on board, but her departure has been delayed by the late stormy weather. She went to sea on Sunday last, but on the following day put into Penzance with damaged machinery. Mr. F. C. Webb, C.E., superintends the necessary operations, and from his well-known experience in such matters, we hope soon to announce a successful issue to the expedition.

The progress of the French Atlantic cable continues in the same satisfactory manner. Of the main cable about 1,980 miles have been completed, and 600 miles of the St. Pierro and United States section. Coiling on board the "Great Eastern" is gradually going on, and up to the present time there is about 1,200 miles on board.

Soon after Easter it is anticipated the Government will bring in their "money bill" for purchasing the electric telegraphs of the kingdom. The arbitrations between the Post Office and the various companies is going on as fast as possible, and with the exception of that with Reuter's Telegram Company, are nearly concluded. The latter arbitration is lengthy, on account of the amount of scientific opinion brought forward respecting the quality and probable durability of the cable. It is necessary to determine the probable expenditure for future maintenance, before the amount for the purchase of the cable can be settled. On the completion of the arbitration, we hope to have some valuable information to place before our readers, on the probable duration of heavy submarine cables.

The forthcoming volunteer review will give an opportunity to our Royal Engineers' Field Telegraph Train of showing the enormous value to be derived from rapid signalling in the field, from point to point, of the position of a large army. A special party of Royal Engineers, under Captain Stotherd, R.E., comprising signallers, telegraphists, &c., with their waggons and apparatus, have received instructions from the War Office to proceed from head-quarters at Chatham to Dover, for the purpose of taking part in the volunteer review. On the troops arriving at their respective position, the telegraph lines will be laid down so that the general commanding may be able to despatch instructions to, and receive advice from, all points. For this purpose, signallers will be specially told off, to attend the various officers commanding divisions. We shall anxiously watch for the result of this practical trial of our Field

The following is an interesting experiment, lately performed by M. Poggendorff, upon the movement of mercury in a vacuum tube:—A tube of glass, provided with platinum wires at the ends, and containing some mercury, was exhausted, until as perfect a vacuum as possible could be obtained. In addition to which, by the application of great heat, the mercury was kept in a boiling state, until such time as, by inclining the tube, the mercury sounded sharp against the glass, a state that indicated the perfect condition of the vacuum. At a little distance from each end the tube was bent up at right angles, so that the platinum points were no longer in contact with the mercury. The tube was then hung, by means of hooks, to the electrodes of a Holtz machine, the tube being kept perfectly level, an operation rendered somewhat easy by the aid of the mercury inside. On passing a current from the machine through the tube, the mercury was immediately seen to travel with considerable speed from the negative to the positive pole, and whatever the direction of the current. the movement of the mercury was always to the positive pole. This movement was accompanied, but only visible in darkness, by a beautiful yellow fluorescent light on the negative end, and visible throughout the length of the platinum wire. The same light was also seen at the end of the mercury column, nearest the positive electrode, and continued to show throughout the forward movement of the mercury, until its arrival at the positive end. when it gave forth a brilliant light at the moment of arrival. A beautiful violet light, but not stratified, was visible throughout the rest of the tube occupied by the mercury.

#### PARLIAMENTARY NOTES.

IN the House of Commons, on the evening of this day week, Mr. Dixon asked whether an order for rifles had been received from the Indian authorities, and if so, for how many. From Mr. Cardwell's reply, it appears that it is intended to order 10,000 Snider rifles, and 1,200 arms of other classes, for India, to be supplied from the gun factories of London and Birmingham.

At the same sitting, Mr. Headlam asked the Under Secretary of State for Foreign Affairs what had been the result of the proceedings with the authorities of Spain concerning the destruction of the ship "Mermaid."

Mr. Otway said that the proceedings with regard to the "Mermaid" had been satisfactorily concluded. The work of the commissioners appointed to investigate the claim terminated on the 21st of last month. The decision was in favour of the claimants, and they were to receive £3,866 10s. 11d.; and, further, there was an agreement between the British and Spanish governments that the sum should be payable within 90 days. The decision had been considered satisfactory.

After this reply had been given, Mr. T. Hughes asked the Secretary of State for War whether a series of experiments were about to be made with a Whitworth 9-inch gun. Whether a new 9-inch gun was to be ordered of Mr. Whitworth, and, if so, at what price; and on what conditions as to delivery within a reasonable time. Whether any field guns were about to be ordered of Mr. Whitworth which were to be made of a peculiarly costly material, but otherwise in accordance with the existing Woolwich system; and, whether such experiments and orders were proposed or recommended by any professional department of the War Office or Admiralty.

miralty.

Mr. CARDWELL said that Mr. Whitworth had invented a new mode of making what was believed would be very valuable ordnance; and the Government applied to him for a small quantity of his material for use in the factory at Woolwich. He declined, however, to give the Government the use of his raw material; and he was then applied to, to know whether he would make them a gun of the size mentioned. He replied that he was willing to make the gun, and named the price. The Government had not at present accepted the offer, and consequently no arrangements had been entered into.

The question of the disposal of Portpatrick Harbour was opened by Sir J. Hay, who asked the President of the Board of Trade whether any

Digitized by Google

course had been determined upon with respect thereto in consequence of the commissioners of supply in Wigtownshire having declined to accept the terms offered with respect to it by the board.

Mr. AYRTON said that in consequence of the local authorities not thinking it worth their while to take charge of the harbour, it became necessary for the Government to consider what should be done with the harbour. Before they could arrive at any conclusion, it would be necessary to obtain the opinion of the legal advisers of the Government upon many important questions, and until that opinion had been received, no decision could be come to as to what would be done with the harbour.

On Friday evening, Mr. Samuelson put to the Postmaster General a string of questions respecting the transfer of the telegraphs. He asked hether a valuation had been made of the total sum which would become payable to the various sum which would become payable to the various telegraph and railway companies in the event of the State purchasing their interests under the permissive act of last session, and whether he would lay that valuation upon the table; whether it was not the case that a large additional outlay beyond that sum would be required in order to complete the scheme of telegraphic communication contemplated by the Post Office; whether the amount of such outlay had been ascertained, and would be communicated to the House; whether the Treasury had caused an estimate prepared of the cost of an entirely new and distinct system of telegraphic communication on the most improved plan, under the management of the Post Office, and would communicate such estimate to the House; and, whether or not it was the intention of the Treasury to recommend that Parliament should vote funds for carrying out the permissive act of last session, as well as the ad-ditional funds which would be required to complete the postal electric system as contemplated by that act.

The Marquis of HARTINGTON stated that the valuation of the total sum that would become payable to the various telegraph and railway companies in the event of the State purchasing their interest, under the permissive act of last session, was in course of being formed. The arbitrations were in progress, and it would be impossible to state the values precisely until the arbitrations were completed. With regard to the second question, the fact was that an additional, but not very large, outlay would be necessary to complete the telegraphic communication needed by the Post Office. The amount had been proxi-mately ascertained, and in the event of the arrangement going on the particulars should be communicated to the House. As to the third question, the Treasury had not caused any estimate to be prepared, so that it could not be laid before the House. As regarded the last question, it would be premature to state what were the intentions of the Government till the negotiations were further advanced. He should, however, in a few days, be enabled to explain what were the intentions of the Government.

On Tuesday evening Sir L. PALE asked the Secretary of State for War, when the Cadastral Survey of the mining districts of England would be completed, and especially the mining districts of Devon and Cornwall, where there were the the richest mines of tin, copper, and other ores. Mr. Cardwell said the Cadastral Survey of the

mining districts had been going on in Denbighshire and other counties, but at present it was not decided when that of Devon and Cornwall would be commenced.

At the same sitting Mr. Collins asked the Secretary of State for War whether it was the intention of the War Office to supply the Snider rifle to all the militia regiments for this year's training; and, if to any, to what regiments, and upon what principle such distsibution would take place.

Mr. CARDWELL said that 23 militia regiments would this year be supplied with the Snider rifle, amounting to 16,879. The regiments that would be selected to receive them would be those which were going to Aldershot and Shorncliffe, and also those regiments which, during the last three years, had devoted themselves to rifle practice.

VERY numerously attended meeting was held at A VERY numerously attended meeting was need at Oxford, on Saturday afternoon, when it was resolved to invite the Royal Agricultural Society to hold their meeting for 1870 in this city. It was stated that upwards of £3,200 had been promised towards the expenses of the meeting. THE METEOROLOGICAL SOCIETY.

HE ordinary meeting of this Society was held at the Institute of Civil Engineers, on Wednesday, the 17th inst., at seven p.m., Mr. James Glaisher, president, in the chair. Two candidates were proposed for admission into the Society. A paper was read by the Rev. F. W. Stow, M.A., of Tunbridge Wells, "On Comparative Solar Radia-The author in this paper complains of the tion " utter want of uniformity in the methods employed by different meteorologists in registering solar radiation. He should have known, however, and acknowledged that this is a matter which has been pointed out in Casella's edition of Well's essay "On Dew," by Mr. R. Strachan, F.M.S. This want of system is owing to two distinct classes of errorfirst, the almost endless variety of thermometers employed; second, the absence of any rule as to employed; second, the absence of any rule as to their exposure to the sun's rays. After carefully considering the nature of the reading given by an ordinary blackened bulb thermometer—that it consists of the heat of the sun's rays plus the accumulated heat of the air, and of the glass of the thermometer, Mr. Stow recommends a plan by means of which the latter two may be eliminated, and the former be obtained in a better condition for intercomparison with reports from other With regard to exposure, the writer, for various reasons, prefers a uniform height of 4ft. from the ground to one at less height. He concluded by asking the co-operation of observers in bringing about some method of working, which must be preferable to the absence of any method as at present. The President entered at great length into an account of his own researches in this direction in the years 1840-4. He had no objection to the proposals of Mr. Stow provided they were in addition to the methods at present employed by the best observers. He had found that a thermometer placed at a certain height above the ground was not affected at all by the sun's rays, and gave simply the temperature of the air. Mr. Symons supported the plan of placing the thermometers 4tt. from the ground as one easily adopted by all, and as it got rid of the effect of the mist always in existence more or less at 1ft. or 2ft. from the ground. A paper was then read by Mr. Glaisher "On the Storm of February 12, 1869." In this communication, the track is marked out of a small but violent storm which passed up the English Channel with great rapidity, and was marked in its southern half by a sudden and violent shift of wind from S.W. to N.W., accompanied in many places by torrents of rain. The storm was somewhat circular, and its centre passed a little S. of London at about 5 p.m., advancing at a rate of about thirty-five miles an hour. Mr. C. Meldrum, the secretary of the Mauritius Meteorological Society, then read a brief paper "On the Rotation of Winds in the South Indian Ocean," additional to that read at the previous meeting; and this, again, was followed by a second communication from Mr. Glaisher, "On the Meteorology of 1867 and 1868," in which he stated that such continuous and extreme heat had not been experienced at the Royal Observatory during a period of ninety-eight years, and he believed it had not been equalled in any part of the country during the last hundred years. No discussion, however, followed any of these papers, probably owing partly to the fact that no one knew certainly what papers were to be read before they entered the room, and partly to the endeavour to read too much at one partly to the endeavour to read too much at one meeting, and partly to inaudible reading. In a science, such as meteorology, wholesome criticism and hearty discussion are likely to be of great service, and should be more encouraged than they

The meeting closed at a little before 9 p.m., but not before the President had promised the members two important papers on rainfall, in connection with the moon's age; one by himself, the other, by Mr. G. Dines, who has already written on this subject. On the whole, this was one of the most interesting meetings that the Society has had for some years, and the next promises to be equally successful.

THE LARGEST ROPE IN THE WORLD.

latest one is so extraordinary as to merit special commemoration. The rope, which is intended for shipment abroad, is 11,000 yards long, measures 5½in. in circumference, and weighs over 60 tons. These figures are enough to take one's breath away; but when we come to see how the monster is built up, there is cause for still greater surprise. The rope (made of Messrs. Webster and Horsfall's patent charcoal wire, laid round a hemp centre) consists of six strands, with ten wires in each strand. Each wire measures 12,160 yards; so that the entire length of the wire reaches the enormous total of 726,000 yards, or 412½ miles. To this has to be added the length measures 12,100 yards; so that the entre length of the wire reaches the enormous total of 726,000 yards, or 412½ miles. To this has to be added the length of yarn used for the centre—namely, twenty-seven threads, made from Petersburg hemp, each thread measuring 15,000 yards, and giving a total length of 405,000 yards, or about 230 miles. Adding together the wire and yarn, we have a grand total of 1,181,000 yards, or 635 miles of material—all going to make up a monster wire and hemp rope a little under 6 miles long. Such a rope certainly has never yet been made; and we doubt whether, excepting in Birmingham, such a one could be made. As it lies in vast coils in Messra. Wright's machine-room, it looks like a miniature Atlantic cable, multiplied by five times the cable thickness. Of course such a rope will bear an enormous strain, and its capacity in this respect is increased by the perfection of the machinery employed in the manufacture, giving the strands an exactly uniform "lay," and imparting the regularity and the precise angle of "twist," which experience proves to possess the greatest resisting and holding proves to possess the greatest resisting and holding strength.

FOUR-WHEEL COUPLED PASSENGER ENGINE—PARIS AND ORLEANS RAIL-WAY.

OUR large two-page engraving is taken from the detail drawings of one of the most recent types of French passenger engines for the ordinary work of the Paris and Orleans line. The system of placing all the gear outside, even in coupled vastly popular abroad. We cannot but think it riding the hobby of accessibility of parts to death, and believe it to be practised more because foreign engine-drivers, like foreign grooms, are not so nice in keeping what is committed to their charge as are English drivers, than from any preference to the plan on mechanical grounds. From the nature of the engravings no description will be necessary. The following are the principal will be necessary. The following are the principal dimensions:—Length of fire-box (external), 4ft. 2jin.; breadth of fire-box (external), 3ft. 10in., (internal), 3ft. 4in.; height of fire-box from main level of bars to crown, 4ft.; diameter of barrel of boiler (external), 4ft. 1in.; number of tubes, 180; length of tubes between tube plates, 16ft. 5in.; diameter of tubes (internal), 1½in.; length of smoke-box, 3ft.; diameter of smoke-box 4ft. 6in. diameter of funnel, 16in.; smoke-box, 4ft. 6in.; diameter of funnel, 16in.; diameter of steam dome, 35in.; height of steam dome, 3ft. 8in.; diameter of cylinder, 16in.; length of stroke, 25.6in.; length of cylinder. (internal), 31in.; length of piston, 4-7in.; clearance (collective), 7in.; length of connecting rods, 5ft. 9in.; length of coupling rods, 6ft. 8½in.; diameter of driving wheels, 6ft. 6in.; diameter of leading wheels, 3ft. 11in.; diameter of driving axles, 7in., in bearings, 7.25in., in bosses, 7.8in.; length of bearings, 9.8in.; diameter of crank pin in boss, 5.1in.; in bearing, 4.7in., in bearing of coupling rods, 3.9in.; length of wheel base, 12ft. 10in.; maximum steam pressure, 130lb.; total length over buffers, 30ft. 2in.; area of grate surface, 14 square feet; area of fire-box heating surface, 74 square feet; area of tube heating surface, 1,350 square feet; area of total heating surface, 1,424 square feet; thickness of boiler plate (shell), 5-16in.; thickness of tube plate, 9-16in.; total width, clear of eccentrics, 8ft. 6in.; diameter of feed-pump plunger, 54in.; stroke of feed-pump plunger, 4in.

THE MANUFACTURE OF WATCHES AND CLOCKS,

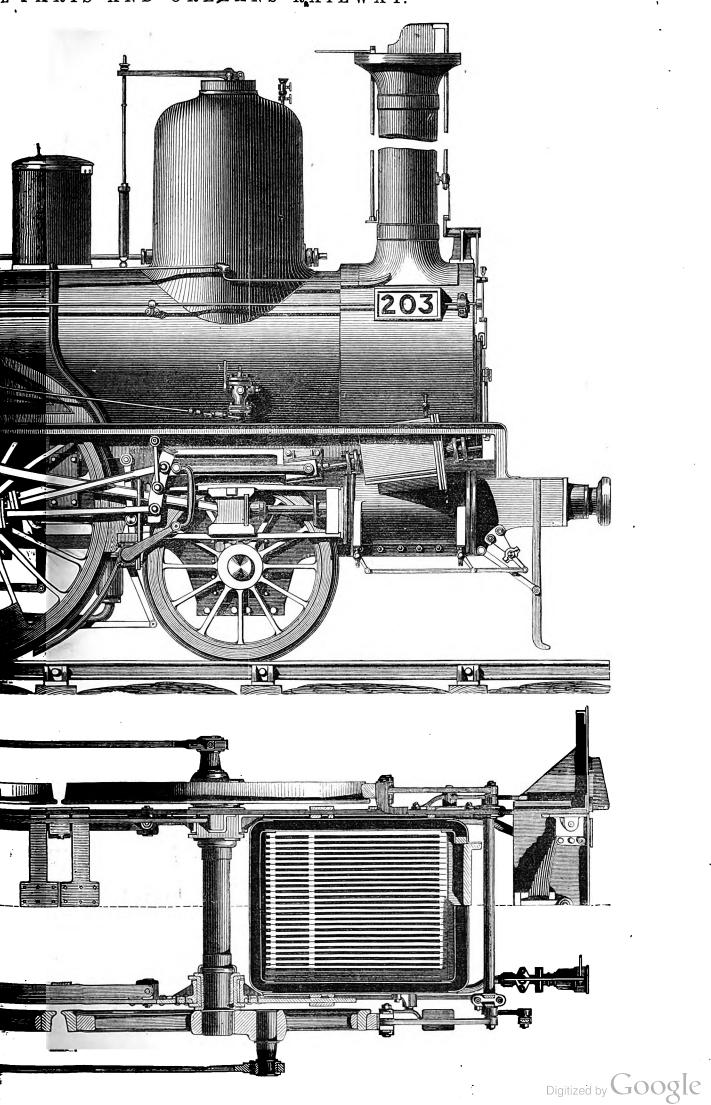

—A most interesting and instructive little work,
describing briefly, but with great clearness, the rise
and progress of watch and clock making, has just
been published by Mr. J. W. Benson, of 25, Old
Bond-street, 99, Westbourne-grove, and the City
Steam Factory, 58 and 60, Ludgate-hill. The book,
which is profusely illustrated, gives a full description of the various kinds of watches and clocks,
with their prices and no one should make a purphase The Language in the properties of the various kinds of watches and clocks, with their prices, and no one should make a purchase.

I also prices and cone should make a purchase with their prices, and no one should make a purchase with their prices, and no one should make a purchase.

I also prices and cone should make a purchase with their prices, and no one should make a purchase with their prices, and so one should make a purchase with their prices, and so one should make a purchase with their prices, and so one should make a purchase with their prices, and so one should make a purchase withing the not one

### HORIZONTAL OIL AGITATOR.

BY MR. JAMES RIGG.

#### FRICTION CLUTCH FOR DRIVING SHAFTS.

BY MR. F. W. KITSON AND MR. PIERRE CHALAS.

# HORIZONTAL OIL AGITATOR FOR MIXING LUBRICATION OILS.

THE demand long felt by manufacturers of all kinds employing machinery, for a really good lubricating oil, has led to the introduction of mineral oils on a large scale for that purpose. The very light specific gravity, however, of these oils has to a great extent confined their application as a lubricant to the lightest classes of cotton and silk machinery in consequence of the liability of the fluid from this cause to run from the bearings. Even for this purpose it has been with difficulty that the prejudices of manufacturers have been overcome. The result of many experiments which were tried was that by mixing these mineral oils with animal or vegetable oils the excessive fluidity was reduced, and they were found when mixed suitable for most lubricating purposes. Difficulty was, however, found in making a complete and intimate mechanical mixture, and various plans and contrivances have been adopted to thoroughly agitate and mix the mineral with the vegetable or animal oils. It is now admitted by oil manufacturers generally that the best form of agitator is the horizontal machine which is

illustrated in the annexed engraving, and which is manufactured by Mr. James Rigg, engineer, of Chester. It consists of a wrought-iron tank of suitable size, and having a semicircular bottom. A shaft passes through this tank, and carries longitudinal angle-iron beaters, as shown in the section. The oils required to be mixed are filled through the lid, which is made sufficiently tight to prevent any waste during the process of agitation. The machine is then set in motion, and in the course of a very short period the particles of oil are so thoroughly agitated that all liability to separate from each other is rendered impossible. By this means, the lubricating properties of the mineral oil are retained, and the difficulty caused by its running off the bearings is entirely obviated. A pump may be attached to the agitator, and used for throwing the mixed oils into the various store tanks, from which they may be drawn for use. The invention of this agitator has been the foundation of a most important branch of the oil trade, which is increasing in a surprising degree, and there can be no doubt that the mixtures of lubricating oils of which the mineral element forms the chief part, surpass any that have hitherto been discovered.

#### FRICTION CLUTCH.

MR. F. W. KITSON, the well-known engineer of Leeds, and Mr. Pierre Chalas, engineer, of the same place, have recently patented some improvements in friction clutches for driving shafts. It is a novel method of bringing the friction surfaces into contact so as to communicate motion from the shaft of the engine to the driving shaft of the machinery it is intended to actuate. In the accompanying engraving, we have shown an arrangement of mechanism which the inventors have in practice found most convenient. Fig. 1 is a side elevation of the friction clutch; fig. 2, a plan view; and fig. 3, an end elevation of the same. Fig. 4 is a vertical section of the hydraulic cylinder and the friction apparatus connected therewith, drawn upon an enlarged scale, and taken in the line Y Z of fig. 5, which is an end view of the clutch.

scale, and taken in the line Y Z of hg. 5, which is an end view of the clutch.

The flywheel a of the engine is keyed on a shaft shown by dots in fig. 2, and may be termed the driving shaft. On this shaft is also keyed the toothed wheel b and also the shallow hydraulic cylinder c shown detached at figs. 4 and  $4^a$ . Mounted loosely on this same shaft is another

toothed wheel b1, which is made with a flat friction surface  $b^*$ , seen best at fig. 4. d is the friction disc, which is secured to the pistons e c of the hydraulic cylinder, the water space of which is of annular form, as indicated by dots at fig. 4. The a water passage a\*, water or other liquid is supplied through this passage to the cylinder e from an accumulator or an hydraulic pump. A transverse passage c\* is drilled through the side of the driving shaft into the water passage a\*, so that upon opening a communeation between the pump or accumulator and the hydraulic cylinder c, water at a very high pressure will be admitted through the passages  $a^*$  and behind the pistons e, and will force them forward, and thus bring the friction plate d attached thereto into contact with the friction disc  $b^*$  on the side of the wheel or pulley  $b^1$ , which will thus be driven by the flywheel or driving shaft of the motive-power engine and through the intermediate wheel  $b^2$  to a similar toothed wheel  $b^3$ which is keyed on to the working shaft f, which will, therefore, be driven in the direction of the

Of course, if it be desired to adapt the invention to reversing gear so as to be able to drive the machine (to be actuated) in either direction, then there must be a double set of friction clutches, as shown at fig. 2. The reversing friction clutch will be similar in construction to the hydraulic clutch just described, but will act upon separate wheels. which are driven by the flywheel or other motive shaft in opposite directions.

It has been explained that the flywheel a and toothed wheel b being both keyed on to their shaft will constantly rotate in the direction indicated by the arrows, and by means of the friction clutch and toothed gearing just described will cause the working shaft f to rotate in the direction of the arrow marked thereon. But if the friction clutch e be released, the wheel  $b^1$  will be loose on the shaft, and as it then will not drive the wheels  $b \ge and b^3$ , no motion will be imparted to the working shaft f, and the latter will, therefore, remain stationary, although the wheel b which is mounted thereon will be driven in the direction of the arrow. If, now, it be desired to drive the working shaft f in a direction opposite to that indicated by the arrow, it will only necessary to allow water from the hydraulic pump or accumulator to enter the cylinder c 1, so force the friction disc  $d^{-1}$  up against the friction surface  $b^*$  of the wheel  $b^{-4}$ . This wheel, which was rotating loosely on the shaft, will, by means of the friction clutch  $d^{-1}$ , be firmly gripped, and will carry round with it the shaft f in the direction indicated by the arrow on the wheel.

In order to render the pistons of the hydraulic cylinder c perfectly water-tight, a thick ring or annular plate of vulcanized india-rubber is secured on the back of the pistons e.e., and is forced up against a shoulder in the cylinder, and when the pressure of the water is taken off the pistons, the elastic india-rubber ring g will force back the pistons and the friction disc d and thus release the clutch. It will be seen that if the working shaft is required to be driven always in the same direction, only one set of clutches will be required. namely, that shown at  $c^{-1}$   $d^{-1}$ , fig. 2. The wheel  $b^{-4}$  which carries one of the friction discs  $b^{*}$  will be constantly driven by the wheel b on the driving shaft, while the other disc d 1 is secured to the piston of the hydraulic cylinder  $c^{-1}$ , which is keyed on to the shaft f which is intended to be driven. We may add that this friction clutch has been regularly at work in Mr. Kitson's establishment— the Monk Bridge Iron Works, Leeds—for some time past. It has given such satisfaction that it is now being applied, on a large scale, to the reversing gear of heavy plate mills. It acts very perfectly, without noise or shock.

THE report of the committee of the Buffalo City Council, detailing negotations with the manager of the Grand Trunk Railway, relative to the proposed international bridge connecting Buffalo and Fort Erie, states that the city of Buffalo is to guarantee 6 per cent. interest on 1,350,000 dollars of capital for fifteen years; and, in return, the citizens of Buffalo are to be allowed to take an amount of stock sufficient to give them the control of the company. sufficient to give them the control of the company. There is a promise, too, that when the bridge is completed, the Grand Trunk Company will pay 50,000 dollars for the use of it. That promise, we "Toronto Globe," suppose, has yet to be ratified in England. If the other railway companies that are expected to use the bridge, do as well as Mr. Brydges promises that the Grand Trunk shall do, the people of Buffalo will not be likely to lose very much by the guarantee.

AMERICAN LOCOMOTIVES AND ROLLING STOCK.

BY MR. ZERAH COLBURN, M. INST. C.E. (Concluded from page 207.)

OF the mechanical details of American loco-O motives, considered apart from the details already touched upon, much might be said. There were differences, and they were numerous, but they involved no important principles. The chilled cast-iron wheel, however, for engine and tender bogies, and especially for carriages and waggons, deserved mention. No wrought-iron wheels, so far as the author could learn, were now employed in the States, unless in a few cases for engine driving-wheels; and wrought-iron wheels, at first exclusively adopted, had been wholly abandoned on the Grand Trunk and the Great Western railways of Canada. The cast-iron wheels were not only much cheaper, but they were more durable, and, if not safer, were at least equally safe. The wheels employed for passenger carriages were 2ft. 9in. in diameter, and weighed 5cwt. The bogic wheels of engines, tenders, and goods waggons were generally 2ft. 6in. in diameter, and varied in weight from 4cwt. to 4\chicut. They were cast of special mixtures of the best qualities of iron, the requisite conditions being great absolute strength to resist both sudden and progressive strains, and property of taking a deep and uniform chill. But little of the cast iron employed for wheels had a tensile strength of less than fifteen tons per square inch, and it broke with a fracture, almost suggestive of fibre, and of a dark grey colour, but when chilled of a silvery whiteness. The chilled wheels ran from two to six and even seven years, according to the traffic, before becoming so much worn as to require removal, representing a service of from 80,000 miles to 200,000 miles. Engine driving-wheels of from 4ft. to 5ft. in diameter, had been cast with chilled faces, thus requiring no tyres, and chilled tyres, from 4ft. to 6ft. in diameter, and 31 in. thick, had been extensively and successfully employed at fair rates of speed, say twenty-eight miles an hour.

Wood was almost exclusively employed as fuel, except upon two or three important lines in the coal districts, until within the last ten or twelve Iron fireboxes and copper tubes were then generally adopted; but for burning coal, steel fireboxes and iron tubes were now used. Of upwards of 400 steel fireboxes in the engines of the Pennsylvania Central Railway, some had been in use for six years or more. The tubes were set without ferrules, and very little trouble, as the author was The tubes were set without informed, was experienced either from leaking or cracking. It was worthy of observation, that the cracking. It was worthy of observation, that evil of "furrowing," by no means uncommon in the States, and no other explanation appeared available, than that the thinner iron employed there permitted of a certain elasticity in the structure of the beiler, sufficient to prevent the localization or accumulation of bending or other strains at particular points, or rather upon particular lines of resistance.

What were now understood as steep, or exceptionally steep, gradients were rare in the States. Some instances of such were cited, and it was mentioned that, in July, 1836, one of Norris's engines, weighing 6 tons 8½ cwt., and drawing behind it, including tender, a load of 8 tons 11½ cwt., ascended an incline near Philadelphia of 1 in 14, and 933 yards long, at an average speed of  $15\frac{3}{4}$ miles an hour. The nominal weight on the driving wheels was 31 tons, but it was believed that a portion of the weight of the tender was made to bear upon the footplate, thus increasing the adhesion.

With regard to the expense of maintenance, it was stated that the average cost of engine repairs in the States, exclusive of those renewals which amounted to building a new engine, might be taken as a maximum at 10 cents currency per train mile. equal to 33d. in coin. Of this, the absolute difference in the cost of labour and materials would account for nearly or quite 1d., leaving 24d. to 8d as the cost at English prices. Again, the manner in which these repairs were conducted showed a want of system and organization, and the shops were not fitted with some of the appliances considered essential in this country. Whatever economy in repairs might attach to the American engines was due, after allowing for the moderate working speed, to three causes only, viz., the use of the bogie, of chilled cast-iron bogie wheels (which could be renewed at a cost of from £2 to £2 10s. each, after allowing for the value of the wheel taken out as old iron), and of steel or iron fireboxes and iron tubes. About twelve or fifteen years ago, the average mileage of American engines, taking the full stock of the leading lines,

was not above 15,000 miles yearly,probably not far short of 20,000 miles, and on some lines it might be even more.

There remained the consideration of the carriage and waggon stock, with reference to its mechanical peculiarities and its commercial relation to traffic. The earlier American carriages were made upon the English model, but it was found, not only that a short wheel base was required for six-chain and nine-chain curves, but also that side buffers aggravated the difficulty. The bogic, already in use on the engines, was, therefore, adopted for the car-riages, and it was soon discovered that the length of body could be considerably increased, and that the longer it was the steadier it became. But the long bodies precluded the use of side buffers, and so central buffer with a loose coupling took their place. End doors afforded an obvious means of economy in the structure of the carriage, and left the whole depth of the body below the windowsills available for any combination of trussing. most effective for carrying a comparatively long The end doors, with a continuous passage span. throughout the carriage, afforded obvious facilities for communication. The central passage required an additional width of carriage, and from 9ft. to 9ft. Gin. was a common outside width; while, in some cases, even on the narrow gauge, a width of more than 10ft. had been adopted. These widths allowed seats for four passengers across, and for the longitudinal passage dividing the seats. The seats had reversible backs, so that the passenger might face either way, the carriages running in either direction without turning.

It was undeniable that the seating was not so roomy and comfortable as in an English first-class carriage, and that, as compared with a secondclass carriage, there was a certain loss of space. It was equally undeniable that such carriages could never answer for short traffic lines, where forty, fifty, or more passengers had to leave, and as many more to enter in a minute or a minute and a half. The long body, however, with end doors and platforms, possessed obvious mechanical advantages. Its length gave steadiness, and the depth below the window sills afforded ample opportunity for providing vertical stiffness with-out undue increase of weight. There were no cross partitions; there were but two doors, where English carriages would require, for the number of seats, according to class, from twelve to twenty-six; there was much less sash and glazing. while there was at the same time more light : there was an important saving in respect of draw-springs, buffers, buffer-rods, and screw couplings, and there was every facility for applying brakes, as was always done in the States, to every wheel in the train, either from the Platform of the carriages themselves or from engine. It was an advantage of the long body. with its corresponding weight and number of wheels, that the application of the brakes, how-ever suddenly, did not produce the jolting of which passengers complained so much when the same thing was attempted upon English carriages. Passenger carriages upon the double bogie plan were made of various lengths, from 45ft, to 60ft., exclusive of the additional 2ft. 6in. at each end for platform and covering porch. They accommodated from sixty to eighty-four passengers, and weighed, empty, twelve tons and upwards, or from sixteen tons to twenty-two tons leaded. Some notice was next given of Pullman's hotel car, and of the carriage, built by Messrs. Winans, for the Emperor of Russia. The improvements which had been effected in the engine and other bogies were then alluded to, and a description was given of the oil-tight axle-box, as well as of Loughridge's and of Creamer's continuous

In comparing the cost of maintenance of American carriage and waggon stock with that on English lines, many considerations were to be regarded. To say that the cost, in 1867, on the 1.612 miles of railway in the State of Massachusetts, for a train mileage of nearly 10,000,000 miles, was 6.55 cents, currency, or about 21d. coin train mile, did not permit of any according train mile, did not accurate In the States, the average number deductions. of passengers continuously carried over the whole distance made by a train was generally onehalf greater than in England, although the proportion of dead weight to live load was probably nearly as high as in this country. The speed was less, and there remained the fact that labour and nearly all materials were much dearer. On the other hand, there was a considerable saving in the use of chilled cast-iron wheels, such a thing as a wheel-turning lathe for carriage or waggon stock being unknown in the States. The

Digitized by GOOGLE

maintenance of buffer and draw springs cost much less. The maintenance of the carriage bodies was cheaper, from their great strength and simplicity of structure, and from the fact that

there were no side doors to slam.

One objection to the use of chilled cast-iron wheele, not referred to in the earlier portion of the paper, was that, being almost necessarily of the disc form, their weight increased in a ratio nearly as the square of the diameter, and thus the largest railway carriage wheels yet employed in the States were but 3ft., and this size was long ago discontinued in preference for 2ft. 9in. In the case of cast-iron spoked wheels, the chill was less hard opposite the ends of the spokes than elsewhere, and thus they soon showed flat spots.

It might be said, in conclusion, that if American railway practice were in any or many respects more daring than that which prevailed in this country, failure, if not too often repeated, was regarded in the cousin country as a misfortune, where here, unless it proceeded from causes absolutely beyond provision, it was rightly regarded as a fault, a misdemeanour, or even a

# FARADAY AND HIS SCIENTIFIC DISCOVERIES.

By Mr. W. H. PREECE.

A N interesting lecture, illustrated by experiments A material recture, inustrated by experiments, was delivered in connection with the Southampton Polytechnic Institution at the Hartley Hall, on Wednesday evening, by Mr. W. H. Preece, on "Faraday." Mr. Alderman Stebbing (the president on wednesday evening, by Mr. W. H. Prece, on "Faraday." Mr. Alderman Stebbing (the president of the institution) occupied the chair, and there was a very numerous attendance. The lecturer commenced by stating that he was going to tell them of the life of the son of a blacksmith, Michael Faraday, who was born on the 22nd of September, 1791, and died on the 25th of August, 1867; The greatest experimental philosopher of this or any other ago. His education consisted of little more than that of the elements of reading, writing, and arithmetic, acquired at a common day school; but our progress in life does not depend so much upon what we learn at school as upon what we teach ourselves at home, self-education is the secret of all success. At the age of thirteen Faraday was apprenticed to a bookbinder and stationer, and he took every advantage of the opportunities which he thus possessed of examining beautiful. secret of an success. At the age of thriteen rariads was apprenticed to a bookbinder and stationer, and he took every advantage of the opportunities which he thus possessed of examining books. The perusal of "Watts on the Mind" first made him think, and that was the commencement of his career. His attention was turned to the science which he adorned so brightly by an article on electricity in an encyclopædia which he was engaged to bind, and he delighted also to read Mrs. Marcett's work on chemistry. Faraday, writing in 1858, said that in the books which he read after work he found the beginning of his philosophy, and he added that there were two that specially helped him—the "Encyclopædia Britannica," from which he obtained his first notions of electricity, and Mrs. Marsett's work on chemistry. Faraday could trust to facts, and always cross-examine assertions, and in these lay the whole secret of his success in life. Speaking of his early experiments, Faraday said, "I made such simple experiments in chemistry as could be defrayed his early experiments, Faraday said, "I made such simple experiments in chemistry as could be defrayed in their expense by a few pence per week, and I also constructed an electric machine, first with a glass phial, and afterwards with a real cylinder, as well as other electrical apparatus of a corresponding kind." He also attended some evening lectures on attend with publication with the sum of the sum o kind." He also attended some evening lectures on natural philosophy; and how he employed himself when seventeen or eighteen years of age might be gathered from a manuscript volume of his, which he called the philosophical miscellany, and which consisted of a collection of notes of occurrences in the arts and sciences, collected from the public papers, magazines, and other works. Faraday attracted the notice of Sir Humphrey Davy—also a self-made man—who succeeded in obtaining for him a situation at the Royal Institution, in 1813, as laboratory assistant, at a salary of 25s. a week; and Faraday remained connected with the institution till the day of his death, fifty-four years afterwards, of his death, fifty-four years afterwards,

When twenty-two years of age he travelled with When twenty-two years of age he travelled with Sir Humphrey Davy on the continent, and, in 1816, Faraday published his first paper in the "Quarterly Journal of Science," relating to an analysis which he had made of some native caustic lime from Italy. At this time he rendered himself so useful and invaluable that his salary was raised to £100 a-year. In 1821 he married, and on Christmas Day of that year he succeeded in making one of his original electrical experiments, that of the rotation of a magnet around a current of electricity. The particular net around a current of electricity. The particular branch of eletricity to which this experiment be-longed only dated from the commencement of the present century—and was sometimes called galvanism and sometimes voltaic electricity. It is produced through a piece of zinc. Zinc, copper, acids, and other chemical solutions, combined in various proportions and orders, form a battery, a term applied

te several cells. Take a simple glass, in which they would place a piece of zinc, and opposite it a piece of copper, and then filling the glass with water diluted with acid, they got a galvanic cell, and by various methods he could tell that they had got electricity flowing there, for if he put his tongue there he could feel it. If he put two other wires in connection with the two first, many of them would see contain motion on the table, and it was simulated. nection with the two first, many of them would see a certain motion on the table; and it was simply by repeating this process that they obtained electricity for telegraphic and other purposes. But how did they make this evident? By showing the great fundamental property of the electric current. That current invariably has a kind of sympathy (displayed in action) with things that associate themselves in a different way; and whenever a wire possesses a current of electricity it causes the magnet to set itself at right angles, while it can be made to rotate round the wire. The mutual action of

inagnet to set itself at right angles, while it can be made to rotate round the wire. The mutual action of electric currents and magnets was of the greatest significance to scientific men, and it is remarkable as being the subject of the first experiment that Faraday effected in electricity.

In 1824 he received the Victoria Cross of scientific men; he was made an F.R.S.; from 1824 to 1829 papers, lectures and researches in almost every chemical and physicial subject occupied his attention, and in the last named year he received the blue ribbon of the lecture table; he was selected to deliver the Bakerran lecture before the Royal Society. the Bakerran lecture before the Royal Society. In 1830 Faraday had accomplished enough to establish himself upon the roll of scientific fame. He had made two great discoveries, that of electric magnetic rotation, and the condensation of various gases into liquids. In one of Faraday's first experiments on the liquefaction of gas no less than thirteen pieces of glass were driven by an explosion into his eye. About this time he discovered benzone, the basis of aniline; and in 1831 he commenced those experiments at researches which immortalized him, and which he continued without intermission him, and which he continued without intermission till 1856. They consisted of twenty-nine series, which are published in three massive volumes—the most valuable addition to electrical lore ever produced—upsetting many well established notions, discovering innumerable fresh properties, proving the truth of contested facts, inventing new methods of operation, and bequeathing to posterity new sources of power.

sources of power.

The lecture then glanced at a few points connected with the science of electricity as treated upon by Faraday in the three volumes he had mentioned, by raraday in the three volumes he had mentioned, and having referred to the principle of induction, drew the attention of his hearers to the distinction between static and dynamic electricity, showing that thunder and lightning were a form of static electricity. The dynamic form of electricity is distinguished chiefly by the great property it possesses of producing magnetism. A specimen of Faraday's induction coil was displayed to view. It Faraday's induction coil was displayed to view. It is constructed so that when the current has passed through one wire, we have evidence of another current in the wire alongside of it. And it was this curious fact that first attracted Faraday's attention. Faraday, at the time he was making all these discoveries, was only receiving £100 a year; but in 1833 he obtained an extra £100 owing to the munificence of Mr. Fuller, who endowed a professorship to that amount. Faraday not only showed the connection between electricity and magnetism, but he also brought his mind to bear on the power of electricity in relation to chemical action. magnetism, but he also brought his mind to bear on the power of electricity in relation to chemical action. Whenever a current of electricity is allowed to pass through any chemical compound, it at once tears that compound asunder into its constituent parts; and Faraday showed that the amount of chemical action which takes place is exactly equivalent to the strength of the current which passes through.

In 1863 Faraday was appointed to an important post in the Trinity House, and the amount of work he did in examining cotton, oils, and in various

post in the Trinity House, and the amount of work he did in examining cotton, oils, and in various ways, was perfectly astounding; while his electric light was now being used for our lighthouses; it was already in existence in one of them, and was being applied to five more. In 1841 Faraday found it necessary to go abroad for the sake of his health, and spent some time in Switzerland. Many illustrations of his character were given, and his method of transacting business was commended to all. His instructions to his instrument maker were:—I. Whatever you make for me charge such a price as Whatever you make for me charge such a price as to make it a pleasure for you to work for me.

Never let a bill run over three months. 3. When you want your money come to me. He was an other than the control of the c

before Him who is Lord of all, and hope to wait patiently for the time and mode of release according to His Divine Word—his gracious and precious promise, whereby His people are made partakers of the Divine nature." He had not long to wait, for in August, 1867, this great, this good, this brilliant man passed silently and gently away, without a murnur or a pang, to that "country from whose bourne no traveller returns."—(Loud applause.)

The experiments exhibited were of a highly interesting and gratifying character, and at the close of the lecture Mr. Alderman Stebbing proposed a cordial vote of shanks to Mr. Precee for his excellent lecture, which was carried by acclamation, and the company separated.

We may add that the experiments exhibited were of a highly interesting and gratifying character.

of a highly interesting and gratifying character.

#### THE ROYAL POLYTECHNIC INSTITUTION.

DROFESSOR PEPPER and his able staff are preparing a variety of novelties for the Easter holiday folks. The most prominent and interesting of these is a new induction coil, which is the largest that has ever been made. This coil is 6ft. long and 18in. in diameter; the primary wire is 3,370 yards, and the secondary wire 150 miles 3,370 yards, and the secondary wire 150 miles long. It has a condenser of 1,500 superficial feet, and the apparatus weighs just 1 ton. On Tuesday evening Professor Pepper gave a private view of this splendid apparatus, and made a series of tentathis spicial apparatus, and made a series of tenta-tive experiments, which served to illustrate its power, although it was not then in thorough working order. It gave sparks of great beauty 30in. in length; these sparks were varied, some being straight and others feathered. Sparks were also sent along a wire, arranged in a pattern across the end of the theatre. Experiments were made with twolve Loyden jars, 18in. in height, and containing 40 superficial feet. With these wires of iron, zinc, brass, and copper were rapidly melted. The induction coil—which was manufactured by Mr. Apps, of the Strand—will prove one of the leading attractions at the Polytechnic during the approaching holidays.

# RELATION BETWEEN METEORS AND COMETS.

A N interesting scientific fact is becoming the subject of attention, as to the relation between meteors and comets. Dr. Bedford (a gentleman well known in the scientific world, and who stood for the city of Chester at the last general election), published and entered at Stationers' Hall, in 1854, a pamphlet, entitled "New Theories of the Universe," in which and entered at Stationers Hall, in 1894, a pamphlet, entitled "New Theories of the Universe," in which he stated that there was a relation between meteors and comets, and that both move in orbits. This discovery was made by a careful comparison of the records of these bodies from the earliest times. Also, in refutation of the then existing theory as to the physical constitution of the solar orb, he affirmed advanced views as to its igneous nature, which were at the time, like the theory of Galileo, scouted by the other philosophers of the day. Recent experiments, however, says the "Wiltshire County Mirror," have not only proved the truth of Dr. Bedford's theories, but they have been acknowledged, for two successive years (1867-68), by Professor Pepper, in his Lenten Lectures on Astronomy, at the Royal Polytechnic Institution, London, as forming the groundwork "of the grandest system of astronomical science," and "well worthy of being studied." The subject is now looked upon as highly important in a scientific point of view, and is likely to lead to a complete revolution in the science of astronomy. complete revolution in the science of astronomy.

### EARTHQUAKE-PROOF ARCHITECTURE.

THE recent earthquakes on the Pacific coast have necessitated the adoption of some THE recent earthquakes on the Pacific coast have necessitated the adoption of some new style of building in that section of the country. Mere bricks shells will not stand many heavy land shocks, so the "New York Times" states, that the architects of San Francisco are now busy over earthquake-proof plans of architecture. The last severe earthquake in that city cracked a large number of brick walls, which have had to be braced together with iron rods to make them in any way safe. A very little heavier shock would have tumbled them in ruins. The fact that these sensations may come at any time, has somewhat shaken the faith of the people in the security of their brick houses. One of the new plans proposed is to build a compact wooden frame structure, and surround it with brick walls. The frame would secure it against falling, and the walls would render it fireproof. A large publishing-house in San Francisco is soon to erect a store upon this plan. Another method 2. Never let a bill run over three months. 3. When a minently religious man. The spirit of the Gospel, inculcated by the pious example of his parente, ran through his whole life, and showed that the pursuit of science was not incompatible with Christian conduct. When Faraday had reached the allotted span of life—threescore years and ten—gradually and surely his powers failed him, he became feebler and feebler, and his bright, cheerful face was missed from his accustomed seat. In the summer of 1867, at Hampton Court—at a house provided by her Majesty herself—he sat at his window viewing the beautiful clouds tinged by the rich purple of the setting sun, when a friend from London asked him how he was, "Just waiting," he replied; "just waiting." This he more fully expressed—"I bow this matter, and a new field is open for the ingenuity

of architects. Anybody who will guarantee to put up a house that will stand an ordinary earthquake without damage, whether it be built of wood, stone, iron, paper, or rubber, can make his fortune on the Pacific coast. As soon as such buildings can be devised, earthquake insurance companies will doubt-less be established there to satisfy individuals who have not complete faith in the stability of real estate on the Pacific coast.

# Correspondence.

DETERIORATION OF SUBMARINE CABLES. TO THE EDITOR OF THE "MECHANICS' MAGAZINE." SIR,-Will you allow me to make some further

SIR,—Will you allow me to make some further remarks on the durability of submarine cables.

The Dover and Calais cable is perhaps the very worst instance that can be taken of a submarine cable. It is the first cable that was ever laid and kept in working order, and thus cannot have the benefit of the improvements which have been introduced in the manufacture of cables, and which have so greatly added to their durability. It was laid under a narrow and shallow channel; consequently, is liable to be continually injured, if not broken, by anchors; and, what is even more important, the movement of the water caused by waves must, where it is so shallow, extend to the bed of the Channel where the cable lies; this movement in the water causes friction, which gradually wears the cable away, and friction, which gradually wears the cable away, and lets the water into it. This, besides producing decay, affects, if not entirely destroys, insulation. You state that the Dover and Calais cable has been repaired about thirty or forty times, and that

You state that the Dover and Calais cable has been repaired about thirty or forty times, and that there is now only a little more than one-half of the original cable down. I will assume that, during the seventeen and a-half years it has been laid, the repairs and renewals have averaged 30 per cent. of the receipts (which is six times the ordinary per centage), and the working expenses another 5 per centage), and the working expenses another 5 per cent.; this would only be 35 per cent. of the receipts, whereas the entire working expenses of the Electric and International Telegraph Company for the year ending June 30, 1868, were 57½ per cent. Thus, to maintain and work a cable under the worst possible circumstances costs 22½ per cent. less of the receipts than is required with the very best land lines.

The arguments in my pamphlet with regard to the relative cost of maintaining land lines and submarine cables referred more particularly to deep sea cables, and I still think that cables laid at such depths as the Atlantic cables stand but little chance of being broken and deteriorated. There cannot possibly be any movement in the water where it is so deep. Anchors are not likely to be lowered to such depths, and icebergs do not measure miles above the surface

Anchors are not likely to be lowered to such depths, and icebergs do not measure miles above the surface of the water, consequently will not measure miles below the surface; and, as the chief ingredient of a cable is gutta-percha, which is supposed to be impervious to the effects of water, it is only the decay of time that has to be feared. The decay of time is so slow that I do not think anybody need trouble themselves about the destruction of the Atlantic cables for the next fifty or sixty years. I may say that I think the shallow water portions of the Atlantic and other cables will often require repairs and renewals for the reasons abovementioned.

reasons abovementioned.

Hoping you will again find space for my remarks,

—I am Sir, yours, &c.,

J. WAGSTAFF BLUNDELL.

49, Chancery-lane, London, March 22.

[We give insertion to Mr. Blundell's letter with
no further observation than that the writer appears
to be beyond the reach of conviction.—Ed. M. M.]

### A TWIN GUN.

A TWIN GUN.

SIR,—On reading in your last issue a description of a twin gun by Mr. H. W. Reveley, my first impressions were that it, at any rate, had the claim of novelty, if not of efficiency. Still, I had my doubts on the matter, for I fancied I had seen a similar weapon described elsewhere before. On looking over my papers, I find this to be the case. During the American war, certain reports upon the proceedings of the United States Government appeared over the signature of "Orpheus C Kerr" in a New York weekly paper. In one of these reports (which have since been published collectively by Mr. Hotten, of Piccadilly), trials of various newly-invented guns are described. I send you the report in question, which is dated August, 1861, and from which you will see that the following is faithfully transcribed:—

"The next weapon tried was Jinks' double back-action revolving cannon for ferry boats. It consists of a heavy bronze tube, revolving on a pivot, with

of a heavy bronze tube, revolving on a pivot, with both ends open, and a touch hole in the middle. both ends open, and a touch hole in the middle. While one gunner puts a load in at one end, another puts in a load at the other end, and one touch hole serves for both. Upon applying the match, the gun is whirled swiftly round on a pivot, and both balls fly out in circles, causing great slaughter on both sides. This terrible engine was aimed at the target with great accuracy, but as the gunner had a large family dependent on him for support, he refused to apply the match."

Mr. Reveley's gun has two touch holes, and the chambers are separated by a wall of metal. With these two slight exceptions, I do not see much difference between Mr. Reveley's and Mr. Jinks' guns. I am, Sir, yours, &c., March 22. VIGILANS.

THE SEA TORPEDO.
SIR,—I have received a letter from Mr. Romaine in acknowledgment of and in reply to my letter on the above subject to Mr. Childers of the 6th inst., a copy of which you inserted in your last issue. I do not know that it is the correct thing to publish Mr. Romaine's letter; I am, however, I presume, at liberty to state what I think of its tenour. I would, therefore, remark that the employment of torpedoes in future wars is clearly admitted by the Admiralty—the arm is acknowledged by our war authorities as an arm adopted; and the Admiralty assure us that the arm is so well understood that it can be immethe arm is so well understood that it can be immediately brought into operation in the event of war. If such is the fact, I cannot understand the policy of continuing to build monster war vessels. Taking a common sense view of the matter, it appears to me that such a course is unfair to our country, and, moreover, cruel to our seamen; for, should we be engaged in war with a maritime state, our seamen will, in our monster vessels, have, at a great disadvantage, to encounter an arm in which the hostile state will, in all probability, be better practised than ourselves

to encounter an arm in which the hostile state will, in all probability, be better practised than ourselves by reason of being in possession of a really practicable sea torpedo for sea service, with vessels, also, adapted to its application.

With regard to the personal knowledge which the individuals of the Board of Admiralty have of the sea torpedo, I should state that Mr. Childers, the First Lord, has not seen it in the water, nor has he even seen it out of the water; he cannot, therefore, know anything personally of its management or performance. The First Sea Lord has no more knowledge of the subject than Mr. Childers; the Junior Sea Lord had accidentally a glimpse of the sea torpedo. But Rear-Admiral Astley, C.K., C.B., Acting Director-General of Naval Ordnance, pro-Acting Director-General of Naval Ordnance, pronounced the sea torpedo, after having thoroughly inspected it, the best he had seen.—I am, Sir, yours, C., John Harvey, Captain R.N., 5, Keynsham Parade, Cheltenham, March 20.

# Megal Intelligence.

VICE-CHANCELLOR'S COURT. FEB. 19. (Before Vice-Chancellor Sir W. M. JAMES.) SPARAGNAPANE V. COOMBS.

Mr. E. Cutler moved ex parte on behalf of the plaintiff in this case for an injunction to restrain an infringement of his registered design for oysters

The plaintiff, who is a wholesale confectioner in Bishopsgate-street, invented in October an ornamental sweetmeat purporting to represent the real native of Whitstable, and had registered his design, which included a motto containing the usual coup-The ornamental oyster proved a great succe and, according to the allegations, the defendant, who is a confectioner, also earrying on business in Bishopsgate-street, was infringing the plaintiff's copyright by selling ornamental oysters closely resembling those manufactured by plaintiff, but, according to the usual allegation, of a very inferior quality and lower in price.

The Vice-Chancellon (after having been re-

ferred to the Copyright of Designs Act, 5 and 6 Victoria, cap. 100,) granted an interim injunction, upon the usual undertaking by the plaintiff to be answerable in damages.

This registration was effected by Messrs. Robertson, Brooman, and Co.

### TO CORRESPONDENTS.

THE MECHANICS MAGAZINE is sent post-free to subscribers of £1 is. 8d. yearly, or 10s. 10d. half-yearly, payable in

of £1 is. 8d. yearly, or 10s. 10d. nan-yearly, payeous advance.
Alliliterary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.
To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.
We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

faith. ED. M. M.
Advertisements are inserted in the MECHANICS' MAGA-ZINE, at the rate of 6d, per line, or 6d, per line for 13 inser-tions, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertise-ments.

P. G. M.'s letter is so illegible that neither we nor our rinters—who, like ourselves, are accustomed to queer riting—could decipher it.

# Habal, Military, and Gunnery Items.

Admiralty order has been issued for the assembling of a reserve squadron at Portland during the Whitsuntide holidays. The cruise, it is stated, will probably last a fortnight.

18 stated, will probably last a fortnight.

The Hamburg-American Company's screw steamship "Holsatia," Captain H. Rhiers, which arrived last Thursday evening from New York, made the quickest run ever accomplished from that port to Southampton. She left New York at 5 p.m. on the 9th inst, and arrived off Cowes at 8 p.m. on the 18th, making the passage in 8 days 22 hours, allowing for difference of time.

The Board of Trade have awarded a telescope to Captain T. Van Eyk, of the Dutch schooner "Adriana Wilhelminas," for his services to the crew of the sloop "Luna," of Hull. The "Luna" was stranded on the Hasborough Sand on the 12th was stranded on the Hasborough Sand on the 12th ult. The crew escaped in their own boat, and, after seventeen hours exposure, were picked up in an exhausted state by the "Adriana Wilhelmina," and were landed on the 15th ult. at Hellevoetsluis.

MESSRS. W. DENNY and BROTHERS have launched Messrs. W. Denny and Brothers have launched an iron screw of 1,700 tons, named the "Glenartney." She will be fitted by Messrs. Denny and Co. with direct-acting surface-condensing engines of 300 horse power nominal. Messrs. W. Simons and Co., of the London Works, Renfrew, have launched an iron screw of 600 tons burden, and of the following dimensions:—Length. 170ft; breadth, 25ft; and depth, 21ft. This steamer is constructed with a spar-deck fore and aft, so as to protect cattle, goods, passengers, &c., in the wildest weather.

The contract for the erection of a new lighthouse and lighthouse-keepers residence at Souter Point, near Sunderland, has been let to Mr. Todd, builder, of South Shields, for £8,000.

THE death of Mr. William Patterson, who for many years carried on an extensive business as a many years carried on an extensive outsiness as shipbuilder at Bristol, is announced as having taken place at Liverpool, to which town Mr. Patterson had recently removed. Mr. Patterson was builder of "Great Western," the first steamer that ever crossed the Atlantic. He also built the steamer "Great Britain.

THE following iron-screw steamers belonging to THE following iron-screw steamers belonging to the Romlay Marine have been advertised for sale at Bomlay on April 1st, viz:—The "Earl Canning," 661 tons, and 150 horse power, built at Port Glasgow by Robert Duncan and Co. in 1866; "Lord Elphinstone," 654 tons, and 150 horse power, built at Port Glasgow by Blackwood and Gordon in 1866; and the "Sir John Laurence," 577 tons, and 70 horse power, built in London by Simpson and Co. in 1865. The makers of the engines of the two first named vessels are Messrs. Blackwood and Gordon, while Messrs. Rennie of London made those Gordon, while Messrs. Rennie of London made those of the "Sir John Laurence."

DURING the month ending January 31 in the current year 2,959 vessels entered, and, 2,954 vessels cleared at ports in the United Kingdom, representing totals respectively of 912,739 tons and 1,027,628 tons. Of the foreign vessels entered, 43 were Russian, 14 Swedish, 84 Norwegian, 90 Danish, 78 Prussian, 26 Hanoverian, 122 Dutch, 260 French, 30 Spanish, 42 Austrain, and 27 American. These numbers ahow an increase, as compared with the corresponding month of last year, by 708 vessels Spanish, 42 Austrain, and 27 American. These numbers ahow an increase, as compared with the corresponding month of last year, by 708 vessels and 120,075 tons. An analysis of those entered shows that 1,951 were British and 1,008 foreign vessels, and of those cleared that 2,027 were British and 927 Foreign. A total of 261 vessels arrived during the same month from British possessions, of which 40 came from North America, 78 from the East Indies, Including Ceylon, Singapor, and Mauritius, 9 from Australia, 11 from the West Indies, and 123 from other ports, representing a decrease of 51 vessels as compared with the January statistics of last year. A total of 334 vessels cleared to British possessions, 8 of which were bound to North America, 91 to the East Indies, 25 to Australia, 47 to the West Indies, and 163 to various other ports, showing also a slight comparative decrease. A total of 10,773 vessels were entered and 10,413 cleared of those employed in the intercourse between Gteat Britain and Ireland. course between Gteat Britain and Ireland.

# Miscellanea.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending March 20, was 2,563. Total number since the opening of the Museum, free daily (May 12, 1858), 1,522,067.

THE Metropolitan Board of Works have elected r. T. W. Keates to the post of gas examiner for a Mr. certain portion of the metropolis, under the terms of the gas legislation of 1868.

THE Oastler memorial, which consists of a colossal figure in bronze, of the late Mr. Richard Oastler and two factory children, is to be inaugurated at Bradford, on Saturday, the 15th of May

At the meeting of the Institution of Civil Engineers on Tuesday, the 23rd inst., Mr. C. H. Gregory, President, in the chair, his Majesty Napoleon III., Emperor of the French, was elected by acclamation an honorary member.

M. DE LESSEPS has at length been rewarded for his skill and perseverance. On Wednesday week, the waters of the Mediterranean were admitted into the Bitter Lakes with complete success, and the Suez Canal may now be considered un fait accompli. We congratulate M. de Lesseps on the successful world to this great undartaking. result of his great undertaking.

MR. JAMES SIMPSON, an eniment hydraulic engineer, and once president of the Institute of Civil Engineers, died recently at Surbiton. Under his direction, the water supply of many of the continental towns was carried out, and the Bristol Waterworks was planned by him, and constructed under his carreit related. his superintendence.

As a sample of the honorarium paid to artists who are at the head of their respective classes, it may be worth recording that Mr. Sims Reeves, the vocalist, and M. Blondin, the rope-dancer, each receive a hundred pounds or guineas, for a performance at the Crystal Palace. Mr. Charles. Dickens, it is said, eceives the same sum for each of his readings in London.

THE number of visitors to the South Kensington Museum during the week ending March 20, 1869, was—on Monday, Tuesday, and Saturday (free) from 10 a.m. to 10 p.m., 9,438; Meyrick and other galleries, 1,830; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 5 p.m., 1,752; Meyrick and other galleries, 133; total, 13,153. Average of corresponding week in former years, 11,209. Total from opening of Museum, 8,242,277.

THE chair which is left vacant in the French Academy, section of music, by the death of M. Berlioz, is No. 5. and was occupied successively by two comedians, Preville and Grandmesnile; then by Berton, in 1816, and by Adolphe Adam in 1844. The others are at present filled by M.M. Auber, Carafa, Ambroise Thomas, Reber and Gounod, Among the candidates to succeed M. Berlioz are mentioned M.M. Felicien David, Victor Masse Maillart, and Rever. Maillart, and Reyer.

GLASS panes, constantly exposed to the action of the sun and rain, are soon deteriorated, as the potash or soda they contain combines with the carbonic acid of the air. A whitish opakeness is the consequence of this action, and in order to make the pane return to its pristine transparency it should first be rubbed with dilute hydrochloric acid, and then cleaned with moistened whiting. By this means it is said that glass in an extreme state of decomposition may be completely restored.

An agent of an American paper-mill has been in New Brunswick purchasing wood, to be shipped to Philadelpha. The "St. John's Telegraph" says the agent has already contracted for 3,000 cords of white birch and spruce wood, which is being got out on the Bay of Fundy Shore, more particularly in Westmorland. Samples of excellent paper made from poplar may be seen at that office. The New Brunswick wood will go into the States free of duty, being for manufacturing purpose.

a recent meeting of the Manchester Literary At a recent meeting of the Manchester Literary and Philosophical Society, a nest of one of the mason apiders from St. Thomas was exhibited by Mr. Sidebothom. Its form was that of an irregular tube, composed of clay and bits of stone, rather more than 3in. long, and 1sin. diameter, this is lined with fine silk. The cover is formed of similar clay and bits of stone, and has a very beautiful and durable hinge of silk fibres. When the nest is built in a hollow on the ground, and the lid closed, it would be next to impossible to detect it, and the lid fits so beautifully that no rein could an enemy that no rain could penetrate, nor could an enemy without great difficulty open the lid from the outside.

THE imported sparrows are good colonists. In spite of the tremendous snow storms they still manage to keep up undiminished numbers. A Canadian paper states that there are now about twenty birds, which may be seen daily in and about the Artillery Barracks. Their utility is more particularly observable at this season of the year; the hot sun vivilies insect life for several hours of the day, when from their semi-torpid state they become an easy prey to birds: the eyes too, of the cateran easy prey to birds; the eggs, too, of the cater-pillar tribes are approaching maturity. A little bird, therefore, such as the sparrow or the black-capped titmouse, can commit great havor among what will become insects at a later period. an easy prey to birds; the eggs, too, of the caterpillar tribes are approaching maturity. A little bird, therefore, such as the sparrow or the black-capped titmouse, can commit great havoc among what will become insects at a later period.

The use of petroleum as fuel seems to have given excellent results applied to domestic purposes. A vapour cooking stove, invented by Mr. Thome, has

been exhibited to the American Society for the Advancement of Science and Art. The fuel used was Advancement of Science and Art. The ruce used was petroleum refuse, and the danger of explosion is obviated by the use of wire-gauze, as in miners' safety-lamps. The oven is said to attain a baking heat in from one to two minutes, and bread, apples, and potatoes were baked, as well as a stake cooked, in the presence of the meeting. Several who had tried the stove, expressed a favourable opinion as to its operation. operation.

At the last monthly general meeting of the Zoological Society of London, Mr. Robert Hudson, F.R.S. in the chair. Sir Joseph R. B. Bailey, M.P., Colonel Alexander R. Manson, Major Thomas Bott, Captain Alexander P. B. Baillie, Captain Maxwell Goad, Miss Helen Scott, Mrs. F. Keymer, and Messrs. Edwin Jarrett, J. W. Humphrey, Charles Dod, Edmund Green, Zouch Turton, John Lambort, Charles C. Downes, John Rowland, Robert A. Newbon, Thomas G. Barclay, John Colebrooke, Robert H. Hall, R. L. Henry, Edward Bower, David J. French, John K. Smythies, John Sykes, William R. Mitchell, George Plomer, Frederick H. T. Streatfield, J. F. Barelli, and Charles Wheen were elected Fellows of the society. Twenty-nine candidates for the Fellowship were proposed and ordered to be balloted for at the next monthly meeting. AT the last monthly general meeting of the Zoolomonthly meeting.

The exports of coal from the United Kingdom in the first month of this year showed some decline as compared with January 1868. Thus the total shipments in January were 623,647 tons, as compared with 675,170 tons in January, 1868, and 560,890 tons in January, 1867. The exports of coal to France in January were 167,914 tons, as compared with 170,895 tons in January, 1868, and 159,312 tons in January, 1867. The exports increased in January to Russia, the Hause Towns, Italy, and the United States; but they decreased to Denmark, Sweden, Holland, France, Spain, Brazil, and British India. The value of the coal exported in January was £315,341, as compared with £356,121 in January, 1868, and £301,014 in January, 1867. In these totals, France figured for £75,809, £80,678, and 76,894 respectfully. THE exports of coal from the United Kingdom in respectfully.

Carding engines. Dated September 4, 1868.
The patentees propose to fix thin flat guides between the
doffers and the strippers. These guides are placed between
the rings on the doffers with the flat side towards the
doffer. By this means, the slivers are more effectually
separated. They also place two rollers (fluted or plain)
between the stripper and the twisting straps, to take the
slivers from the stripper and carry them to the twisting
straps. They also place guides between these rollers and
the twisting straps for the slivers to pass between. By
these means, there are less breakages and better work
produced.—Patent abandoned.

wheel; the cam actuates a parallel rod, imparting thereto a horizontal two-and-fro motion. The rod gives motion to a catch lever, working on a stud near the middle of such lever, the lower part of which has a slot hole.— Patent abandoned

2732 J. SPROUL, Hadley. Water power. Dated September 4, 1868.

The patentee proposes to return to the employment of the old-fashioned waterwheel, in lieu of steam, for working machinery.—Patent abandoned.

2733 W. E. Newton, Chancery-lane. Thermomaters.
Dated September 4, 1863.
The object of this is to indicate automatically, and at any distance, changes of the thermometer proper, which actuate dials, bells, or other indicating apparatus, thus showing the variations of temperature.—Patent completed

2734 J. PARKER, Camberwell. Motive power. Dated September 4, 1868.

The patentee proposes to reheat or superheat steam and air, combined together, by forming the pipe by which the steam and air is conducted from the nozzles to the cylinder or receiver with one or more angles, elbows, bends, or curves.—Patent abandoned.

2735 S. SHARROCK, Liverpool. Metal telegraph posts
Dated September 4, 1868.
The central uprights of telegraph posts are made of iron
or steel, in convenient lengths, of tubular form, the lengths
being attached by means of flanges, which only require
bolting or riveting together. In the case of telegraph
masts, as well as the signal masts, where considerable
height is required, the patentee trusses or braces the
central uprights by means of iron or steel truss rods
which are tightened and adjusted by means of stretching
screws.—Patent completed.

screws.—Patent completed.

2736 T. Perkins, Hitchin. Straw elevators. Dated September 4, 1868.

In order to elevate a cut crop from the ground on which it lies, on to a waggon or cart, the patentee employs an elevator, consisting of a trough-like frame, having, as in an ordinary elevator, pulleys at each end of the trough, around which endless chains pass. These chains carry cross laths, with teeth upon them, which travel along the trough. The trough is creeted in an inclined position, and with its lower end foremost it is drawn over the land. Inclined rake teeth are fixed at the front end of the trough, and these points rest on the land. The crop, as the machine meets it, rises up the inclined teeth, and from the top of this incline the elevating chains take the crop, and carry it to the top of the trough, where it is discharged.—Patent abandoned.

discharged.—Patent abandoned.

2737 J. Pickering, Durham. Raising and lowering Dated September 5, 1868.

The patentee uses two pulley wheels, which are placed together on a spindle, in a frame. These two pulley wheels are made of unequal diameters. The periphery of the small wheel is made with sunken chambers, to receive the links of a single chain, which hangs down to raise weights. Sometimes the two wheels are made separate, with grooved or bevelled faces, whereby the one is secured to the other by friction. On the other side of the large or driving wheel a clutch is fitted, which is made in the form of a wedge or inclined plane, on the face. Against this is another clutch, fastened to the spindle or axis, fitting the face of the former named wedge or incline plane, and to this clutch a ratchet wheel is fitted, with a pawl, to cause the same to run one way only. This ratchet wheel, together with the clutch, prevents the weight, when raised, from slipping down.—Patent completed.

2738 R. BANKS, York. Floor dog or cramp. Dated Sep-

2738 R. BANKS, York. Floor dog or cramp. Dated September 5, 1868.

On the joist, or other support, the patentee places a frame, having at one side a stationary plate, provided with a number of pointed pins; the plate is pinched up to the joist or support, by means of a lever and eccentric, or by a screw, so that the frame shall be effectually fastened.—Patent abandoned.

2739 T. Howcroff and A. M'Gregor, Lancaster Reaping machines. Dated September 5, 1868.

This relates, first, to reaping machines, having one main driving wheel only. The gearing actuating the knives is contained within and shielded by a dished or dome-shaped cover or case, cast together and forming part of the framework of the machine. The lower and forward end of this framework is cut with a flange, to which the finger bar and sleeve are bolted.—Patent abandoned.

J. L. PULVERMACHER, Regent-street. Electricity.

Dated September 5, 1868.

The patentee forms cylinders from open worked copper Dated September 6, 1868.

The patentee forms cylinders from open worked copper plates, or from copper wires worked into the form of cylinders; these cylinders are provided with tubes to allow of their being connected together by insulated bent pins or wires to form a chain; these pins or wires put the copper cylinders into metallic contact with solid or hollow zinc cylinders into metallic contact with solid or hollow zinc cylinders after the latter have been provided with threads or other insulating material; the zinc cylinders are sufficiently long to extend beyond both ends of the copper cylinders. In order to keep up the supply of the exciting liquid to the elements thus formed, and at the same time keep dry the outer surface of the copper, a caoutchouc tube is employed carrying small T-shaped pipes, which are placed on the tops of the zinc cylinders, but do not touch each other. Exciting liquid is supplied to the caoutchouc tube, and issues through holes into the T-pipes and runs down continuously between each zinc cylinders and the surrounding copper. The elements can be connected so as to form a chain, the links of which are insulated from each other; both the zinc and the copper cylinders are provided with movable rings, each having a projection at one part of its circumference, by means of which the contacta, either in the sense of tension or of quantity, may be established, by moving the rings into a position to bring all the copper cylinders and all the zinc cylinders into contact, whereby electrical quantity is obtained, or by moving the rings so that the projection on the ring of each zinc cylinder ot the adjoining elements, whereby voltaic contact and intensity are obtained.—Patent completed.

2741 J. Sloper, Walbrook. Perforating tickets. Dated September 5, 1868.

2741 J. SLOPER, Walbrook. Perforating tickets. Dated September 5, 1868.

The patentee employs a hanging or vibrating frame, and

aforcing red or plunger, carried and guided longitudinally by cams. The die or matrix is caused to move towards the forcing red or plunger, such motion being derived from the red itself through lever arrangements in connection, the effect being to halve or reduce the extent of motion of the red, which would otherwise be necessary, and so to produce a quick and powerful action.—Patent abandoned.

produce a quick and powerful action.—Patent abandoned.

2742 W. H. Chispin, Stratford. Artificial fuel. Dated
September 5, 1863.

The fuel is formed by taking about 1 ton of coal in a
pulverized state, and adding thereto about 6 or 7 per cent.,
by weight, of pitch, the same having been previously dissolved in about an equal weight of crossote or "heavy"
oil, resulting from the distillation of coal tar, or in any
hydrocarbon fluid or fluids possessing similar solvent
powers. The coal and pitch having been thus combined,
about 3 per cent., by weight, of lime, and 3 per cent. of
chioride of sodium (common salt) are added.—Patent
completed. completed.

completed.

2743 W. E. Newton, Chancery-lane. Ships' compasses.
Dated September 5, 1868.

This consists of a combination of three or more systems of magnetized needles or bars attached to one or more axles, and arranged in different horizontal planes. The first or upper system of magnetized needles consists of two bars parallel to each other, with similar poles in the same direction, and parallel to the systems of magnetized needles below, when there is no disturbing cause to move them from the magnetized needles or bars consists of two (or more) magnetized needles or bars thed in a frame which may be attached to a vertical axle (or shaft) and he movable up and down the same, or the frame may be adapted to uprights or pendant rods on which it may be amoved up and down.—Patent completed.

2744 T. Wilson, Birmingham. Firearms. Dated Sep-

adapted to uprights or pendant rods on which it may be moved up and down.—Patent completed.

2744 T. Wilson, Birmingham, Firearms. Dated September 5, 1868.

To the trigger guard at the rear of the trigger is jointed a hinged plate or flap, the plate or flap being similar to an ordinary sight leaf, and capable of a similar backward and forward movement. In order to secure or fix the trigger, the plate or flap is turned forward so that its free end rests or abuts against the shank of the trigger, thereby preventing the movement of the trigger, and, consequently, the accidental discharge of the firearm. It also consists in constructing the foot or upper end of the trigger so as to make it bear firmly upon the sear guide spring, whereby the movement of the spring is prevented, while the shank of the trigger remains fixed by the free end of the plate or fap. It consists, further, in constructing the extractors of breech-loading firearms provided with sliding bolts or closers to work in a lengitudinal groove or opening in the rear and upper side of the breech shoe, and operating the extractors by the sliding motions of the breech bolt (acting against shoulders formed on the bodies of the extractors) in opening and closing the breech. It consists, further, of the following mode of securing the hinged blocks of breech-loading firearms during the discharge of the said firearms. A raised piece is affixed to the forward end of the breech shoe into which a bolt takes upon closing the breech block. The bolt in the block works in a longitudinal slot formed in the block, and is released by the pressure of the thrub on opening the breech for reloading the firearm.—Patent completed. sure of the thumb on opening the breech for reloading the firearm.—Patent completed.

frearm.—Patent completed.

2745 W. TATLOCK and C. N. ABELSETH, Chancery-lane.

Gus apparatus. Dated September 5, 1868.

This consists in the peculiar construction of the gas generator through which a continuous current of atmospheric air is forced, all of such air being brought into contact with the liquid with which the generator is charged, and thereby impregnated with the inflammable matter contained in the same. In the centre of a tank is placed a perforated pipe or hollow shaft which, where it passes through the head or end of the tank, is provided with a stuffing box made in the usual way to allow the shaft to revolve freely in the tank without leaking. Upon this shaft, inside the tank; a placed a perforated elydinder, made less in diameter than the tank, to leave a space around it and between it and the tank; outside of this cylinder another cylinder is fitted, which is also perforated, a slight space being left between the two cylinders. This space is filled with cotton batting or other suitable material.—Patent abandoned. -Patent abandoned.

2746 H. COWING, Euston-square. Traction engine. Dated September 7, 1868

September 7, 1868.

The patentee proposes to construct the engine upon a platform or framework to be mounted on two or more wheels of 12ft, or 14ft, in diameter; other wheels, pivoted to separate frames, so as to turn in any direction for steering the apparatus, are also employed. Upon the platform is placed a high pre-sure engine with suitable boiler and furnace, provided with revolving bars and arrangements for feeding the furnace with fuel. The bars, by their motion, clean themselves from clinkers, and by keeping the fuel in slight agitation or motion, prevent the coal from coking. The fire is introduced at the upper part, and the boiler being short, any unevenness in the road or soil will not cause the tubes to be uncovered. The water is to be taken in at bottom, and as it follows a serpentine course, the heat from the fire will be thoroughly taken up and the fuel economized.—Patent abandoned.

2747, J. Woop, New Jersov. Enthem from state. Detail

2747 J. Wood, New Jersey. Railway frog plates. Dated

September 7, 1868.

This consists in making the "froz plates" movab instead of the points or switches.—Patent completed.

Instead of the points or switches.—Patent completed.

2748 C. E. Brooman, Fleet-street. Burning oils. (A communication). Dated September 7, 1868.

This comprises, first, a particular system or mode of feeding burners in lighting apparatus with inheral oils or essences; and, second, a particular system or arrangement of circular burner for the combustion of the oils and essences. The system of feeding the lighting apparatus is based on the capillarity obtained by a main or first conducting wick, extending for any length, and fitted herizontally in a straight or bent tube, on which the burners are placed; the ends or other part of this wick dip into a chamber containing the essence or oil, so that by its capillarity the wick becomes impregnated with it for its whole length. From each burner a vertical wick leads to the main wick, and thereby also becomes impregnated by capillarity with the essence or oil. The keeping at a constant level of the liquid in the chamber into which the ends of the main wick dip is obtained by a reservoir or bottle-like receptacle, with a valve placed over each chamber. The burner employed is preferably circular; it

is composed of several concentric tubes, with an inverted circulation of air; its wick is fixed, and the regulation of the light is effected by a movable glass carrier.—Patent abandoned.

2749 H. M. LEE, Manchester. Visiting cards. Dat 2749 H. M. LEE, Manchester. Visiting cards. Dated September 7, 1868.

The patentee proposes to fit card cases with a chain, so that they can be suspended.—Patent completed.

2750 U. A. MASSELON, Issoudun, France. Burning bricks. Dated September 7, 1868.

The patentee constructs the kiln of a rectangular form with an arched roof with two or more chimneys, and provides two or more furnaces, the doors of which are protected. In the centre of the kiln and at each side thereof tected. In the centre of the kiln and at each side thereof dwarf walls are arranged, running from front to back thereof, such dwarf walls being inclined and slightly higher at the ends remotest from the furnaces. Upon these dwarf walls bricks or other articles are placed to a suitable height. The heated products of combustion circulate and penetrate through and between the mass other articles, and then pass away by suitable flues; spaces are formed in the walls of the kiln, with passages communicating between such spaces and the exterior of the kiln, in order to facilitate the escape of the gases given off in the burning.—Patent completed.

2751 J. JOYNSON, Manchester. Muffs. Dated September 7, 1868.
This consists in constructing "muffs" with projecting ears, gauntlets, or wrist protectors. A hole is also made through which the handle of an umbrella can be inserted. —Patent abandoned.

2752 G. DAVIES, Lincoln's Inn. Water meters. Dated

2732 G. DAVER, Lincoln's Inn. Water meters. Dated September 7, 1868.

This consists mainly of two cylinders, which serve as measures of capacity, and two distributing cylinders, all placed in juxtaposition and parallel to each other, beneath a crank shaft, by means of which the four connecting reds for working the pistons and distributing valves are actuated.—Patent completed.

actuated.—Patent completed.

2753 W.T. CARRINGTON, Westminster. Capstans. Dated September 7, 1868.

The patentee forms upon the barrel of the capstan a series of two or more circular grooves, and combines with the capstan an auxiliary barrel, placed a short distance from the capstan, and having grooves corresponding with those on the capstan. The rope or chain to be hauled in is first acted upon by the capstan, from whence it passes over the first grooves of the auxiliary barrel to the second groove of the capstan, and so on, the slack end being drawn off in the ordinary manner.—Patent completed.

2754 V. WANOSTROCHT, Walbrook, Gunpowder mills

2754 V. WANOSTROCHT, Walbrook. Gunpowder mills. Dated September 7, 1868.

This consists in placing the roofs of gunpowder mills on columns constructed after the manner of telescopes, and in such manner that the roof will easily slide up or down, and so, in case of explosion, instead of being shattered, it will be blown open, and pormit the ready escape of the gases.—Patent abandoned.

2755 A. V. Newron, Chancery-lane. Knitting. Dated September 7, 1868.
The patentee employs a grooved rotating needle cylinder, a needle operating cam, and spring looped needles. The looped end of the needles springs down into a groove in the body under the end. An auxiliary grooved wheel or cylinder is employed to act in conjunction with the cylinder for taking the loop into its grooves.—Patent completed. completed.

2756 E. E. B. J. V. H. STOKES, Birmingham. Pearli ornaments. Dated September 7, 1868. The patentee proposes to utilize pearl in making orna-ments.—Patent abandoned.

2757 J. C. WALKER, Hackney Wick. Washing coppers.
Dated September 5, 1868.
The patentee proposes to employ an inner vessel, into which the articles to be washed are placed. This inner vessel is formed with holes, so that when lifted by handles the water is free to run from it. Slotted perforations are formed near the top, so that a circulation of the water is kept up.—Patent completed.

kept up.—Patent completed.

2758 S. R. TUCKER, Chancery-lane. Rotary engines.
Dated September 7, 1968.
This consists in the novel arrangement of parts for obtaining the continuous action of the steam or other fluid upon the rotating piston or pistons, and other parts in connection of the cylinder and pistons, and other parts in connection therewith; also in the combination of the cylinder and pistons with the main shaft and with a rotating disc or plate, which is fixed on the shaft to carry the pistons. The invention also consists in the peculiar arrangement of the admission and exhaust ports and passages in combination with the disc and pistons.—Patent abandoned.

2759 C. HOLLAND, Chicago, U.S.A. Artificial tiles. Dated

2759 C. HOLLAND, Chicago, U.S.A. Artificial tiles. Dated

2759 C. HOLLAND, Chicago, U.S.A. Artificial tiles. Dated September 7, 1868.

This consists, first, in the intimate combination and cementation of particles of silex, aluminum, calcium, or other mineral substances, singly or admixed in various proportions, by the use of an alkaline solution of gum sheliac; second, in the combination of black or red oxide of iron or of asphaltum, with lime or cement and sand to produce a composition adapted to useful and ornamental purposes as with or without shellac.—Patent completed.

2760 F. Andoe, Swansea. Fire escape. Dated Septem-

ber 8, 1868.

This consists of a box or receptacle for one or more per-This consists of a box or receptacle for one or more persons to stand or place themselves within, and having cords, ropes, or tackle, for suspending it, passed through gripping pulleys or rollers, one pair at either end (or side) of and near to top thereof, and thence by other pulleys or rollers guided, and brought to pass out of the box or receptacle together, or nearly together, at or near to the bottom thereof, and furnished with a check brake for pressing on the tackle or rollers, or some of them, to prevent a too rapid descent.—Patent abandoned.

2761 J. JONES, Durham. Iron furnaces. Dated Septem-

2761 J. JONES, Durham. Iron furnaces. Dated September 8, 1863.

The patentee erects a series of furnaces in advance of each other, constructed with openings on either side, provided with proper doors, so that the pile or slab of iron to be heated can be introduced at one side of the furnace, and then withdrawn from such furnace, at the other side, in a line or thereabouts with the opening of the furnace, into which the slab or piece of iron is to be next introduced.

Between each and beyond the last of the furnaces, rolls are arranged in such a position that the slab or piece of iron is carried directly from the furnaces to the rolls, and then from the rolls to the furnaces, and so on.—Patent completed.

2762 J. BURDETT, Harrow-road. Making bricks. Dated

2762 J. BURDETT, Harrow-rosu. Making with a September 8, 1868.

This consists in making bricks from clay of the required consistency, by forcing it into dies, after which they are separated by cutting wires fitted in a frame; they are then carried on by rollers over another roller, which dips in oil, so that the lower side of the brick is covered with oil; they then pass on the receiving loads.—Patent completed.

2763 A. R. STOCKER and J. A. EDBLEY. Lamb's Conduitairest. Stoppers for bottles. Dated September 8, 1868. Hollow stoppers are composed of sheet metals of exceedingly thin gauge, as will be elastic and springy.—Patent completed.

2764 A. J. Fraser, Holloway. Locks. Dated Septem ber 8, 1868.

This consists in the employment of a ring, and a series of spring bolts, fitted inside the ring, arranged so that the bolt cannot be acted upon by any other than the special key made for it.—Patent completed.

2765 G. LOWRY, Salford. Hackling fibres. Dated Sep-

2765 G. Lowry, Salford. Hacking norm. Dated September 8, 1868.

This consists in the employment of a cam pulley for increasing the number of strokes of the doffing knife. The cam is formed by cutting a suitably shaped groove upon the face of the pulley. The pulley rotates upon a stud or spindle fixed to the side of the machine, and is driven by a strap from a pulley in the machine. A stud or pin that is fixed to the doffing knife is inserted in this groove, when the pulley rotates, the cam rises and lowers the knife two or more times for each revolution of the pulley, according to the shape of the cam.—Patent abandond.

2766 J.Aub, Paris. Spill holders. Dated September 8,

2766 J. Aub, Paris. Spill holders. Dated September 8,

This consists in forming a vase of earthenware, glass, crystal, or any other suitable substance, the form of which is such as to admit of its bearing around its exterior surface, and in its centre, a number of medallions or advertisements so placed that they can be renewed or replaced by others when desired.—Patent abandoned.

2767 P. J. SOULAGE, Paris. Breast pin. Dated Septem-

ber S, 1868.

The pin is constructed of two parts, which when in situ, form a specie of bow, the pin taking the place of the spring, and the point entering an aperture in one end of the bow, prevents its becoming accidentally detached.—Patent abandoned.

2768 E. COTTAM, Battersea. Horse shoes. Dated September 8, 1868.

tember 8, 1868.

This consists, first, in rolling two bars by the same rolls, the two bars when rolled being united. The rolls are formed with raised surfaces and indentations corresponding to the section of iron required for the shoe; second, it consists in preparing horses feet for the reception of the shoes by rasps. The rasps are constructed with an edge flange along one or more of their sides, which enables the shoer to prepare and level the wall of the foot to any desired width, without injuring the sole or frog of the foot—Patent completed.

2769 J. STEWART and J. NICHOLSON, Poplar. Engines

2769 J. STEWART and J. NICHOLSON, Poplar. Engines and raires. Dated September 8, 1868.

Two or more cylinders are so arranged that their pistoms act in unison, the steam acting upon them in the propering direction, until the whole of its useful effect is expended in the production of power and energy. No expension gear is necessary, nor is the steam used twice over, but acts at the same time on each piston, and in the same direction. By the use of a retaining valve between the exhaust and the condenser, or between the exhaust and the atmosphere, according to the form of engine employed, the compression may be regulated to any required degree.—Patent completed.

completed.

2770 S. E. CLARKE, Apsley-cross, Somerset. Fireplaces.
Dated September 8, 1868.

The patentee constructs and arranges the flues of open freplaces in such a manner that the heat, or a portion of the heat, from the burning fuel may be made to heat an oven, and hot plate, and a boiler, so that baking and various cooking and other domestic operations may be carried on simultaneously.—Patent completed.

2771 S. BENJAMIN, Bayswater. Blind for cabs, &c. Dated

September 8, 1868.
This consists of a semicircular blind or glazed sash, which is drawn out from between the roof and false lining of the same inside the cab.—Patent abandoned.

2772 O. WARSOP, Nottingham. Obtaining motire power. Dated September 8, 1863.

This consists of a steam boller and an engine; the engine works an air pump or pumps, drawing in cold air and forcing it through a coll of pipes, or other suitable chamber, heated by a furnace, and from this heated coil or chamber the air passes into the boiler, and is caused to rise in a finely divided state through the water therein. The air and steam together pass from the boiler to work the engine.—Patent completed.

the engine.—Patent completed.

2773 E. Johnson, Brighton. Muffs, cuffs, and collars Dated September 8, 1868.

The patentee proposes to make articles of pheasant feathers, applied in an entirely novel manner. In making a muff, the foundation, or muff proper, is first completed, and the feathers (which are attached by sewing singly or otherwise, to a silk or other backing) are then applied thereon, so as to partially envelope the muff foundation. The feathers are arranged so that they may depend or hang downwards on either side of the muff, meeting at the top (where the smallest feathers are placed) in a seam, which is concealed by a braid or other suitable ormanent. The long feathers are placed at the lower edges of the backing, on either side of the muff, and tend to impart a drooping appearance to the same. When the small or breast feathers only are used they are made to follow the contour of the muff, instead of depending, as before described, on each side.—Patent completed.

2774 J. Milleward, B. Birmingham. Builers. Dated Sen-

2774 J. Millward, Birmingham. Boilers. Dated September 9, 1868.

This consists in providing the upper ends of the heating tubes of vertical boilers with short extension pieces, forming prolongations of the tubes, and rising into the body of the water, above the crown plate of the firebox.

Inner or circulating tubes are provided at the upper ends of the extension pieces, with cloows or branches passing through the sides of the extension tubes, at some distance below the tops of the same, and a little above the tube or crown plate.—Patent completed.

2775 J. ADAMS and H. BARRET, Jersey. 7 Pump. Dated

2775 J. ADAMS and H. BARRET, Jersey, 2 ramp.

2785 J. Roberts of a barrel, furnished with a piston, having a spindlo valve at its lower end. The outer end of the piston rod is provided with an arm, connected to a rod, regulating bar, and hand lever. A pipe from the syrup reservoir is attached to the upper part of the barrel; the flow of the syrup is regulated by a stop cock and valve. The barrel is also provided with a valve, which is kept to its seat by a spring.—Patent completed.

to its seat by a spring.—Fatent completed.

2776 L. B. COVERT, New York. Ladders. Dated September 9, 1868.

The ladder is made with side pieces, grooved on the inner faces; these side pieces are united by cross pieces or steos; the steps may form a single front piece, or may be divided to form front and back portions, so that an extension ladder can slide in the grooved faces and move between the divided steps.—Patent abandoned.

2777 A. M. CLARK, Chancery-lane. Metallic packings. Dated September 9, 1868.

This consists in fitting segment pieces in the packing sockets of engines, and fitting in other pieces connected to springs to press the segments together. The springs are kept close by the ordinary gland bolts which pass through them.—Patent completed.

2778 A.M. CLARK, Chancery-lane. Opening envelopes. Dated September 9, 1868.

A wire is placed inside one edge of the envelope. On pulling either ent of the wire, the edge is severed, when the contents can be removed.—Patent completed.

2779 E. Wood, Bolton. Steam engines. Dated September 9, 1868.

The object of the first part of this is to work the exhaust valves independently, without any intervention or connection with the steam valve gear, by the employment of a second or separate eccentric or eccentrics, cam, or crank second or separate eccentric or eccentrics, cam or crank connecting rods, and wrist plate of the steam valves. The patentee places the condenser immediately under the cylinder. In this arrangement, the air pump has a situation underneath the condenser, being connected thereto by independent passages or thoroughfares, and with the foot and delivery valves of such condenser, which are connected to and placed on one side thereof, the exhaust thoroughfares of the cylinder being connected direct from above with the condenser.—Patent completed,

2780 A. V. Newton, Chancery-lane. Pumps. Dated September 9, 1868.

This consists of a hollow piston, having side openings in it, and double acting disc or puppet valves, carried by the piston and seating alternately, on or over apertures in the ends of the piston.—Patent completed.

2781 J. SHAND, Blackfriars. Boilers. Dated September

10. 1868. The boiler is constructed of an inner shell; the lower part of this shell is open at the bottom, where the firebars are placed. The upper part of the shell contains an arrangement of tubes; it is closed at top, except at the centre, where the chimney or funnel is attached. The shell is surrounded by an outer casing, continued up past the funnel.—Patent completed.

2782 G. Davis, Lincoln's Inn. Embossing horn. Dated

2732 G. Davis, Lincoln's Inn. Embossing horn. Dated September 10, 1868.

The apparatus is composed of a hydraulic pump, body or cylinder fixed in a wooden bench. It is terminated at its upper part by a bridge or spanner, and is closed at its lower part by a cover or valve facing, connected by flunges to the body of the pump. The cover is provided with three oridees or ports, arranged in the same manner as those of a steam engine—Patent completed.

2783 T. Bennett, Birmingham. Spoon and fork machinery. Dated September 10, 1868.

This consists in the employment of suitably shaped dies on rolls, whereby a hollow bead is made along the narrow part of the article, in order to give strength thereto.—Pintent completed.

Patent completed.

2784 A. A. Lejeune. Manchester. Printing fabric.
Dated September 10, 1868.

This consists in combining with the madder colours a certain proportion of a preparation of palm gum commonly called sago or tapicea; the quantity of this palm gum, or sago, or tapicea, depends upon the shade of colour to be printed. In producing red colours, the patentee takes twenty parts of an aluminous mordant, at from 10-leg, to 11-leg, of Beaume's hydrometer, and fifteen parts of the preparation of palm gum, which is to be mixed gradually with the mordant, and headed for from one quarter of an hour, at a temperature of about 53deg, of Beaume's thermometer. The solution must then be passed through a copper sieve and stirred with a hard brush; the solution is then completed by straining it through a cloth.—Patent completed.

2785 E. Padlety, Stafford. Anchors. Dated September 10,

2785 E. PADLEY, Stafford. Anchors. Dated September 10,

The patentee maker the stem or stalk of the anchor active than usual, and provides the stem with the ordinary ring through which the cable is passed. The arms of the anchor are made straighter than usual, and in place of the ordinary thicks at the ends of the arms, he ends are provided with enlargements. The flukes or holding parts of the anchor are arranged on opposite sides of the arms, instead of at the ends of the arms, as is usual.—Patent abandoned.

Patent abandoned.

2786 S. G. Archibald, Edinburgh. Reaping. Dated September 10, 1868.

This consists in machinery for cutting off the ears or heads of the crop. A comb projects downwards to within about 6in. of the ground. The teeth in the combare about 30 in. long and curved downwards, the points of which are sharp, and from 3in. to 4in. apart, but these spaces between them gradually decreases till sufficiently narrow to admit the straw, but not the ears or heads of the grain. Immediately below the comb, where the spaces are narrow, is placed a traversing knife, which cuts off the ears of the grain as they press between the comb. This comb being in front of a receptacle, the machine, by its onward movement merely, not only cuts off the ears, but presses them,

so that they fall over into the receptacle, from which they are gathered up and conveyed to a shed or granary.—Patent abandoned.

2787 W. M. NAUGHT, Rochdale. Furnaces. Dated Sep-

2787 W. M. MAUGHT, Rochdale. Furnaces. Dated September 10, 1868.

The patentee proposes to place the bars lengthways of the furnace; their inner ends are made to slide or move on a crank or rocking shaft, and their outer ends are arranged to move upon a cranked shaft, which leaves the ash pit clear. Motion is given to the rocking or cranked shaft, so as to slide or move all the bars slowly forward towards the fire bridge, carrying the fuel along with them.—Patent abandoned.

2788 J. MAYNES, Manchester. Looms. Dated Sep-

2783 J. MAYNES, Manchester. Looms. Dated September 10, 1863.

This consists in an arrangement of mechanism applied to the loom for changing the shuttles at one and the same end of the slay, namely, the shuttle carrying the broken or exhausted weft leaves the shuttle box, and the fresh weft is supplied to the same shuttle box instantaneously, and without reducing the speed of the loom, the essential advantages to this arrangement being that the outcoming shuttle drives the picker to the extreme or back end of the lathe or shuttle box, so as to be quite out of the way of the incoming shuttle, and this without the necessity of having some special mechanism for the purpose, and the outcoming shuttle is forced out of the shuttle box, without the aid of and quite independent of the picker.—Patent completed.

2789 A. B. IBBOTSON, Sheffield. Railway fastenings. Dated

2789 A. B. IBBOTSON, Sheffield. Railway fastenings. Dated September 10, 1868.

This invention has for its object the fishing or uniting of the ends of railway rails, by the employment of an elastic gripping metal clip which passes underneath the rails. The clip is secured in place by bolts and nuts.—Patent completed.

2790 C. H. J. MATTON, Regent-street. Stockings. Dated 2630 C. H. J. MATION, Acquarements.
September 10, 1863.
The papers connected with this invention are still with the law officers.—Patent abandoned.

2791 S. TRAGHEIM, Gray'S Inn-road. Cleansing fibres. Dated September 10, 1868.

The papers connected with this invention are still with the law officers.—Patent abandoned.

Dated September 10, 1822.

The papers connected with this invention are still with the law officers.—Patent abandoned.

2792 J. Challender, and P. B. Kitchin, Manchester. Fitting fog signals on rails. Dated September 10, 1863.

This consists in securing a vertical or inclined grooved channel, race, or slide to any convenient portion of the brake or guard's van that will form the terminal to a train beyond the himd wheels. The inclined slide is constructed so as to receive a fog or detonating signal, which, when placed in the orifice, at the top of the slide in the guard's van and released, will slide or pass downwards to the lower extremity of the groove, which is provided with a stop or hinge formed on the front portion or arm of a bell crank lever, which, when in its normal position, remains flush, or in a line with the slide, forming thereby a receiver for the signal, the space in front being open, so as to allow of the free movement or action of the lever. The opposite end of the bell crank lever is connected by a rod running parallel with the slide, with a handle in or on the guard's van, that forms the medium through which motion is given to the lever, and to the stop or finger holding or retaining the detonating signal; the fulcrum or centre upon which the retaining lever turns, admits of a slight lateral movement of such lever by means of a grooved wheel that comes into contact with the metals, and prevents the vibration or unsteadiness of the carriages, when running, from interfering with the true and respective position of the rail and signals relative to each other. The detonating signal is provided with spring clips or fasteners, which, when forced upon the rail, firmly close upon the upper flange of the metals, by which means such signals become permanently secured thereto, until exploded by the passage of a train over them.—Patent completed.

2793 J. Oliver and C. O. M'Allum, Newcastle-upon-Tyne. Utilizing alkaline salits.

2793 J. J. OLIVER and C.O. M'ALLUM, Newcastle-upon Utilizing alkaline salts. Dated September 10

The patentees state that if the soda mother liquors contain a large excess of chloride of sodium, they prefer to utilize the alkaline and neutral salts present as follows:

—They decompose the carbonate of soda present in the ash with sulphate of magnesia, in order to obtain hydrated carbonate of magnesia, precipitated, and sulphate of soda, in solution. A slight excess of carbonate of soda is employed, to insure the complete decomposition of the sulphate of magnesia, and to effect this, with some degree of certainty, they use hot solutions of carbonate of soda and sulphate of magnesia, at a temperature ranging from 160 leg. to 180deg. Fab. The soluble salts are separated from the insoluble carbonate of magnesia by the ordinary process of filtration; the supernatent liquor, containing the neutral saline salts, is evaporated to dryness, and treated with an equivalent quantity of sulphuric acid, to decompose the chloride of sodium present.—Patent completed.

2794 A. CRULE, Brussels. Pressing fuel. Dated Sep-The patentees state that if the soda mother liquor

2794 A. CRULE, Brussels. Pressing fuel. Dated September 10, 1863.

tember 10, 1868.
This consists in certain combinations of mechanism whereby pressure such as is required in various branches of manufacture, can be obtained in a simple and effectual manner. The frame of the machine consists of two upright portions, the top being semicircular, and pierced with a screw-threaded opening through which the main screw passes. Motion is given to the latter by a horizontal flywheel placed at its upper extremity, the same having several handles projecting downwards attached to it. The flywheel acts upon a smaller concentric wheel on which are one or more cams, which cams, when brought in contact with similar cams formed on the screw head, produce, by the action of a larger flywheel, a succession of shocks, giving a greater amount of pressure than can be obtained by a continuous action. The main screw is single threaded, the lower portion thereof being square, and passing through a socket which acts as a guide, and is held in position by two crosspieces. The bottom of the main screw is flyed to the compresser. At each corner of the bed of the press is a hole, through which holes small upright movable columns pass. The columns rest upon a crosspiece and carry the mould. A screw, to which motion is given by a small flywheel, raises the mould to allow the block of fuel or other article to be withdrawn, or lowers it, to be filled with fresh material. The mould may be divided into several compartments.—Patent completed. This consists in certain combinations of mechanism

2795 W. R. LAKE, Chancery-lane. Condensing apparatus Dated September 10, 1868.

This consists in the employment of a syphon, the long leg of which forms a waste pipe, and the short leg an injection pipe. Several long legs may be employed of aggregate capacity to that of the injection pipe. A pump may also be used to raise the injection water from the well. The condenser may be partitioned, so that the injection water is brought in direct contact with the steam, in order to heat it sufficiently before heing fed into the order to heat it sufficiently before being fed into the boiler .- Patent completed.

2796 A. C. HENDERSON, Charing Cross. Shoe straps or springs. Dated September 10, 1868.

This consists in making the side springs of boots of different coloured materials, that is to say, red inside and black outside, in order to distinguish the make of goods.

Patent completed.

2797 O. C. EVANS, Lambeth. Girders. Dated Septemer 11, 1868.

2797 O. C. EVANS, Lambeth. Girders. Dated September 11, 1868.

The patentee states that the invention consists, first, in forming and uniting in a chain alternately a square or oblong, with two half or connecting links (which are hook links) made of round, square, or flat bar metal. A hook, at each end of each half link, is formed at right angles with the bar, in such manner that, when inserted from underneath the end bar of the open link, and the hook from the inside will rest on the side bar of the open link, and the end bar of the open link on the bar of the half link, if both are brought within the same curve or plane.—Patent abandoned.

2798 B. Dobson, Bolton, Wood cutting, Dated Septem-

2798 B. DOBSON, HOILOR. Wood cutting. Dated September 11, 1868.

This consists of a combination and arrangement of machinery for effecting the various operations required to saw, plane, and sand-paper mule carrriages, and other articles, which operations can be performed, either separately or successively, and simultaneously, in the same machine.—Patent completed.

and simultaneously, in the same machine.—Patent completed.

2799 W. Thompson, Dublin. Sifting, cutting, and mixing tea. Dated September 11, 1868.
Upon the top of the framing of the tea mixing apparatus is fixed the tea cutting apparatus, composed of a horizontal cylindrical casing made slightly tapering towards one end, in which is fitted a rotating drum of a corresponding apering form, carried by a central spindle which passes through the casing, and is provided at one end either with a crank handle. On the surface of the drum are fixed or formed a number of cutting edges or blades running along the whole length of the drum, and on the sides of the casing are fixed or formed other cutting edges or blades, also running the entire length of the casing, which latter blades are, by preference, secured in a removable manner by means of screws to lugs on the outside of the casing, and are made to pass through slits formed on the latter, so as to be readily removable when requiring to be sharpened; they may, however, also be formed or fixed permanently on the inner surface of the casing.—Patent abandoned. abandoned.

abandoned.

2800 B. D. Godfrey, Chancery-lane. Securing soles on boots. Dated September 11, 1863.

The patentee employs sprigs, which are formed with screw threads, but which, instead of being inserted by turning or screwing them in, are driven into the sole, like an ordinary nail or peg, two or more threads being formed on the sprig, to give the screw a quick pitch, so that the act of driving in the sprigs causes their rotation in the leather.—Patent abandoned.

leather.—Patent abandoned.

2801 J. Hudden, Stockport. Filtering casks. Dated September 11, 1868.

This consists in supporting the barrel on a swivel stand, and connecting the hind portion of the barrel, by means of a hook and chain, to a quadrant, secured to or forming the end of a lever, which is supported on a shaft, rod, or pivot, that forms the fulcrum of such lever, the projecting end, on the opposite side of the fulcrum, being supplied with an adjustable counterpoise.—Patent abandoned.

with an adjustable counterpoise.—Patent abandoned.

2802 J. Bullough, Lancaster. Warping machines.
Dated September 11, 1863.
This consists in a certain mechanical arrangement
whereby a warper is relieved from the necessity of turning the yarn beam by hand, to take up the slack or
overun of the bobbins, before starting the machine after
a stoppage. At the end of the warp drum shaft there is
a friction motion or clutch box, which is brought into
gear by the pressure of the warper's foot on a treddle,
running along the front of the cylinder and near to the
floor. This treddle is held by two arms, one at each side
of the drum, which are fastened to a rod, each end of
which rests in a bearing fixed to each side of the machine.
The machine having stopped, the swing or drop rollers
descends and takes up the overun of the bobbins.—Patent
abandoned.

2803 E. T. HUGHES, Chancery-lane. Annealing wire. Dated September 11, 1868.

This relates to annealing gauze wire used in the manufacture of paper, and consists in causing the wire to pass over a heated cylinder, by which means it is more evenly and thoroughy annealed.—Patent completed.

# APPLICATIONS FOR LETTERS PATENT.

PATENT.

Dated March 15, 1869.

785 J. Henderson and T. Brown, Kirkcaldy, Fifeshire. Improvements in the construction of water cocks or valves.

786 W. A. Martin. Union-street. Southwark, Surrey. New or improved apparatus for diffusing the heat and promoting the generation of steam in steam boilers.

787 E. Sands, Manchester. A new mode of producing motive power by continuous rotary motion.

788 J. C. Shaw, Patricroft, near Manchester. An improved traverse card grinder.

789 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in healds and heald frames for weaving, and in the manufacture of the said healds.

790 H. D. Rawlings, Nassau-street, Portland-place. Improvements in apparatus employed in filling bottles or other receivers with aerated liquids.

791 J. G. Jennings, l'alace-road, Lambeth. Improvements in apparatus for preparing sewage for irrigating land.

792 G. P. Evelyn, Army and Navy Club, Pall Mall. Improvements in the construction of the sails, yards, and rigging of ships or vessels.
793 J. R. Cooper, Birmingham, Improvements in

rigging of ships or vessels.
793 J. R. Cooper, Birmingham. Improvements in breech-loading firearms.
794 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in steam vessels for ocean and river navigation.
795 W. R. Lake, Southampton-buildings, Chancery-lane. An improved multiple drilling machine.
Dated March 16, 1869.
796 J. Taylor, R. and J. Ingram, and J. Sharplis, Crawshaw Booth, Lancashire. Improvements in carding engines of the class in which the doffing cylinder is divided into spaces, and a novel method of testing and utilizing the slivers from the same.
797 W. A. Lyttle, The Grove, Hammersmith. Improvements in the means and apparatus employed for sustaining and insulating electro-telegraphic overland line wires.
798 W. M'Adam and S. Schuman, Glasgow. Improvements in the means and other frangible articles.
799 O. Whittaker and H. and I. Wallwork, Hurst, near Ashton-under-Line. Improvements in the construction of saddles and hangers and top and bottom bearings for shafting, and rollers used in connection with machinery for preparing and spinning cotton and other fibrous substances.
800 F. Render, Manchester. Improvements applicable

800 F. Render, Manchester. Improvements applicable the transport of minerals and other merchandize upon

railways.
801 W. Campion, Nottingham. Improvements in sew

ing 1. machines.

2 W. Robertson, Queen's Chambers, Market-street, nehester. Improvements in self-acting mules and Manchester.

Manchester. Improvements in self-acting mules and twiners.

803 L. Engel, Mumford-court, Milk-street, City. Improvements in umbrellas, sunshades, and parasols.

804 J. L. Norton, Belle Sauvage-yard, Ludgate-hill, City. Improvements in looms for weaving.

805 W. and C. S. Catt, Ipswich. Improvements in the joints of carriage shafts, and in connecting splinter bars to carriages.

joints of carriage shatts, and in connecting spinion base to carriages.

806 E. Roper, Garrick-street, Middlesex, and G. Shaw, Penkhull, New-road, Stoke-upon-Trent. Improvements in the production or preparation of printing blocks, plates, and cylinders, with surfaces in relief and intaglio.

and cylinders, with surfaces in relief and intaglio.

Dated March 17, 1869.

807 J. James, Princes-street, Stamford-street, Lambeth. Improved apparatus for compressing powders into pellets. 808 E. W. P. Gibbs, Westbourne Park-orescent, Harrow-road, Paddington. The improvement in the method of propulsion of vehicles commonly denominated velocipedes, by the application of levers of unequal arms, acting on cranks fixed in the axle of the rear wheel or wheels, and on a fixed or movable fulcrum.

809 B. Latham, Westminster Chambers, Victoria-street. Improvements in the means and machinery or appliances for filtering and straining liquids, especially applicable for straining sewage.

for straining sewage.

810 T. Rickett, Birmingham. Improvements in velocipedes and other wheel vehicles.

811 J. J. G. Damitte, J. M. Agnellett, and H. D. Dubois, Paris. Improvements in the manufacture of pulp.

812 H. Claughton, Dumbarton. Improvements in screw propellers.

812 H. Claughton, Dumbarton. Improvements in screw propellers.
813 J. Heywood and J. Wild, Tonge, Lancashire, and F. Murphy, Middleton, Lancashire. Improved tapes for renetian window blinds, for ribbons, hatbands, and similar articles, and for improved looms and apparatus for weaving them.
814 M. Rourke, Manchester. Improved combinations of textile fabrics and paper (for oil and tar cloths, floor cloths, tarpauling, table-covers, and similar articles, and the mode of manufacturing the same.
815 J. Carter, Nottingham. The manufacture or production of chemical night soil closets, and for other similar purposes.

duction of chemical night soil closets, and for other similar purposes.

816 H. Starr, Moorgate-street, City. {An improved safety hook for harness and other purposes.

817 F. Gillham, Liverpool. Improvements applicable to hats and other like coverings for the head.

818 J. H. Bennett, Leith, Mid Lothian. Improvements in steam engines and boilers.

819 C. F. Claus, Middlesbro-on-Tees. Improvements in the manufacture of carbonate of potash and the recovery of certain products evolved therein.

of certain products evolved therein.

Dated March 18, 1869.

\$20 J. Ramsbottom, Crewe, Chester. An improved mode of ventilating railway tunnels.

\$21 T. Martin, Seafield House, Formby, Lancashire. Improvements in the means for supplying ammunition and other objects to troops under action, and in cars or vehicles employed for that purpose, also improvements in such ammunition and in the mode of packing the same.

\$22 G. R. Mather, Wellinborough, Northamptonshire. Improvements in means or apparatus for cutting or giving form to wood.

-823 J. C. Ramsden, Bradford, Timprovements in looms rweaving.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be such, payable to ROBERISON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

# PROVISIONAL PROTECTION FOR SIX MONTHS Has been granted upon Specifications bearing the following numbers:—

THE

# MECHANICS' MAGAZINE.

LONDON: FRIDAY, APRIL 2, 1869.

# INSTITUTION OF NAVAL ARCHITECTS.

THE first paper read at the meetings of this Institution, was one by Mr. William Institution, was one by Mr. William Fairbairn, "On the Law of Resistance of Armour Plates." As early as the year 1835, Mr. Fairbairn had satisfied himself that iron was the proper material for the construction of ships, not only for the merchant service but also for the navy. In accordance with this conclusion, Mr. Fairbairn endeavoured to impress upon the Government of that day the necessity of building iron men-of-war, and offered his services in the superintendence of experiments to determine the effect of shot upon targets built to represent the sides of iron ships. The Government, however, fought shy of the new material, and limited its use to vessels built for the mail and packet service. Targets were built, and experiments conducted in the presence of the Lords of the Admiralty, from which the authorities at Whitehall concluded that iron was not a suitable material for the construction of vessels as ships of war. For twenty years, the Admiralty remained deaf to the calls of the Admirately remained dear to the cans of iron, until armour plates were suggested by the Emperor of the French, as a means of defence for ships of war. This led to the building of "La Gloire." The English followed suit with the "Warrior" and "Black Prince." Soon after this time, the Iron Plate Committee was appointed, and for several years there was a constant series of experiments to test the rival powers of guns and plates. In a few years, the 41-inch plates had added to their thickness an additional 10 in. of solid iron, while the guns had grown from 68-pounders to 600-pounders, and who knows but that they will still grow, and that we may ere long be deafened with "the roar of a 40,000-pounder."

While these experiments were being carried on, it was thought advisable that a second series of experiments on the same plates should be conducted. They were subjected to statical pressure, with a view to determine the law of resistance, and to establish formulæ for the guidance of the artillerist and the engineer. Experiments were made on the shearing, tension, and compression of three iron plates and one steel. The result showed that the tenacity, as indicated by the ultimate elongation, increased directly with the increase in the thickness of the plate. The compression did not change appreciably with the thickness. With regard to the third and more important point, the regard to the third and more important point, the riper and purposing a papelogy was point, shearing and punching, an analogy was supposed to exist between the resistance of iron plates to shot, and their resistance to statical pressure. It was desired to ascertain the law of the resistance to punching. These experiments fully established the fact that the resistance of armour plates to punching varies directly as the product of the diameter of the directly as the product of the diameter of the punch and the thickness of the plate, or the depth of penetration, and this regardless of the form of the punch. The indentation, how-ever, of a round-ended punch, was more than three times as great as that of a flat-ended one; hence we deduce that the work expended in punching with a flat-ended punch is very much less than with a round. This is a point well worthy of attention, though, of course, it must not be assumed, without trial, that the metal in the neighbourhood of the punched hole is equally strong in both cases. In applying the formulæ deduced from these

conclusion that the action of the shot is approximately the same as that of the punch. A large part, however, of the work accumulated in a shot is wasted, through the breaking up of the shot itself. Even with hard flat-ended steel shot, which are very effective for perforation, more than half the accumulated work is lost or expended uselessly. This waste Mr. Fairbairn puts down to one or more of the following causes:-1, distortion of the shot; 2, the size of the perforation being much greater than that of the shot; 3, injuries to the plate other than per-foration; 4, the oscillation or recoil of the plate when struck; 5, want of directness of impact. The work expended in these ways need not necessarily be wasted. Its expen-diture in these ways only lessens the balance upon which we may draw for the mere per-foration of the plate. Mr. Fairbairn hopes in another year to be able to give the result of a course of experiments on the relative power of resistance to perforation of solid plates, and plates built up of several thick-

The next two papers were both on the same subject, "Floating Docks;" the first was read by Mr. George B. Rennie, and the second by Mr. Charles H. Wigram.

Mr. Rennie's paper consisted of a description and a calculation of the stability of the iron floating dock at Carthagena. It is a huge rectangular box, without top or ends, the walls and bottom being hellow and the walls and bottom being hollow and divided into chambers. The vessel to be divided into chambers. docked is run in at one of the open ends, the hollow chambers are then emptied, and the vessel is thus raised high and dry out of the water. The vessel is shored in the manner usually adopted in an ordinary graving dock. A Spanish frigate drawing 27 t. of water has been raised by this dock, and the ironclad "Numancia," of 5,600 tons weight, remained supported in the dock for eighty days, without any damage either to the ship or the dock. With this ironclad on board, the dock drew 111ft. of water. Mr. Rennie advocated the rectangular form of floating dock in preference to the U-shaped docks, like the one which has been built for Bermuda. The advantages are simplicity of construction, small amount of material for required strength, smallness of cost, simplicity of working, and safety. Its chief disadvantage is that the rectangular form is not at all suitable for a voyage, but, nevertheless, docks of this shape have been towed for great distances. A noteworthy example is the Alexandria dock, which was A noteworthy built in the south of France.

Mr. Wigram's paper was a short one on a dock which had been proposed for the Austrian Government. It was designed to dock the unfortunate ship the "Radetzki" (lately blown up), which was of 174ft. draught. The accommodation at the Austrian ports in the Adriatic is not equal to the requirements of a vessel of this size. The "Radetzki" was to be docked in deep water, and then, after pumping out the water from the chambers, the dock and vessel were to be run into shallower water alongside the arsenal. Here is an instance of a case where a floating dock is not only useful but absolutely necessary. At Bermuda, too, where the rock is so porous that it is impossible to make water-tight masonry, a dock of this kind, if any, must be resorted to. Though not so any, must be resorted to. sanguine as some of the gentlemen who spoke on this subject, and who thought that, before long, every fleet would be accompanied by its floating dock, we yet regard with favour a method of supplying docks to ports which must otherwise have been dockless, and, in many cases, of saving great expense in masonry.

Iron Works, Chelsea. It is by Mr. Woolner, the well-known artist, to whom too great praise cannot be given for the masterly manner in which he has treated the subject. He has represented Lord Palmerston in the act of addressing the House of Commons, and has succeeded in enduing the figure with a life-like energy of expression and dignity. The statue is intended to be placed in Palaceyard; it is 7ft. in height, and contains about 25cwt. of bronze metal. Of this quantity nearly 10cwt. was obtained from the statue of Sir Robert Peel, which has lately been removed from Palace-yard and broken up. The mould was commenced in January last, and the term of the contract expires with the present month. The metal was run on the 1th ult., and the statue is now on the eve of completion. It is certainly a faithful and masterly representation of the illustrious

The inspection of this casting affords us an opportunity to say a few words upon the subject of statue founding generally. In the first place, it is a great compliment to the Messrs. Holbrook, for unless a firm has successfully carried out some of these large works of art they have little or no chance of obtaining the contract from the sculptor. And this is very reasonable, inasmuch as the And this is very reasonable, masmuch as the whole success of a sculptor may depend on his first figure being well and faithfully carried out according to his design. One bad cast may seriously injure an artist's reputation. For this reason, artists are particularly correct to send their works to the ticularly careful to send their works to the firms best known, and thus it has happened that there has always been a tendency for this special branch of business to fall in a few hands only. Hence, Messrs. Elkington, of Birmingham, have lately held the highest reputation, and have done a very large business with but little fear of competition. There is, however, a great disadvantage in having these castings made out of London, where the leading sculptors are located. The cast has always to be chased before it can be presented the public, and this must always be done under the supervision of the sculptor. When the cast is made in London, the inconvenience of sending the figure back to the artist's studio is avoided.

We will now describe generally the method of procedure, by which the cast is produced. The first point is to form the box or cast-iron framework, in which the cast is to be made. The sides and ends are, for a figure such as Lord Palmerston's, about 11 in. thick, and these are braced across by diaphragm plates, to prevent any springing. Into this bed the figure is laid, and, to prevent any movement, ordinary moulding sand is rammed tightly round it up to the edge of the box. The edge of the box is as nearly as possible the greatest diameter of the figure. To the portion ex-posed above the box, plastic clay loam is applied. The art of the moulder is required to arrange his clay, so that he may be able to remove it from the figure. To this end, he arranges the clay in separate bricks (so to speak), and when the model is removed, he builds these up together again. As the shape of each piece of clay is formed by its own pressure against its neighbour, the pieces fit exactly. Each piece of clay being applied, red hot irons are laid on it to force it into its position, and to prevent it cementing with its neighbour.

A second frame is then placed over the figure on the top of the lower one, and sand is rammed in to prevent any movement. The whole mass is then turned over. The first box, which is now at the top, is taken off, and clay applied as before. After the whole figure has been prepared in this way, and the core is formed and placed in its position, the the metal in the neighbourhood of the punched hole is equally strong in both cases.

In applying the formulæ deduced from these experiments to the results of experiments at Shoeburyness, Mr. Fairbairn comes to the Messrs. Holbrook and Co., of the Manor poured in, the steam given off has driven the molten metal up the channels, and a frightful catastrophe has been the result. Much of the success of the cast depends on the metal being run in at the same tempera-ture throughout the figure. To insure this, a large tank is formed above the boxes, with plugs attached to a lever. On the lever being raised, the metal rushes down into the mould, and the cast is the work of a few seconds only. The thickness of metal in the statue of Lord Palmerston is about 3-8ths of an inch. The number of inlets for the metal to enter

the moulds was fifty-two.

One of the chief difficulties in statue casting is the necessity for making the cast in one piece. It is not, however, unusual to cast these figures in separate pieces, but then the delicacy of the artist's touch is lost in the separate manipulation of the parts, and the result frequently is that the reproduction, after a brief existence, is consigned to the hammer. Another cause of failure often is the want of adequate lifting power. to the size and weight of the mould enclosed in its iron framework (stayed and braced to prevent the slightest displacement while the prevent the slightest displacement while the mould is being formed), great lifting power is always necessary. The mould of the Palmerston statue weighed about 11 tons. Every facility for producing a successful result is found in the foundry department at Messrs. Holbrook's works. The building is spanned by two large wrought-iron travellers, each capable of carrying 20 tons; and with these and other convenient appliances at his disposal, the contractor can confidently at his disposal, the contractor can confidently anticipate successful results. A colossal figure, for the Canadian colonies, to be cast in Florentine bronze, is rapidly approaching completion at Messrs. Holbrook's works, and we hope in a few weeks to record its successful casting. The artist in this case is Mr. Wood.

# PRESERVED MEAT.

DR. LETHEBY, in opening his fourth Cantor Lecture on food, delivered before the Society of Arts at the close of last year, observes:—"It requires no argument to show that the preservation of food is a matter of great public importance; for it not only enables us to provide against actual want in periods of unusual scarcity, but it also affords the means of equalizing the dis-tribution of food at all times, so that the excess of one country may be used in supply-ing the deficiency of another." The waste of meatin Canada, Australia, Tasmania, the Cape of Good Hope, South America, and other parts, is a fact too well known and too much regretted to be disputed, and for years the great question has been how to utilize the enormous quantity of food annually lost. In other words, the great problem to be solved was how good meat at the antipodes might be made available for home use at a low price, instead of the carcases being slaughtered merely for their fat, skin, and The solution of this problem has been attempted in various ways, which may be resolved into three distinct classes of treatment. These consist in preservation of substances by drying them, which is of very ancient date; preservation by excluding atmospheric air, which is also of considerable atmospheric air, which is also of considerable antiquity; and preservation by the application of cold. There have been many processes devised at various times for carrying and the several methods of treatment. It is not, however, our present purpose to describe these, for so many have proved failures. We shall therefore content ourselves by observing shall therefore content ourselves by observing that as the object is to preserve meat in a fresh state, with all its nutritious properties intact, the process of drying does not wholly commend itself, inasmuch as it involves the use of salt or some other antiseptic, and the product is salt provisions. The application of freezing which was thought a properties.

since, to have proved a success, has practi-cally failed, and we cannot learn of its adop-

As the deprivation of heat appears to have been unsuccessful, and the deprivation of moisture only gives us salt food, we must turn to the deprivation of oxygen as a means of obtaining really wholesome and nutritious food. This, in fact, is the process now generally employed by those who are engaged in the preservation of food. It is carried out in various ways—either by filling up the vessel with a heated substance; by destroying the oxygen of the air in the vessel by heating the substance in it; by exhausting the air from the vessel containing it; or by driving out the air by means of steem. This last is out the air by means of steam. This last is the method most commonly employed, and the method most commonly employed, and with invariable success. As an illustration of this system, we propose to describe the preservation of food as carried on by Messrs. John McCall and Co., at their works at Ramornie, New South Wales, and at Maribyrnong, Victoria, as well as at their London establishment, 137, Houndsditch, the latter of which we recently visited. We may premise that the two antipodeal establishments are that the two antipodeal establishments are known as the Australian Meat Company and the Melbourne Meat Preserving Company. They were formed for the purpose of preserv ing beef and mutton, and shipping it to this country for domestic use, as well as for that of the naval and mercantile marine as a substitute for salt provisions. The meat is stitute for salt provisions. The meat is imported in tin canisters containing 2lb., 4lb., and 6lb. each. Messrs. McCall and Co. have for many years preserved English provisions by the same process used in the colonies. The Australian Meat Company was formed in 1866, when Messrs. McCall were induced by the high price of meat in this country to propose to gentlemen interested in the vast cattle and sheep runs of Australia the erection of a manufactory for preserving meat in the colony. Those gentlemen entered into the project with spirit, and a manufactory was erected at Ramornie, on the Clarence River, New South Wales. During 1867 and 1868, 1,164,970lb. of preserved meat (principally beef) were shipped to this country. The attempts to bring Australian meat in a fresh state to this country have been many, but the Australian Meat were induced by the high price of meat in have been many, but the Australian Meat Company deserves the honour of being the first to bring large shipments, and, from their excellence, to find a ready sale for them. Indeed, the plan of preservation adopted by this company (viz., that of removing the air from the meat in the process of steaming), is the only successful plan by which Australian meat perfectly fresh, free from salting or smoking, has been imported. The Melbourne Meat Company commenced operations more recently, but with the same mode of preserving. Our statement with regard to the complete success of Mr. McCall's plan of preservation is borne out by the Food Committee of the Society of Arts, who reported, on June 26, 1867, as follows:—"They (the committee) have examined various plans, but the only one by which they have as yet found that unsalted meat in a solid eatable condition has been largely imported, is that followed by 'The Australian Meat Company.' The process is that long used for preserved provisions. The beef arrives in tins, from which the air has been excluded, and, from the heat employed, is sufficiently cooked to be eaten without further dressing. It may, however, be stewed and served hot, if preferred." Our own experience of the provisions preserved by this company is that they are a palatable and nutritious food, and we recommend those who have not yet tried the Australian beef and mutton, at once to make the experiment.

The Melbourne establishment at Maribyrnong is a well-organized factory, complete 90ft. by 30ft., where, on its arrival from the slaughter-house, the meat is cut up into joints, and the bones and surplus fat removed, previously to its being disposed of in the kitchen immediately adjoining. Over this room is another of the same dimensions, termed the "tin shop," capable of accommodating forty tinsmiths. About half that number of men are generally engaged in constructing tin canisters at the rate of about 12,000 per week. Chimneys are provided over each man's fire pot, to carry off the fumes of the charcoal, which are frequently found to be very injurious to the health of the workmen. Adjoining this is the machinery room, where various machines are in full operation for cutting up, rolling, stamping, and otherwise preparing the sheets of tin for the tinsmiths to solder together. Contiguous to this room and to the butcher's department below, is a spacious and lofty kitchen where the meat is submitted to various processes of cooking. When ready, the cooked meat is packed into the canisters and carried to the preserving department overhead by means of a lift. In this room the tins are soldered down completely airtight, with the exception of a small hole in the lid, by means of which the air is expelled. They are then placed in baths of a solution of chloride of calcium, which is raised to a very high degree of temperature by a steam coil. In these baths the tins remain from two to three hours, according to their size and the nature of their contents. From thence they are lowered into tanks of cold water in a room beneath, called the cooling room, it being desirable to cool the canisters as quickly as possible after preservation, to prevent the meat being over cooked, which is always the case when the canister is allowed to cool of itself. At the extremity of this room is another called the testing room. This is an apartment built of blue stone, and heated by the flues from the boilers being made to traverse it. An artificial temperature equal to that of the tropics can thus be obtained, which serves to discover any flaw in the tins which might have escaped previous observation, or any error made during the preserving process, so that the canisters which have passed this ordeal may with perfect safety be guaranteed to stand any climate in the world. Below this room are placed two large boilers in which steam is generated, and which serve also to boil the vats, placed in a room con-tiguous wherein the fat is converted into tallow. Alongside of these boilers is a steam engine of 16-horse power, used for sawing the wood with which to construct packing cases, for grinding bones, and for other purposes. Adjoining are capacious store rooms in which the tins are painted, labelled, and packed ready for exportation.

Similar to this establishment, although, of course, on a less extensive scale, is that of Messrs. McCall's, in Houndsditch. Here are all the necessary arrangements for preserving various articles of food, and manufacturing the tin cases for their storeage. Here, on our visit, raw food was being put into canisters and soldered down, a pinhole aperture being left in the lid. The canister is subjected to the heat of the chloride of calcium bath, until the contents are about two-thirds cooked; then, while the steam is blowing freely out, the pinhole is cleverly sealed with solder. Meat properly preserved in this manner will been for years. keep for years. For twenty-five, thirty, and even forty-four years has meat been perfectly preserved after similar treatment to the above, and thus we have a ready means of "providing against actual want in periods of unusual scarcity," and of equalizing the dis-tribution of food, so that the excess of one country may supply the deficiency of another.
This is of course of the highest importance in an economic point of view, in which respect the question of supply wears a threefold aspect, commend itself, inasmuch as it involves the use of salt or some other antiseptic, and the product is salt provisions. The application of freezing, which was thought, a year or two by the ground floor is a well-ventilated room, ing the supply of meat for domestic purposes,

we may observe that the Ramornie beef is sold retail at 7d. and the Melbourne mutton at feld. per lb. As the meat is without bone, this is equal to buying ordinary butcher's meat at 5d. to 5\flackddot do per lb. Next, the interests of the sailors in the Royal navy are concerned. According to a letter from H.R.H. the Duke of Edinburgh, the cost of preserved meat manufactured by the Admiralty is 11d. or 1s. per lb., and from its high price is only given to the men occasionally. The Australian meat can be supplied at a much lower price, and if preserved fresh meat were served out in turn with salt meat, both the British navy and the British taxpayer would benefit, while the vast number of cattle slaughtered at the Government yards would go to increase the meat supply of this country. Lastly, the mercantile marine is very much affected in the introduction of Australian meat as a preventive of scurvy among the men. The Board of Trade issued last year to all the local marine boards a proposed scale of diet for British seamen, in which preserved fresh meat and vegetables were included as preventives of this disease. The price of Australian meat being less than that of salt provisions must surely induce shipowners to make it a regular article of diet.

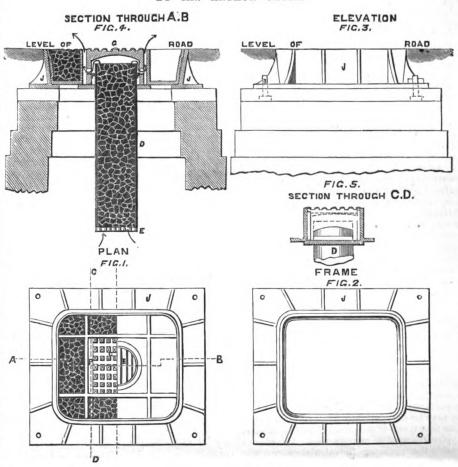

We have devoted some space to the consideration of the question of preserved fresh meat, because it is of importance as solving a meat, because it is of importance as solving a problem which has long troubled some of our colonists. The introduction of Australian meat on a large scale will greatly conduce to the better living of our working population, and better health of the Royal navy and mercantile marine. It is already influencing men's minds in various quarters. The recent opening of a depôt at Birming-ham has caused the butchers there to lower their prices, whilst attention having been drawn in the House of Commons to the matter of preserved meats for the navy, the Government has advertised for tenders for the supply of this desirable food. Instead of costing the country 11d. and 1s. per lb., our navy can be provisioned at 6d. or 7d. The meat has already been tried in the Royal navy, and very satisfactory reports have been received by the Admiralty, so that our sailors may now expect to be more frequently indulged with an agreeable and wholesome alternative to salt provisions at sea. Private shipowners are endeavouring to introduce it amongst their crews, but Jack is found to have suspicions that all is not quite fair and aboveboard. He thinks that because it is cheap his owner only wants to save a few pounds, not believing that his health is really of more value than the few pounds which may, per-haps, be saved on the run. However, Jack's scruples will, doubtless, yield when he finds his palate gratified and his health improved, so that we do not doubt but that in time the value of preserved meat will be fully recognized.

## SEWER VENTILATION.

VARIOUS have been the means proposed for safely getting rid of what may be termed the secondary contents of sewers. one time it was considered that, provided a sewer had a good fall, and that there was a constant and sufficient supply of water to effect the flushing, nothing more was required. In a word, if the first contents were thoroughly removed, there was nothing to fear. Experience, and, unfortunately, dearly earned experience, has proved that there is a great deal more to be dear. deal more to be done. Sanitary engineers are well aware that only half the task is accomplished when the sewage is conveyed away. There yet remains what we have called the secondary contents, which are in some degree the products of the first, and consist of the contaminated and vitiated gases existing throughout the subterranean conduit. There is not the slightest difficulty in removing

# SEWER VENTILATOR.

BY MR. ARTHUR JACOB.

these from the sewers. They will get out | fast enough of themselves, through everyhole and grating, that may place the interior of the sewer in communication with the outer The problem is not to let them atmosphere. out in this condition, but either to lead them away out of the reach of human nostrils and human throats, or to subject them to some process of purification before they are permitted to leave the sewer, and escape into the With the view of accomplishing the result desired by the former method, it has been proposed to transport them into large chimneys, and there consume them by fire. Some contended that the rain water down-pipes should be utilized for the purpose, but the serious objection against such a measure is, that frequently garret and upper a measure is, that frequently garret and upper storey windows are placed in very close con-tiguity to their mouths. In dealing with the disposal of sewage gases, the preferable plan appears to be to deodorize them previously to allowing them to pass from the sewers into the air.

A new design for a sewer ventilator has been recently patented by Mr. Arthur Jacob, C.E., which presents some features differing from those belonging to the ordinary methods in use. In fig. 1 is represented a plan, one half of which shows the cover C, placed over the upper part of the cylinder D (see figs. 1, 4, and 5), and the other, the grating E, fixed at the lower end of the cylinder, at the junction of the manhole with the sewer. The cylinder D is filled with charcoal (see fig. 4), and the sewage gases gain admittance to it through the grating E, already alluded to, as shown by the arrows. By virtue of their inferior specific gravity, they rise up through the interstices of the loosely-packed charcoal, and make their exit into the air by means of the slits or apertures P, placed for that purpose in the sides of the cover. One advantage of the substitution of the cylinder, filled with charcoal in the manner described, for the shallow trays hitherto employed, is

that a much larger surface of the deodorizing charcoal is available for effecting the purification of the gases, and, also, that as the operation is slower and more deliberate, it is accomplished with greater efficiency. Manifestly, the first point that a ventilator of this nature should ensure is that the deodorization of the gases should be thoroughly and substantially performed. If the gases, after undergoing the purifying action of the deodorant, still retain any offensive or injurious qualities, the whole apparatus is a failure, and a cause of needless and useless expense to the ratepayers. To keep every ventilator in which this principle is carried out in proper working order, the contents of the trays or cylinder, as in the present example, must be changed at intervals. The accomplishment of this, in a simple and rapid manner, is one of the chief meritorious features of Mr. Jacob's patent. Nothing more is required than for one man to go round with a cart containing a supply of fresh charcoal, to take off the cap C, lift up the cylinder, empty out the contents, replace them with a new charge, and drop the cylinder into its place again. A few minutes will suffice to accomplish what takes nearly an hour to get done under the ordinary plan in practice.

An elevation of the frame J is shown in fig. 3, with the holding down bolts and cottars, and fig. 5 represents a cross section through the cover, taken along the line C D, on the plan in fig. 1. In constructing the manhole for this ventilator, there is less excavation and brickwork required than in any other, as there are no side chambers needed. As a set-off against this saving, there is the cost of the cylinder, which is of galvanized iron, which would be in excess of the common trays. If a balance be struck, there will be no appreciable difference of cost between Mr. Jacob's ventilator and others in ordinary use. From the simplicity of the arrangement of all the parts, and the ready manner in which the charcoal can be removed and replaced, we

consider that the apparatus is calculated to be of great service to our cities and towns, and will tend to relieve local boards from one of the difficulties with which they have had to contend for some years. The recent sanitary regulations, and the summary manner with which they are enforced, have pressed so heavily upon all local corporate bodies, that they ought to hail with delight any invention or improvement that has a tendency to practically solve the question of the disposal of sewage and the ventilation of sewers.

#### NOTICES OF BOOKS.

THE manufacture of worsteds and carded varns is now one of the leading interests of America, so that a trustworthy practical treatise upon the subject forms an important adjunct to the manufacture. Such a treatise\* has recently reached us from across the Atlantic. It is a translation of M. Leroux's work, and comprises practical mechanics, with rules and calculations applied to spinning, sorting, cleansing, and scouring wools. It also describes the English and wools. It also describes the English and French methods of combing, drawing, and spinning worsteds, and manufacturing corded We have referred to the importance of this branch of industry in America. In support of this, we may observe that, even by the census of 1860, it appears there were then in the United Kingdom 1,263 woollen and worsted mills, and 712 wool carding establishments. In 1864, the total productions of woollens was estimated at 120,000,000 dollars. This industry has of late received a remarkable impulse, and is now of the first importance in the States. The volume before us may be divided into five principal parts. The first treats of the principles of mechanics applied to woollen manufacture. In order to enable the operator to calculate accurately the velocities required by the various pieces of his machinery, vary the pressures of the top rollers, according to the staple of the wool and the varn to be manufactured. Secondly, we have the properties and nature of the principal sorts of wool found in the market considered, as well as the processes for sampling, washing, and scouring any kind of wool, preparatory to its treatment, whether for combed or corded yarns. Next, we have a description of the French method of making worsteds (combed yarns), which differs from the English mode of operating, especially in the drawing processes, where the sliver is never twisted, but is only drawn out, at the same time that the fibres are constantly kept in a state of parallelism, by passing over a circular comb. Fourthly, we have described the English method of making worsteds, where the slivers are twisted at each operation. And, finally, the work treats of the manufacture of corded wool, which is about the same in both countries, except at the last stage of the operation, when peculiar styles of throstle frames are used instead of the mule. The book also contains numerous tables, which are the result of long experience, and will be found very use-The decimal system of weight and measures has been-judiciously we thinkpreserved, and at the end of the volume are tables and ready made calculations, by which the quantities in the text may easily be converted into English equivalents. In order that the volume may be rendered as complete as possible, such facts are added in connection with the Paris Exhibition of 1867 as throw light upon the latest and most important improvement in woollen machinery, manipulation and fabrics. The work is illustrated by twelve large plates, and, altogether, forms an important adjunct to the branch of

industry it illustrates. The translators deserve credit for a clear, methodical and faithful translation.

The question of valve gears and motions has been sufficiently discussed of late, in various ways by practical men, as to call for a third edition of Dr. Zeuner's treatise on the subject. This treatise\* has been revised and enlarged by its able translator, Mr. Moritz Müller, and now comes before the public with the results of all the recent investigations into the matter upon which it The first part of the work is devoted treats. to valve gears with one slide-valve, and embraces a consideration of simple valve gear with fixed expansion, and reversing motions with variable expansion. In the second part, the author enters upon the consideration of valve motions with two valves. The various link and valve motions are truly described, special attention being given to the locomotive link motion. A thorough instruction in the study of the action of valve motions is especially welcome to the designer, and he will meet with it in Dr. Zeuner's treatise.

Mr. Timbs is again before us with his "Year Book of Facts," t in which he gives a summary of the most important improve-ments and discoveries in science and art that have been made during the past year. The present volume is prefaced by a sketch of the life of Mr. Joseph Whitworth, a faithful portrait of whom faces the title page of the book. The "Year Book" is compiled from the usual reliable sources—the scientific journals-the Mechanics' Magazine amongst the number. It contains a great variety of information on the mechanical and useful arts, natural philosophy, electricity, chemistry, geology, astronomy, &c., and from it the progress made during the past year, in any of these branches of science, may be correctly ascertained. Those who desire to correctly ascertained. Those who desire to inform themselves of this progress, without going through the tedious processes of investi-

gation and research, cannot do better than consult Mr. Timbs' pages.

We have recently had to notice several trade circulars, which are got up in such a way as to form useful books of reference in many cases. Unquestionably, the best which has yet appeared has just been issued by the engineering firm of Appleby Brothers, Emerson-street, Southwark, and is published by Messrs. Spon, of Charing Cross. It contains some 450 pages, and forms a capital illustrated handbook of machinery and ironwork. In it are to be found the cost, working expenses, and results obtained in the use of steam and hand cranes, pumps, fixed and portable steam engines, and various other machines, with weights and measurements, &c. There are also the prices of tools, ironwork, stores, and materials required by civil and mechanical engineers and merchants. There are, besides, numerous tables and useful memoranda, the whole forming a ready book of reference on the subject of machinery The illustrations are prepared in in general. the best manner, and the type and binding are in Messrs. Spon's usual excellent style As a sample of the work, we give, on another page, a description of Furness and Slater's

steam filth hoist, by Appleby Brothers. Another elegantly bound and useful volume similar in character to the last, has just been issued by Messrs. Gwynne and Co., the hydraulic and mechanical engineers, of Essexstreet, Strand. It contains some useful remarks on drainage and irrigation, to which purposes Messrs. Gwynne's centrifugal pumping machinery is so well adapted. The engravings are well got up, and illustrate the various manufactures of the firm, and their

"Treatise on Valve Gear with Special Consideration "Treatise on Valve Gear with Special Consideration of the Link-Motions of Locomotive Engines." By Dr. Gustav Zeiner. Third Edition. Translated by Moritz McLler. London: E. and F. N. Spon, 48, Charing-cross. 1869. † "The Year Book of Facts in Science and Art." By JOHN TIMES. London: Lockwood and Co., 7, Stationers' Hall-court. 1869.

We need not point out special application. the many advantages of the centrifugal pump, which are well known from their extensive application. It is enough to say that Messrs. Gwynne have made this a special branch of manufacture, and they have brought it to such perfection that their pumps are being used for every conceivable purpose, with thorough success. Besides these pumps, Messrs. Gwynne manufacture every kind of hydraulic machinery, which is set forth in the book under notice.

The ninth volume of the "Transactions of the Institution of Naval Architects reached us a few days after the tenth annual meeting had commenced its sitting. It has put in a rather tardy appearance, which we thought was to have been facilitated rather than otherwise by the arrangements the council of the Institution made with one of the engineering periodicals, to which an exclusive right has been given to the use of the papers read, as against all other members of the press. However, it matters not to us, as we noticed at length the papers the volume contains at the time they were read a year since. But we conceive it must matter a little to the members and associates of the Institution, who were not able to be present at the meeting, that the report of the papers then read are not published until after another annual meeting has been held.

We are glad to see that Mr. Joseph Hogg has found it necessary to issue a fourth edition of his "Iron Trades' Guide," as it is of itself an evidence of the practical value of the book. This treatise comprises a series of tables on the weight and measurement of metals, stone, and timber. It also goes into the strength of materials, and the Govern-ment chain and anchor tests. Then we gather much valuable information respecting the tests of iron and steel of different makers, besides which, we obtain an insight into boiler making, forging, smith's work in general, iron rolling, moulding, pattern making, &c., &c. Proceeding to higher branches of the subject, Mr. Hogg gives some articles on girder making, sectional areas of angle irons, and pile driving. Then he adds a series of tables suitable for all kinds of business purposes, and a set of tables of weights, measures, and prices of oils. We thus have nearly 600 pages of matter of the first value to those engaged in the iron

Mr. Henry Dircks, C.E., &c., has just published, through Messrs. Spon, of Charingcross, two lectures on "Scientific Studies, or Practical in Contrast with Chimerical Pur-These lectures were delivered at the Literary Institution, Greenwich, so far back as February, 1864. The first is on the life of the Marquis of Worcester, the inventor of the steam engine, and with whom Mr. Direks has made us familiar in many pleasant ways. The second lecture is upon the chimeras of science, and includes astrology, alchemy, squaring the circle perpetual motion, &c. The lectures circle, perpetual motion, &c. The lectures are written in a popular style, and are well worthy of persual by the curious.

The thirty-sixth annual report of the Royal Cornwall Polytechnic Society (Simpkin and Marshall) is to hand. It contains a notice of the proceedings of the society for the past year, and an account of the various lectures. Amongst other communications on various subjects, is one upon the working of the Dering rock-boring machine. From this report, we gather that Doering's engine had been worked in the 185-fathom level in Tincroft Mine, conjointly with another, from the 6th of January up to September, 1868, and had driven sixteen fathoms in hard tin capel, which Captain Teague considered would cost £20 per fathom if driven by hand labour. During the greater part of that time (in consequence of the air pump getting constantly out of repair), the machine was only worked by one corps of two men; and continuous working with three corps, comprising five men

<sup>\* &</sup>quot;A Practical Treatise on the Manufacture of Worsteds and Corded Yarns." Translated from the French of CHARLES LEROUX by HORATIO PAINE, M.D., and A. A. FESQUET, Chemist and Engineer. Philadelphia: Henry Carey Baird, 406, Walnut-street. London: Trubner and Co., 69, Paternoster-row. 1869.

and one boy only, commenced on the 6th of Since that date nearly nine fathoms of ground had been driven at a cost of £17 18s. 2d. The following is the cost of working the boring machine during October, 1868:—Five miners and one boy, £24; one boy to remove rubbish, £2; two enginemen at surface, £6; one smith and boy, £5 5s.; oil waste and candles, £3 9s.; gun cotton for blasting, £4 10s.; fuse, 7s. 6d.; sundries, 3s.; coals, £6; repairs, £2; total, £53 14s. 6d. In this estimate, the sum of £21 5s. is for expenses at the surface, which would be slightly increased if three ends were driven instead of one, say about £2 15s.; this would reduce the average cost per fathom to £13 9s. 10d., instead of £17 18s. 2d. During the last three months, one corps has been worked by one man and a boy, and the result has shown that they will drive as much ground with the machine as two men could do in the same time.

"The Journal of the Royal Agricultural Society of England" (Murray, Albemarlestreet), contains the usual amount of valuable information relating to the various departments of husbandry. The most useful paper in the volume to agriculturists is that by Mr. J. C. Morton, in which he teaches "Some of the Agricultural Lessons of 1868." The produce of the past year was, in this country, grown under such extraordinary conditions, that Mr. Morton's agricultural history of the year cannot fail to prove highly instructive.

Mr. Henry Coxwell, the renowned aëronaut, has edited the "Aerostatic Magazine for It is a record of ballooning and flying during the past year. Mr. Coxwell deals very severely with the weak points of the Aeronautical Society, especially its exhibition at the Crystal Palace last summer. Coxwell despairs—and very reasonably, tooof flight ever being achieved by man by means of the appurtenances natural to birds. He disbelieves the guidance of balloons to any useful extent, but feels assured that a fair examination of the true principles of flight will advance aerial navigation.

Mr. Sampson Sandys published a problem for trisecting an angle geometrically in 1864. Having recently detected an error in it, he has corrected it, and now submits it to the judgment of geometers. The author has added to it a problem for doubling the cube geometrically. Mr. Westerton, of Hyde Park Corner, is the publisher.

OTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

A NEW METAL-BLEACHING WOOD STUFF-AN IM-

PROVED BATTERY—TUNGSTEN STEEL.

THE discovery of another metallic element, by means of spectrum analysis, is again announced—this time by Mr. Sorby, who found it in the course of an examination of some Cevlon hyacinths or jargon (zircon), as the stone is sometimes called. Hence, Mr. Sorby proposes to call the new metal jargonium. The characteristic spectrum of the supposed new element is a series black absorption bands, and in connection with these, it is right to mention that Professor Church, who is well known by his researches on some of the rarer and more expensive minerals, had noticed in 1866 that some zircons gave a series of black bands, from which he then inferred the presence of a new element, and pro-posed the name nigrium for it. Earlier still, Svanberg, by a chemical examination of zircon, came to the conclusion that it contained a till then undiscovered element, which he did not succeed in completely isolating from zirconium, but for which he suggested the name norium. Whether the metals thus independently discovered are one and the same, or three distinct elements, remains to be settled by a more com-plete examination. We fancy, however, that there can be little doubt that Professor Church's nigrium and Mr. Sorby's jargonium are identical. The minerals which contain these metals are so rare that the discovery is of little importance, except in a scientific point of view. But we must quote one practical application of Professor Church's discovery, which he pointed out in the "Intellectual Observer" for May, 1866.

The orange hyacinth, which shows these black lines very distinctly, is extremely rare, and very precious, and another and cheaper stone, cinnamongarnet, is commonly sold for it. This latter gives no black bands, and hence the spectroscope affords a ready means of detecting the imposition.

Wood stuff, for paper making, is difficult to bleach. Chloride of lime gives it a yellowish colour, instead of turning it white, and, if the stronger acids be used, the stuff is apt to turn red, when exposed to air, sunlight, and moisture: more especially, if the acids employed contain a little iron. Orioli states that oxalic acid is the best bleaching agent to employ. He uses it in the proportion of four-fifths of a pound of the acid to 1001b. of the stuff, and adds as well 21b. of sulphate of alumina, which must be free from iron. The oxalic acid bleaches, and the alumina, it is said, fixes the decolourized matter as a colourless lake. Oxalic acid is a very good bleaching agent for many animal and vegetable substances.

We have recorded so many improvements (as they are all called) in galvanic batteries, that the number and variety becomes bewildering. The last we meet with is that suggested by Böttger, who proposes to substitute metallic antimony for An amalgamated zinc plate is immersed in a strong solution of common salt and sulphate of magnesia. The antimony, like the carbon, is placed in a porous pot; but the liquid used is dilute sulphuric acid. A combination of this arrangement is said to give a stronger and more lasting current than a cell of Daniell's battery

It is many years since Mr. Mushet proposed to alloy iron with tungsten in the formation of steel. We reported a year or two ago that M. Leguen, in France, had made experiments with the same alloy, employing iron converted by Bessemer's process. Then he used a common grey pignot fit for conversion, but produced, novertheless, an alloy of very good quality. Lately he has continued his experiments, now employing good white cast iron, and has produced a steel of excellent quality. A portion A portion of the iron is first alloyed with one-tenth wolfram. in a cupola furnace, and is added to the rest in the convertor. The conversion is carried further than usual, so that the carbon is reduced to onehalf the ordinary proportion. The steel so produced is soft, but very tough, and tempers remark. ably well. M. Leguen mentions that it will be found extremely useful for machines, some parts of which require to be tempered while others are kept soft. The objection brought against this alloy is that it is expensive, but the amount of tungsten employed by M. Leguen is so small-only 0.55 per cent.—that it can make but a very small addition to the cost of the steel.

# ON THE USE OF LOGOTYPES. By C. W. Felt.

A T a meeting of the Manchester Literary and Philosophical Society, held March 9, 1869, the following paper on the Use of Logotypes, by Mr. Charles Wilson Felt, of Salem, Massachusetts, was communicated by Professor Jevons, M.A.:-

I have recently brought to England, for the purpose of practical introduction, a series of inventions for the more rapid composition of printer's typo. These inventions have been gradually perfected during many years spent in experimenting; but as my present purpose is to notice only one of the auxiliary improvements, I pass over the mechanical inventions with the remark that the difficult operation known as "justification," and supposed by printers to be beyond the possibilities of mechanism, has been

successfully accomplished.

The work of the printer is of course largely controlled by the nature of language, and yet typographers seem to have entered the domain of literature only so far as to make a somewhat rude estimate of the number of the various letters and characters employed. It has been many times suggested that two or more letters might be cast together, or even whole words cast in and many times, too, have these suggestions proved unsuccessful in practice. One of the earliest attempts was made by Earl Stanhope, who laboured most earnestly to improve the low condition of the printer's art in his time, and though the Stanhope press succeeded, the logotypes were a failure. more successful scheme was conceived some twenty years ago by Mr. John H. Tobitt, son of a London choolmaster, who emigrated to America when a boy, and afterwards established himself as the "Combination Type Printer." His success was His success was acknowledged by the grant of silver medals at the

No previous systems, however, were based upon careful attempt to discover a law of language, so that but very few logotypes have been adopted in common by different experimenters, and each has launched off into a series of his own, strangely varying from those of others. A little reflection must convince us that few things are more amen-able to the rule of averages than the frequency of combinations of letters, provided that we be willing to undertake the labour requisite to ascertain the most frequent combinations in a thorough

It is a curious instance of the rarity of original investigation that we have been willing to spend great amounts of time and money without making the proper inquiry into the comparative frequency of words and combinations of letters. Mr. Babbage, while engaged upon his calculating engine, had occasion to examine tables of logarithms, and discovered that the same errors were to be found in various tables which were supposed to be founded on original calculations. Certain Chinese tables were even found to be copies of the same defective originals, and it is wonderful how ready men are to copy the imperfect labours of others, rather than to undertake the task thoroughly themselves.

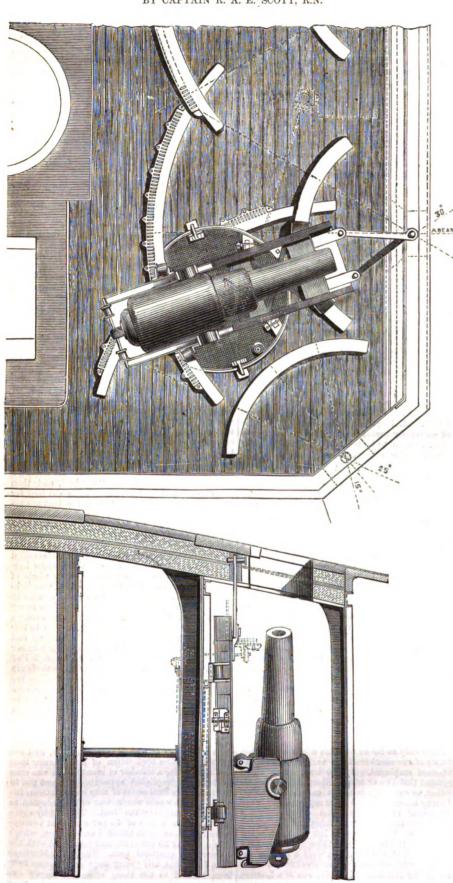

Ten years ago I took this matter in hand, and gradually reduced it to a system which is applicable to other languages as well as the English. My aim was to discover a number of the most frequently occurring combinations, large enough to make a considerable gain in composition, and yet not so large as to render the printer's case inconvenient or to overtax his memory. After some preliminary trials, twenty-five samples of English composition were ultimately selected from the following classes of literature:—Current literature, newspapers, standard authors, scientific works, legal works, modern poetry, old English prose, old English and burlesque poetry. Three of each class, except the last, were fairly selected, and 10,000 characters (or 250,000 in all) were taken from each for the sake of easy comparison. The samples were then subjected to an exhaustive analysis, a table being made of twenty-six lines and twenty-six columns one for each letter of the alphabet, and in each space were placed the number of times the letter at the left of the line immediately preceded the letter at the top of the column. Thus the word "column" would give the combinations co, ol, lu,
um, and mn. The first and last letters of a word, indeed, can appear but once, while the others appear twice, but the table gives a correct idea how many times two letters are found in conjunction in a sample of 10,000 characters.

The next step was to select the best, and then recur to the text, and carefully trace out how far those combinations which appear the best are injured by other combinations. For instance, in the word "are," shall we take ar or ie? Both are word "are," valuable, and it is a question for another investigation whether the whole word should not be taken. To complete this investigation certain tables called "glossaries" have been formed, which show how many times each word is repeated in the whole of samples and in each 1,000 characters. These glessaries have been printed in an octavo volume of 514 pages, and it is surprising to find how many words occur but once in samples which average about 2,000 words, and contain from 500 to 900 different words. Another table is made up and also printed, showing the words and their number occur more than once in the nine samples of matter in most frequent use, and of these there are These tables, besides re-1,103 different words. vealing many interesting facts, prove conclusively that any attempt to cast the whole words must be limited, and that the greatest care should be taken to select the best.

The work of comparing the various combinations to ascertain how far they would interfere with each other, was of a most tedious nature, and re-quired the close application of many young men and women for a number of months. It was once or twice accomplished approximately and put to the test, and a final series of fifty combinations, including some whole words, was at last adopted as being demonstrably the best. These fifty combinations give a gain of 35 per cent., but twentythree have been again selected out of them, which give a gain of 25 per cent., and have met with the approval of practical men. These combinations have been cast, and young men and women have been trained to use them upon newspaper and other work. Practice has thus been founded upon theory, and it need only be further pointed out that, the combinations once determined, are applicable not only to printing, but to telegraphy and phonography.

### GUN-WORKING MACHINERY ON BOARD "HERCULES." H.M.S.

BY CAPTAIN R. A. E. SCOTT, R.N.

GUN WORKING MACHINERY OF THE "HERCULES."

IN our issue for January 22 last, we described and illustrated Captain Scott's turntable system of working broadside guns. We now give particulars of that system, as carried out in the "Hercules," by the inventor. It has been adopted by Mr. E. J. Reed, the Naval Chief Constructor, in the casemate of that fine vessel. It will be seen that by means of the gear work shown by the dotted lines the turntable is caused to by the dotted lines the turntable is caused to revolve much in the way frequently adopted at railway stations. By means of the rack racers the gun can be trained right and left when in the port without further aid from tackle. The corner port looks forward and enables the gun to be fired in a

looks forward and enables the gun to be fired in a line within a few degrees of the keel.

In a recent trial of these gun carriages on board the "Hercules" they appear to have given the utmost satisfaction. On the arrival of the vessel at Lisbon, Admiral Sir T. Symonds, commanding the Channel Squadron, took his squadron to sea for an eight days' cruise immediately. The weather was stormy, blowing a N.E. gale, accompanied by violent squalls of hail a great part of the time. The confidence and ease with which the men handled the ponderous 18-ton guns, mounted upon the new pattern Scott carriage, and the wide sweep attainable by each broadside gun, astonished the inspecting officers, while the vessel was working round and firing at a target. The steadiness of the "Hercules" as she presented her broadside to the Atlantic swell and the wonderfully quick manner in which she obeyed each motion of her helm while moving round the target, elicited unhelm while moving round the target, elicited unqualified admiration.

#### MINING PRIMERS.

SINCE the appearance in our columns of a paper CINCE the appearance in our columns of a paper on "Explosive Compounds for Engineering Purposes,"\* read before the Society of Engineers by Mr. Perry F. Nursey, we have had several enquiries respecting the new method of exploding charges adopted by Mr. Nobel for dynamite, and the Patent Safety Gun Cotton Company for their compressed gun cotton. This method, it will be remembered, consists in using a detonating fuse, which is inserted in the charge, and which developes all the active energy of an otherwise company. velopes all the active energy of an otherwise comparatively harmless material, in the open air. These mining primers, as they are termed, are prepared for use with the ordinary time fuse, as well as for electrical firing. The accompanying cut shows

one of these primers, which consists of a copper tube A, containing the fulminate, B is the ordinary mining fuse, which is inserted in the tube. In firing a shot, the fuse is inserted in the tube, the iring a shot, the fuse is inserted in the tube, the opening C being nipped upon it with a pair of pliers. This tube is then inserted in the fuse-hole of the charge, within about \(^3\)\_in. of the point C, and afterwards fired. Under all circumstances, a greatly increased effect is stated to be produced by the use of these primers in firing gun cotton charges, but more especially will their value be manifest in broken ground or rock, where otherwise the full power of gun cotton is not developed.

developed.

The value of the invention and its wide application will be understood when it is explained that an ordinary charge of compressed gun cotton placed on the ground and ignited by an ordinary fuse or match burns without explosion and comparative charge contributions. fuse or match burns without explosion and comparatively slowly, producing no destructive effect; whereas a similar charge, still unconfined, fired by a fuse with the primer attached, explodes with a report like a cannon, producing destructive results greater than those obtained with gun cotton fired in the ordinary way, under conditions most favourable to its action. In quarrying and mining, it is found that with the use of these primers there is no absolute necessity for tamping, but the hole no absolute necessity for tamping, but the hole may be fired at once upon the insertion of the charge. It is best, however, to pour down some loose sand or broken rubbish to hold the fuse in position. For submarine work, it has hitherto been necessary to confine the charge in very strong cases or shells in order to develope its power. With the use of these primers, however, the full effect is obtained without any such assistance, it being only necessary to enclose the charge in a water-tight case or cover. water-tight case or cover.

• MECHANICS' MAGAZINE, February 5, 12 and 19, 1869.

LEDGER'S RAILWAY SIGNAL.

MR. HENRY LEDGER, builder, of Hulme, is now exhibiting in Manchester a working model of an apparatus for railway train signalling, which, from its entire novelty, and inexpensive character, will doubtless receive the attention its merits deserve from the managers of railway companies. Mr. Ledger provides a thoroughfare of ample dimensions through the whole length of the carriages, and from one carriage to another, if necessary, by forming a doorway and fitting a door to each compartment, and, if necessary, at the ends of the carriages. These thoroughfares and doors are above the seats, and the doors slide up and down in grooves behind the seats, so that when closed they afford all the privacy to each compartment which at present exists. When closed, the doors are fastened by means of a self-acting hook, which is acted upon by a lever connected to a rod, running along the whole length of the roof of the running along the whole length of the roof of the carriage. In each compartment a chain is suspended, which is connected to an arm branching from the longitudinal rod, so that when the chain is pulled by a passenger, the longitudinal rod turns partially, and thus the hooks release all the doors in the carriage, and open up a communication through the sliding doorways between all the compartments. At the same time, the doors, in falling, come in contact with two levers connected by chains, passing over guide pulleys to semaphore signals mounted on each side of the carriages, so signals mounted on each side of the carriages, so that the semaphores are thrown out to signal in which carriage the guard is wanted. At the same instant, the chains connected with the actuating lever of the semaphores, by means of a peculiar clutch attached to them, pull the ordinary cord or rope which passes from one end of the train to the other thus actuating the harmons of according to other, thus actuating the hammer of a gong either in the guard's van, or on the engine, or both; or, if connected with the steam whistle, it sounds an alarm. An indication is also given from which compartment the chain has been pulled, by a selfacting latch, which, when once released, renders it impossible to replace it in its original position without the use of a key made expressly to suit it. The whole mechanism of this apparatus is enclosed, so that it is impossible to tamper with it.

NOVEL AND USEFUL APPLICATION OF THE ABYSSINIAN PUMP.

MR. H. HALL, of Sheriff Hill Colliery, has succeeded in applying the principle of this invention, with complete success, in a mining operation of no slight difficulty. The circumstances under which the application took place are thus detailed in the "Newcastle Daily Chronicle":—A particular seam of coal was subject to inundation from a large feeder of water, rendering a great amount of pumping power necessary in the working of the coal. The water was found to proceed from an old pit, which had been smk many years ago to the deeper and more valuable seams, and had become gradually filled with rubbish, consisting principally of old shaft timber, stones, &c., up to the level of the seam in question, thus forming an obstruction to the water, which otherwise would have passed down the shaft and found an outlet at a lower level by means of old workings. Numerous attempts had previously been made by boring to pass the water down, but without success, the timber seeming to form an impassable barrier. Mr. Hall being favourably impressed with the success which had attended Mr. Norton's patent for sinking wells, resolved to test its capabilities in passing through a material which had been proved impenetrable to the common bore rod. Mr. Ridley, from Messrs. Mather and Armstrong, of Newcastle, licencees of the patent, undertook the management of the apparatus. An 801b. weight and a 14-inch tube were used. When two hours had expired from the commencement of the operation, the tube was found to have been driven a distance of 20ft., the speed varying considerably. The succeeding 15ft. were overcome in four hours. At this point the process became much slower, but never stationary, the next 3ft. requiring two hours' labour; then 3ft. at a considerably increased speed, occupying only half an hour. The water was now laid on to the pipe and found to pass freely, and the driving was discontinued, 41ft. having been overcome in eight hours and a-half. Had it been necessary, it seemed quite possible to have driven the tubes to the ext

FLOATING OF THE "CAPTAIN."

AST Saturday witnessed the successful floating of the "Captain" from the works of Messrs. Laird Brothers, of Birkenhead. This vessel was designed by Captain Cowper P. Coles, R.N., C.B., designed by Captain Cowper P. Coles, R.N., C.B., and is the embodiment of the turret system with which the gallant officer's name has become identified. The principal dimensions of the "Captain" are as follow:—Length over all, 335ft; ditto between perpendiculars, 320ft.; breadth extreme, 53ft. 3in.; tonnage, 4,272 tons; draft of water abaft, 23ft. 6in.; ditto forward, 22ft. 6in.; height of freeboard or upper deck gunwale above water-line, 8ft.; beight of portsill in turrets above water-line, 8ft.; height of portsill in turrets above water-line, 10ft. There are two separate pairs of double trunk engines, each pair driving a separate serew propeller 17ft, in diameter. The collective nominal power is 900-horse power, and the in-dicated horse power will be not less than 5,400. There are surface condensers, jacketed cylinders, and appliances for economizing fuel. The four cylinders have each an effective diameter of 80 in., with a stroke of 3ft. 3in. The steam is supplied from eight boilers, having twenty-eight furnaces. The hull of the ship is wholly protected by armour fitt below the water line to the water line. The hull of the ship is wholly protected by armour from 5ft. below the water-line to the upper deck gunwale, right fore and aft, thus affording complete protection, not only to the midship part of the ship, where the machinery and turrets are placed, but also to the quarters for officers and men. The thickness of armour opposite the turrets is 8in., and on the remainder of the midship portion 7in., slightly reduced towards the ends. These plates rest on a backing of East India teak 12in, thick, through which they are bolted to the skin of the ship, which is 14in. thick (formed of two 4in. plates), the whole supported by massive framework 10in. deep. This backing is further supported by longitudinal girders 10in. deep. The upper deck at the level of the top of the armour is covered with iron 1½in. of the top of the armour is covered with iron 1½in. thick for the length of the turret spaces, and with lin, over the remainder, supported by iron beams 14in. deep and covered with teak 6in. thick. The general construction of the hull of the ship is similar to that of other large armour-clad ships built for her Majesty's navy, and combines a complete arrangement of water-tight compines a complete arrangement of water-tight double bottom, wing passage and other bulkheads. The fore-end especially is made of enormous strength, and terminates in a massive wroughtiron stem, formed as a ram for running into an enemy's ship.

The arrangement of the "Contraction"

enemy's ship.

The armament of the "Captain" will consist of six guns, four of which are to be carried in the turrets, and two on the upper deck. The guns in the turrets are to be 600-pounder 25-ton guns; those on the upper deck, at the fore and aft end, are to be 100-pounder 64-ton chase guns. The turrets, two in number, each carrying two 600-pounder 25-ton guns, project through circular openings in the upper deck. That part exposed to shot is covered with armour-plates 10in thick about the ports and for one-third the circumference, and with plates 9in thick for the remainder; while the lower part of all the gearing is protected by the 8-inch armour on the sides of the hull. The height of the centre of metal of the guns is 12ft. above the water-line, which will admit of them being fought at sea in very heavy weather; and they will have an are of training from the foremost turret of 154deg., and from the after turret of 156deg. The turrets are each 27ft. external below the armour shelf is constructed in a cellular form, large openings being left for entrance and for and 22tt. 6in. Internal diameter. The lower particle below the armour shelf is constructed in a cellular form, large openings being left for entrance and for passing in ammunition. These openings serve also to ventilate and light the lower decks. The turrets are supported by a strong girder on lower deck, and revolve on a series of cast-iron rollers, being kept in position by a solid wrought-iron central spindle, securely fixed in the deck and carried down to the orlop deck, and are fitted with a complete system of hand-turning gear in addition to the steam gear. This steam gear is worked by a separate pair of engines for each turret, placed on the orlop deck below the turret, where they are thoroughly protected from any chance of injury. The gear for starting these engines is so arranged that it may be worked either on the lower deck outside the turret, or, by a system of rods, led up through the central spindle to the sighting platform by the captain himself, who can thus take aim and direct the guns in the turret.

the turret.

The "Captain" is built with a poop and forecastle, which offer advantages when steaming head to wind at sea, and, in the present case, offer but little obstruction to the training of the guns. The poop and forecastle are connected by a centre spar deck, 26ft wide, which runs over the turrets, giving free communication from one end of the ship to the other, in all weathers; and the area of this deck will be sufficient to admit of the whole working and maneuvring of the ship. The hatchways round the funnel and amidships are carried up of iron, forming at once a the turret.

support to this deck, and a system of ventilation permanently trunked up to a height of some 23ft, above the load water-line. In order to enable this deck to resist the concussion from the explosion of deck to resist the concussion from the explosion of the guns when fired beneath it, it has been framed of iron, the part over the turrets where it is necessarily unsupported being carried by deep fore and aft girders, which will be used as hammock nettings, and the whole of the under side\_of the beams being plated over with steel plates. Arrangements are made on spar deck, forecastle, and poop for storage of boats, anchors, &c., and there is a complete fixed bulwark 3ft. 6in. and 4ft. high all round. The space thus provided for working the ship leaves the upper deck clear from the poop to the forecastle for the training of the turret guns, one of which can be fired from within 6deg. of the line of the keel forward to 6deg. of the line of keel aft, the only obstacle being the foot of the main tripod, which occupies but little space. Light iron stanchions, fitted with wire rope, take the place of hinged iron bulwarks at the upper deck level, and are lowered into the hollow water way when preparing for action.

The "Captain" is fully rigged as a ship. The

water way when preparing for action.

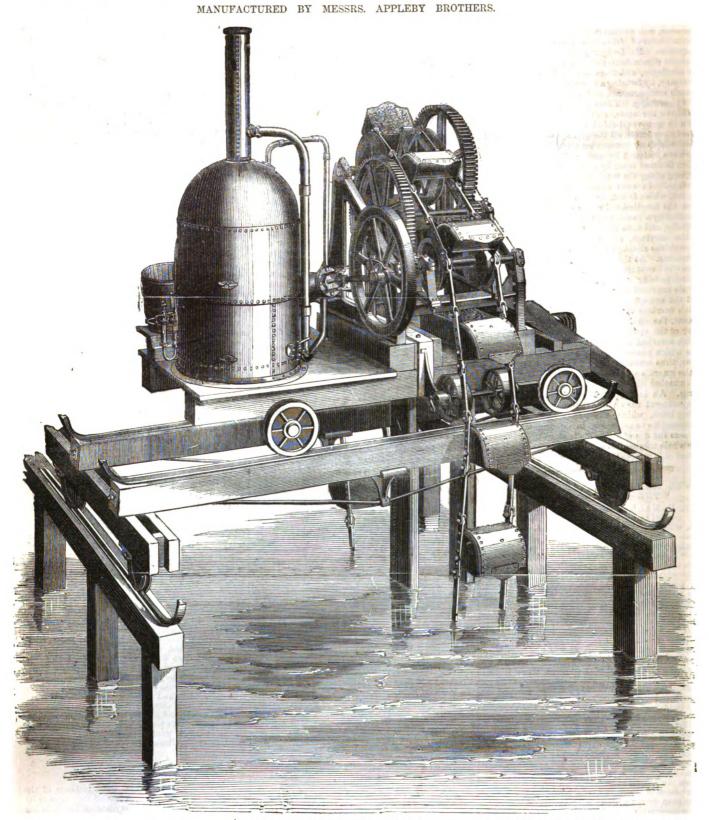

The "Captain" is fully rigged as a ship. The lower masts, which are made of iron, are on Captain Coles' tripod system, and are so arranged, that the tripods of the foremast and mizenmast come into the forecastle and poop, and the upper rigging is attached to the spar deck, above range of fire. There is, therefore, no obstruction to the training of the guns, except from the foot of the main tripod, one great objection to the turret system for sea-going full-rigged ships, namely, having the fire of the guns masked for the whole length of the rigging, or, on the other hand, risking the safety of the masts by letting go all but one or two shrouds, is, therefore, avoided. The space under the poop and forecastle, and between the upper and lower decks, is appropriated to the accommodation for officers and crew. The two turret spaces are particularly roomy. In the centre part a large space is bulk-headed off so as to be used as a supplementary coal bunker, holding about 200 tons of coal, in addition to the 600 tons which are to be stored in the regular bunkers. Below the lower deck are the magazines, shell-rooms, water tanks, prevision rooms, and all the storerooms, in the lower deck are the magazines, shell-rooms, water tanks, provision rooms, and all the storerooms, in addition to the engines, boilers, and coal bunkers. addition to the engines, boilers, and coal bunkers. The magazines and shellrooms are very conveniently arranged, there being two of each, one below each turret, so that the shot and shell may be hoisted direct into the turret spaces. Captain H. T. Burgoyne, R.N., V.C., has been appointed to the command of the "Captain," which now lies in the Alfred Dock, completing her internal fittings.

the "Captain," which now lies in the Alfred Dock, completing her internal fittings.

It will not be uninteresting, inconcluding our notice of the "Captain," to refer to those vessels which have been previously constructed by Messrs. Laird, upon the turret principle as developed by Captain Coles. These have been the "Scorpion" and the "Wivern," of 1.800 tons, and 350-horse power, each vessel carrying two turrets armed with two 300-pounder guns in each. The "Huascar," built for the Peruvian navy, of 1,100 tons and 300-horse power, with one turret carrying two 300-pounder guns. The "Bahia," for the Brazilian navy, of 900 tons and 140-horse power, with one turret carrying two 150-pounder guns. The "Lima Barros," for the Brazilian navy, of 1,323 tons and 300-horse power, carrying two turrets with two 150-pounder guns in each. The "Prince Hendrik," for the Dutch navy, of 2,100 tons and 400-horse power, carrying two turrets with two 306-pounder guns in each. The "Helligerlee" and the "Krokodil," for the Dutch navy, of 1,525 tons and 140-horse power, each carrying one turret with two 300-pounder guns. The "De Stier," for the Dutch navy, of 1,326 tons and 350-horse power, carrying two turrets with two 300-pounder guns. The "De Stier," for the Dutch navy, of 1,326 tons and 350-horse power, carrying two turrets with two 600-pounder guns in each. Making in all, ten ships, carrying fifteen turrets and twenty-six heavy guns.

Science and Art.—A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brooches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[ADVT.]

# SLATER'S DREDGING MACHINE. MESSRS. FURNESS AND

FURNESS AND SLATER'S STEAM EXCAVATING AND DREDGING MACHINE OR FILTH HOIST.

THE annexed engraving represents this simple and efficient machine at many and efficient machine at work upon a staging, excavating under water previous to sinking iron caissons, or making a coffer dam of the ordinary construction for sea or river walls, docks, founda-tions of piers, &c. The characteristic features of this machine consist in its great simplicity, effi-ciency, and economy, and that it will excavate under water, sand, gravel, or clay, at infinitely less cost and time than by bag and spoon, divers, or any other mode of working hitherto adopted; that the work may be carried on continuously in any state of the tide, and that when the coffer dam has been formed, the entire excavation of the dam

may be accomplished by this machine without the great expense and loss of time usually incurred in pumping, tide work, &c. Some idea of the working expenses may be formed from the fact that it usually excavates from 20 to 30 yards of stuff, lifting it from a depth of 40ft., and discharging it into a barge within the hour, the hands employed being—one engine driver and two labourers, and the consumption of fuel 40lb. of coal. For sea or river works, the machine may be worked as an ordinary dredger fixed on a barge, or as an exca-

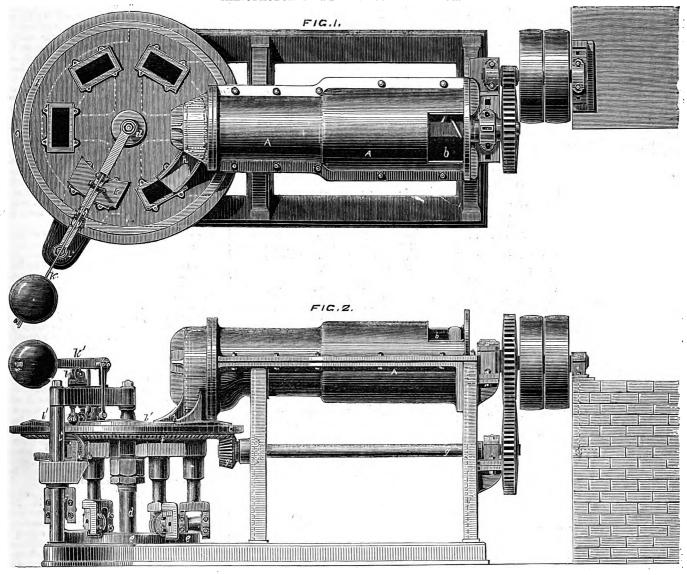

venient position. For working upon a staging, the whole is mounted on a truck which travels, and can be readily moved, either longitudinally or transversely, on a gantry similar to those used for an ordinary overhead travelling crane, and which can usually be made of sufficient span to take the whole of the excavation. The jib or ladder for carrying the buckets is in the form of a telescope slide, and may be elongated as the work progresses, to any required length up to 40ft. or 50ft. It is hung underneath the machine on a centre pin; vator travelling on staging, as may be most convenient, and after being used on the one, it may be readily transferred to the other. It is equally applicable for excavating cuttings for railways, sewers, or any similar work.

The engine is attached to the main framing of the machine, and the boiler is placed in any contracted places, or take a long face of work, as required. In excavating clay or other intractable strata, there has hitherto been considerable difficulty in discharging the buckets, but in this machine there is a self-

#### JOHNSON'S BRICK-MAKING MACHINE.

MANUFACTURED BY MR. T. R. TAYLOR.

acting arrangement, which entirely empties each bucket as it arrives over the shoot which conveys

it into the barge or waggon beneath.

As the main drainage in towns is at present greatly on the increase, the inventors have especially greatly on the increase, the inventors have especially adapted this machine (with some slight modification), as a filth hoist, at pumping stations, for elevating the sewerage from low level to high level, there being always a considerable deposit that pumps will not bring up. The patent has been purchased by Messrs. Appleby Brothers, of Emerson-street, Southwark, who are the sole manufacturers of the machines, and from whose recently published "Handbook of Machinery and Ironwork" we have extracted the above partiwe have extracted the above particulars.

# BRICK-MAKING MACHINERY.

MR. C. G. JOHNSON, of Portrack House, Stock-M. C. G. JOHNSON, of Portrack House, Stockton-on-Tees, has recently patented some improvements in machinery for making bricks. These improved machines are now being manufactured by Mr. Thomas R. Taylor, of the Cargo Fleet Steam Brick Works, Middlesbrough, who has also introduced in them the very efficient oil die and self-acting cutter of Mr. S. S. Anderson, of Bishop Anokland. Mr. Taylor has also combined with it Auckland. Mr. Taylor has also combined with it his excellent pug mill, so that the apparatus as turned out, includes three distinct patents. In the present arrangement, the principle is the employ-ment of Mr. Taylor's pug mill, in combination with moulds set in a table, revolving beneath an aperture in the pug mill. The boxes are brought in succession opposite the orifice of the pug mill, and are filled with clay. The material in the moulds are subjected to pressure by a piston which forms the bottom of the mould, being forced upwards, whilst

the top of the mould is at this time covered over. The bricks are subsequently discharged from the moulds by cams or levers, and are removed. In our engraving, fig. 1 shows a plan view, and fig. 2 a side view of Mr. Johnson's brick-making apparatus. In this machine the pug mill A is placed horizontally, and is fed with clay through an opening b formed through the side of the casing of the ing by formed through the side of the existing of the pug mill at one of its ends. At the opposite end is the exit orifice, and below this orifice is the table c carrying six moulds suitable for moulding bricks. The table is carried by a central pillar d, around which it revolves. The piston or plunger which forms the bottom of each mould has a stacked to it. by a screw or socket. At the lower end of this rod is a roller running on a fixed cam surface e, which is concentric with the axis of the revolving table. On the under side of the table, and near its table. On the under side of the table, and near its periphery, is formed a toothed wheel  $f_i$  into which gears a toothed pinion  $g^1$  on the axis g. This axis is driven by toothed gearing from the axis of the pug mill; thus, as the axis of the pug mill revolves, the table g revolves also, and the moulds carried by it are thus in succession brought below the exit orifice of the pug mill and are from it fed with material to be moulded into a block.

The moulds after passing below the orifice of the pug mill are for a time covered over by a fixed plate h, so that no portion of the top of the mould may be uncovered, whilst any other portion of the top of the mould is below the exit orifice of the mill; the material in the mould is thus left with a more or less even surface. on its top. As the table revolves the moulds are brought under a plate t, which is pressed downwards by the weighted lever t 1. This plate is relieved from pressure at the time when the mould com-

mences to pass under it by the weighted leve being there held up by a roller l at the upper end of the rods, which at their lower end carry rollers running on a cam surface l 1 on the top of the table. The outer circumference of the table is at table. The outer circumference of the table is at this spot supported by a roller, so that no strain may come upon the pivot upon which the table revolves; the axis on the weighted lever  $k^{1}$  is carried by bearings on a bar passing from the top of the central pivot to a pillar l, which stands up at the side of the table from the bed of the material pivot to a pillar l. at the side of the table from the bed of the machine. When the mould is below the plate, and just before the piston which forms the bottom of mould is caused to rise by the cam surface e, the cam surface l<sup>1</sup> on the top of the table allows the lever k<sup>1</sup> to again press down the plate k, so that the top of the mould may be then covered over by the weighted plate, and the amount of pressure to which the materials in the mould may be subjected will be limited by the weight on the lever k<sup>1</sup>. When the moulds have by the revolution of the table been carried past the plate k, the pistons which form the bottoms of the moulds are again caused to rise by means of the cam surface e, and so the moulded bleck is lifted up out of the mould, and is then removed by hand. The moulds are then by the continued revolution of the table again brought under the exit orifice of the pug mill, and are thus again filled with material, which is again subjected to pressure and then discharged as described.

# MAKING AND APPLYING ANILINE BLACK.

A NEW method of producing aniline black and applying it in practice has been patented by Mr. James Higgin, a manufacturing chemist, of Manchester. His improvements in producing

aniline black upon textile fabrics consist, first, in a new method of making chloride of aniline, which salt has been found the best for the production of aniline black, being either used as such in the preparation of the colour or formed during the process of agoing the printed goods by double decomposi-tion. Instead of combining the aniline with an acid as at present when making aniline black printing colour, it is mixed with a solution of a metallic chloride, the base of which is not injurious to the proper oxidation of the aniline. means the aniline combines with the chlorine in definite proportions, and chloride of aniline free from excess of acid is formed. According to the metallic chloride used the metallic base is in some cases either wholly or partially precipitated, and in other cases no precipitation takes place, a liquid being obtained containing aniline, chlorine, and the metal. Mr. Higgin has found the sesquichlorides of iron and chromium most suitable this purpose. When operating with sesquichloride of iron and aniline the proportions used are 100 parts by measure of aniline of commerce, and according to the saturating power of the aniline, from 250 parts to 280 parts by measure of a solution in water of sesquichloride of iron, containing iron equal to twelve grains of peroxide of iron in 100 grains measure.

When operating with sesquichloride of chromium the following proportions are used:-100 parts by measure of aniline of commerce, and from 400 to 450 parts by measure of a solution of seaquichloride of chromium in water, marking 50deg. on Twaddell's hydrometer. These mixtures may be used in place of the chloride of aniline of commerce in the aniline black made with sulphide of copper, using such a quantity as will contain as much aniline as in the quantity of chloride of aniline employed. The inventor prefers to use a compound of copper not hitherto used in making aniline black, and this forms the second portion of his invention. The copper compound employed is the disulphocyanide, which possesses the advan-tage of insolubility in dilute acids, and conse-quently is not dissolved by the chloride of aniline. It has, further, the property of not becoming oxidized in the presence of chlorate of potash until the colour is printed and dried. A soluble copper salt in the colour when printing is thus avoided.

Mr. Higgin makes the disulphocyanide as follows:—He dissolves crystallized sulphate of copper and crystallized sulphate of iron in water in the proportions of two parts of the former and three of the latter, and adds solution of sulphocyanide of potassium or other alkaline sulphocyanide as long as a white precipitate falls. After allowing this to settle he pours off the clear liquid and adds boiling water acidified with muriatic or sulphuric acid, and after well stirring allows it to settle, and pours off the clear liquor. This process is repeated until the precipitate has become perfectly white, when it is poured on a filter and drained until one gallon of the paste weighs 16lb. With this paste, and either of the aniline preparations named above, Mr. Higgin compounds aniline black printing colour as follows :

Number One.—5% pints of water, and 141b. starch; boil and add 8oz. chlorate of potash in starch; boil and add 8oz. chlorate of potash in powder, cool, and when nearly cold add 33oz. measure of perchloride of iron solution (containing in 100 grains measure iron equal to twelve grains of peroxide of iron). When quite cold add gradually 12oz. measure of aniline of commerce, and when this is well mixed add 1 toz. of disulpho cyanide paste; mix well and strain through a cloth. This colour is then ready for printing with. If the aniline is of average saturating power there will be no perchloride of iron in excess.

will be no perchloride of iron in excess.

Number Two.—Five pints of water, 1½lb. of starch; beat up the starch with a little of the water, and add 1½oz. of disulphocyanide paste, add the rest of the water and boil. Add, when cooling, 8oz. chlorate of potash, and when nearly cold, the following solution:—12oz. of aniline of commerce, 54oz. by measure of solution of sesquichloride of chromium at 50deg. of Twaddell's hydrometer; heat at 100deg. Fah. until all the aniline has dissolved, mix well and strain, and it is then ready for printing with. is then ready for printing with.

A good printing black can also be made with the disulphocyanide paste and the ordinary chloride of aniline of commerce, in which case proceed as follows:—One gallon of water, 11lb. of starch; beat up with a little of the water, and add 11oz. of disulphocyanide paste. When this is beaten up add the rest of the water and boil. When cooling add 80s. of chlorate of potash, and when nearly

cold 16oz. of chloride of aniline of commerce in crystals or cake; strain through a cloth, and the colour is ready for printing.

### ON VENTILATION.\* By Dr. EDWARD SMITH, F.R.S. PART 1 .- GENERAL PRINCIPLES.

AM quite aware that there are many persons who seek to increase and on the subject of this paper, whilst there are others who know nothing about it, and who care nothing, so long as they are not interfered with, and others still who regard it as a fashionable folly of the day, but a necessary evil. There are not a few who attach sufficient importance to it to invent a method of ventilation; and I fear that it may be said that there are nearly as many views on the subject as there are advocates of it, so that, in the discussion of this evening, we shall, doubtless, be all of one mind.

It cannot be denied that, of late years, increased attention has been given to the ventilation of public buildings, and that improvements have really effected; but the subject is still novel and in both its theory and practice calls for more accurate and extended information than we possess. We might, therefore, to-night profitably consider any of the several divisions of the subject, such as the abstract principles involved in the movement of the air, the ills which follow deficiency or excess of ventilation, the numerous methods by which architects and others are groping their way with much blundering to a satisfactory result, or specific directions as to the ventilation of each kind of public and private building.

My own experience, official and otherwise, leads me to think that a discussion of a practical nature upon two of these divisions, would be the most useful at the present time, but as they are too extensive for one paper, I purpose to consider only one of them to-night. Those persons who ventilate our public buildings have, I think, a tolerably correct opinion of some of the more obvious principles of the science, but they fail in not duly weighing the limitation of those principles in practice, and thus fall into error. Hence I think it will be useful to attempt to correct these errors, by considering, in a brief manner, some of the principles involved in the science of ventilation, with the methods at present in use, and the conclusions at which I have arrived. The second part, to which I have referred, is the practical consideration of the existing modes of ventilating our private and public buildings, and the plans of construction which are required for different classes of buildings, in order to render them healthy and fitted for their purpose; and this must be deferred to another occasion.

The essential part of ventilation is movement of the air from a particular place. It follows that when a portion of air has been removed from a part of a room, another portion will rush in, and, although it is usually implied that the removed air is less pure than the new supply, this is not a necessary consequence; since ventilation is required even in the open air, and in masses of air of equal purity. No ventilation can be effected without movement of the air, but with the movement other actions follow; and so important are they that movement may be beneficial even when the new supply shall be less pure than the removed air. The regulation of the movement of the air is, therefore, the basis of the practice of ventilation, whilst the character of the new supply is an element which demands careful attention.

The necessity for movement of the air is based upon the requirements of the body and the consti-The body must rid itself of tution of a mass of air. heat and moisture, and of certain noxious and offensive products; the two first chiefly by the skin, the third chiefly by the lungs, and the fourth by various organs. As to heat, the body is warmed various organs. As to heat, the body is warmed chiefly from within by the changes which the food undergoes; and as, notwithstanding any excess in the supply of heat, it is maintained at about an uniform temperature, it follows that it must rid itself of superfluous heat by discharging it into the air. Air is, however, a bad conductor of heat, and when the excess of heat is considerable, the layer of air about the body cannot remove it with sufficient rapidity, but in proportion to the rapidity of the movement (other things being equal) will the heat be more or less rapidly dissipated.
What lady has not proved this by her fan? And in hot weather, or in a hot climate, how delightful it is to hold up the naked hand even, much more to

• Read before the Society of Arts.

expose a large part of the body to the punkah or the breeze. This, it will be observed, is not a question of air at different temperatures, but with air at the same temperature; we may feel hot when the air is stagnant, and cool when it is in rapid motion. Yet, in certain conditions, and in a degree, cooling of the body may be attended with cooling of the air, for it is chiefly effected by the sudden conversion of the fluids of the body into vapour by perspiration and respiration, from which an immense amount of heat becomes latent, viz., loses its sensible effect upon the thermometer, for the latent heat of vapour is about 1,000 times greater than that of fluid. The abstraction of this heat occurs near the surface of the body, and the air in contact with the body and the body itself may become cooler. Hence the body is cooled both by contact with the air, or by transmission of heat, and by evaporation of fluid, or the absorption of heat, and for both processes movement of the air is necessary. The moisture which is emitted from the body is absorbed by the air, but the capacity of the air to absorb moisture is limited, and at a low temperature is soon exhausted. Hence, as one layer of air loses its capacity, there is need for movement to bring a new supply.

But besides these two operations, the sense of comfort and the state of the spirits, and thence of the health, require movement of the air. enter a large room which has been shut up for a long time, and with a sniff of the air you remark its want of freshness. If you stay in it you feel low spirited and unhappy, and yawning, with or without headache, will follow; but introduce a punkah, or adopt any mode by which the air is set in motion, and some sense of relief will follow. So much for the body. But the air itself, in order to keep it somewhat uniform in character and fitted to maintain behaviors.

and fitted to maintain health, must be in motion.

A closed house is generally a damp house. The lower stratum of the atmosphere holds more moisture than the higher. The air surrounding living bodies receives contamination, as it also generally does when in contact with the works of man; and the sewage system and the gas light system of our day do not a little to foul the atmophere. But this applies to a limited portion of the atmosphere, and when the air is in motion other portions not thus tainted are supplied, whilst the contaminating matters become less and less noxious or disagreeable as they mix with the larger volume of purer air, until they are no longer perceptible or efficient for evil. This applies not only to spaces enclosed by four walls, but in some degree to our courts and alleys and even to our streets and towns, for it has been shown by Dr. Angus Smith, Professor Roscoe, and others, that such places, being confined, have the air more contaminated than that in the fields, or on the top of a mountain. Hence we need ventilation to drive the air of rooms into the courts, of the courts into streets, and of the streets into the country, and to draw to us the air the good qualities of which our country friends do not always fully appreciate.

Movement of the air is of two kinds; one always quiet, by the interchange of gases, a physical property which is essential to air and all gaseous fluids by which gases of different kinds mix together, and if enclosed acquire one composition. A whiff of tobacco-smoke, or a jet of vapour of eau de Cologne may be seen or smelt for a moment in a certain spot only, but in a short time, as we know, it extends and impregnates the whole air within certain limits. This is constant, continuous, and without observation, and is of the utmost value in ventilation. It moreover acts in all directions, and is limited only by the amount of the matter to be distributed, and by the enclosure of the whole volume of air. Without this influence the exposure of the body to foul and noxious agents would render life miserable, and in the end would destroy it. How soon would the bedhead, for example, be a reservoir of deadly gases.

The second kind of movement is due to influences acting from without, a body of air. The winds are the great ventilating agents, and their influence penetrates wherever the external air can gain access, but their influence varies with their force and direction, and the obstacles which walls and other impediments offer to the movement of air. Their action must be the basis of any large system of ventilation, and in my opinion they must under nearly all circumstances, be the chief acents.

Similar effects, but more limited in degree, follow mechanical contrivances. The punkah in hot climates, is an illustration, but in this climate the mechanical contrivances. movement of persons in a given space is the most frequent agent, and when we limit our observation to a room, the movement of persons through it and within it, is not by any means without effect. The currents which occur with open doors and windows are due to the movement of the external air in so far as they result from this mechanical action only, for narrowing an aperture in a stagnant room does not produce a current as it would were the air in motion.

The third important cause of motion is that of heat. Air expands 1-480th of its bulk for every degree of heat, Fah., above 328, and, consequently, if we take an ordinary-sized room (say 20ft. long by 12ft. wide, and 10ft. high) there would be an expansion of 5ft. for each additional degree of heat, or a practical loss of 60ft., equal to a layer 3in. deep ever the whole room with or increase of 13te. over the whole room, with an increase of 12deg, of heat. This would be equal to lowering the height of the room from 10ft. to 9\frac{3}{4}ft.—assuming, of course, that no fresh air at the lower temperature were admitted. An essential condition of this change is that the heated air ascends, since it is lighter, and there are currents moving upwards, whilst, at the same time, the air which is colder descends and causes descending and lateral waves or currents until the whole mass has attained an uniform degree of temperature. Every person, and every light in a room, is a cause of these currents, and the room in which we are now assembled is full of them. As the total volume of air increases, it follows that some must escape (unseed to the court of the court o less we assume the room to be air-tight, when, with expansion of the air from heat, there will be condensation from pressure), and this will occur at the top of the room if there be openings, or at the sides, or even at the bottom if there be no other mode of escape. When the air becomes cooler it condenses in volume, and more air is admitted by descending or lateral currents into the room.

With elevation of temperature certain other conditions occur, which have great importance.

The power to cool the body by contact is

lessened.

The air is capable of absorbing a larger amount of moisture, and is relatively drier, until the increased quantity has been supplied.

The skin is rendered more sensitive to cold, and the tendency to perspiration, by which the heat of the body is removed, is increased.

Above a certain degree there is a tendency to exhaustion of nervous power and relaxation of tissues which render an individual less capable of mental and bodily labour; lassitude, low spirits, headache, and indisposition to make any effort, are well-known results of occupying a close and hot room.

(To be continued.)

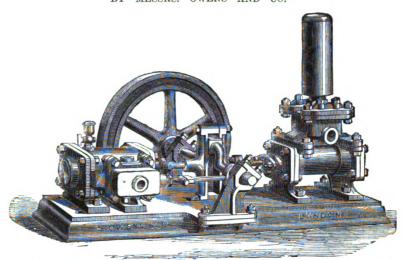

# PROPOSED EXHIBITION AT UTRECHT.

PROPOSED EXHIBITION AT UTRECHT.

An International Exhibition is to be held at Utrecht in August, September, and October next. Its principal object is to improve the condition of the working classes by bringing together articles of household use, furniture, dress, food, and the like, of various countries, at prices combining usefulness with solidity. The place of exhibition in the Netherlands has been changed from Utrecht to Amsterdam, where the exhibition can be conducted on a larger scale, in a building already in existence, specially adapted for exhibitions, and similar in design to the Crystal Palace. The jury for the exhibition will be appointed by the King of the Netherlands, and it will be conducted by a central committee at Amsterdam, of which Baron Mackay is at the head. The Dutch railway between Rotterdam and Amsterdam will carry goods forwards and backwards free of all charges. Within the last few weeks, Mr. P. L. Simmonds, who has had much experience in exhibitions, has, at the request of the London Committee, visited Manchester, Birmingham, Wolverhampton, the Potteries, Bolton, Sheffield, and Nottingham, with a view to ascertain to what extent the manufacturers there would be prepared to join in the exhibition, and, at a recent meeting at the Mansion House, he reported the results of his inquiries. As a rule, such of the manufacturers as are disposed to send goods to the exhibition have an objection to affix the wholesale prices to them, and have few means of knowing the retail prices. The committee thought that a reasonable objection, but were of opinion that it was essential the retail prices should be affixed, so far as those could be ascertained. Eventually, Mr. Simmonds was instructed to put himself in communication with the Central Committee in Amsterdam on matters of detail, and, before the meeting separated, a public subscription was set on foot towards carrying out the English part of the exhibition, the Lord Mayor, as a beginning, contributing £10 10s.; Mr. Samuel Morley, M. P., £25; and t

# STEAM PUMPING ENGINE.

BY MESSRS. OWENS AND CO.

BOATS IN THE NAVY.

ONE of the most important parts of the equipment of a ship of war is undoubtedly her boats and their capabilities. In this respect, the ships of the English navy, a few years since, were far behind those of France or Russia, but at the present time, owing, it must be admitted, to the exertions of the Controller and Chief Constructor of the Navy, they are much more efficiently provided in that respect than the ships of any other nation. For some time after steam-power was applied for the propulsion after steam-power was applied for the propulsion of boats attached to ships of the French and Russian navies, our own authorities stood by oars and sails, and when they did follow on the new track it was only done at first in a compromising and bungling kind of way. In their application of steam-power to boats, our friends aimed at rendering the boat a kind of miniature despatch tender to the ship, possessing as much speed as could be given by the engine and boiler carrying power of her tonnage, without the usual heavy gun at the bow or stern, and with no great capacity for stowage beyond fuel, but with good towing powers, so that she could take a string of heavily armed boats into or out of any position that might be desired on a coast at a moderate speed. Our first efforts in the same direction was to place twin-screw engines and boilers in the heavy built steam launches already attached to our ships, retaining them at the same time in all their original form as gun-carrying boats, with armed crews, and stores of shot, shell, mast, sails, oars, water, and provisions, &c., the clumsy bluffbowed monsters being, when thus loaded, scarcely able to hold their way against a moderate wind or tide in a river way, and useless altogether for towing purposes. The fitting out of two surveying sloops for service in the Chinese and Japanese seas led to the introduction of quite a different class of steamboat into our navy, a type of boat which more nearly approached that adopted in the French and Russian navies in its general principles as simply a despatch and towing boat, but excelling them greatly in having superior speed, combined with the lifeboat principle in the boat's construction, the latter arrangement rendering them unsinkable when filled with water to the gunwale's construction, the latter arrangement rendering them unsinkable when filled with water to the gunwale's construction, the latter arrangement rendering them unsinkable when filled with water to the gunwale's construction, the latter arrangement renderi of boats attached to ships of the French and Russian navies, our own authorities stood by oars and sails, and when they did follow on the new track it was

immersion of the upper edge of 2in. The mean revolutions of the engines were 244-63, and the boat's mean speed was 7.988 knots per hour. No. 13 was tried at a draught of water 3ft. aft and 2ft. 5in. was tried at a draught of water 3ft. aft and 2ft. 5½in., a pitch of 3ft. 4in., a length of 4:in., and an immersion of the upper edge of 3½in. The mean revolutions of the engines were 282-66, and the boat's mean speed 7-288 knots per hour. No. 10 was tried at a draught of water 3ft. aft and 2ft. 8in. forward. Her four-bladed common screw had a diameter of 2ft. 9½in., a pitch of 4ft. 2in., a length of 6½in., and an immersion of the upper edge of 1½in. The mean revolutions of the engines were 249-5 and the boat's mean speed 8-040 knots were 249.5, and the boat's mean speed 8.040 knots per hour. It was boisterous weather when all the boats were tried over the measured mile. All four of the boats were very handsome and buoyant in their appearance when under full steam pressure in running over the measured mile.—" Times."

## STEAM PUMPING ENGINE.

THE very compact little engine, illustrated in the accompanying engraving, has been designed and constructed by Messrs. S. Owens and Co., of Whitefriars, to meet the existing demand for a really efficient and reliable donkey engine; and while no attempt has been made to compete in price with the many and various examples of donkey engines which are at the present time in the market, no pains have been spared to ensure thorough reliability of action, efficiency, and durability. In doing so, those parts of the steam engine which are generally admitted to be essential to its proper working have not been dispensed with, neither have the makers run into that extreme simplicity generally indulged in, the object being simplicity generally indulged in, the object being to produce a serviceable pump, at all times certain in action, at a reasonable cost. We recently visited Messrs. Owens' works, where we found one of these pumps working away in the most satisfactory manner. It had a  $4\frac{1}{2}$ -inch steam cylinder,  $2\frac{1}{4}$ -inch pump cylinder, 6-inch stroke, making 150 strokes per minute, and delivering over 1,200 gallons per hour. The chief novelty in the design of these machines is the arrangement of the valves of the pump, which from their peculiarity, cannot become set fast in working; and, as the valves and seatings are easily removable, they can be readily replaced by a new set, when they become defective by wear, and thus the pump may be restored to its original state of efficiency at a trifling expense. We need scarcely observe that one of the advantages of a double-acting pump is, that a continuous feed to a boiler is maintained, and a regular and constant delivery into a tank is effected, while the duty performed is just double that of a single-action pump of a corresponding size. Seeing several of these pumps in progress, we could not but observe that in their manufacture special attention and care is paid to the fitting and finish of every detailed part, the materials used being of the best quality. The bed plates are planed over their entire surface, the fly-wheels are turned up true on the rims, the cranks are made of wrought iron, both the steam and water cylinders are furnished with metallic pistons, and all the working parts of the pumps are made of the best gun metal. On the whole, we are favourably impressed with Messrs. Owens' latest novelty in the feed pump line, some of which, we may add, are out and doing good

MIDLAND BOILER ASSURANCE COMPANY. HE fourteenth half-yearly meeting of the above association was held last month, when Mr. E. B. Marten presented his report, from which we gather that up to December 31, 1868, there were 2,633 boilers under the care of the company. Only one serious explosion occurred during the year 1868 to any boiler under the company's care, and even this one exploded while the fire was being drawn, in one exploded while the fire was being drawn, in order to execute repair, reported necessary by the company's officers. One or two injuries scarcely to be called explosions have taken place, owing to shortness of water, and when the boilers were under assurance they have been reinstated. During the past year, each of the boilers under the care of the company has been seen at least four times, and more than half the number have been seen inside and in the flues. Many instances might be given where the written reports, sent to owners, have led to the repair or renewal of old or unsafe boilers. Attention has been given to the prevention of smoke with considerable success. Engines continue to be examined with the indicator, with useful results. The company's officers continue to obtain records of with considerable success. Engines continue to be examined with the indicator, with useful results. The company's officers continue to obtain records of boiler explosions, by personal examination of the remains, in order to ascertain what evils to guard against to insure the safety of boilers. Records are given of 45 explosions, by which 57 persons were killed, and 71 injured. The most fatal expiosions have been at iron works, because the boilers stood in the midst of the workmen. The boilers which most frequently exploded were those internally fired, chiefly owing to the want of strengthening rings on the tubes, now proved necessary. Many externally fired boilers exploded because worked for 30 years and more, and so frequently repaired as to make it impossible to estimate their remaining strength. The most frequent cause of explosion has been faulty construction with imperfect material or workmanship, or insufficient stays, but corrosion has also, as usual, been the direct cause of many explosions. The officers of this company have now considerable experience in their psculiar duties, and, knowing where to look for it, are often able to detect mischief and prevent explosion. At the end of the year 1868, 1,103 boilers were under inspection, and 1,530 under assurance, making a total of 2,633, as given above. These boilers were used for the following purposes—1,238 in collieries, 1,156 in iron works. year 1868, 1,103 boilers were under inspection, and 1,530 under assurance, making a total of 2,633, as given above. These boilers were used for the following purposes—1,238 in collieries, 1,156 in iron works, and 239 in mills of various kinds. The boilers were of the following general description:—2,205 fired externally, and 428 fired internally. During the year there have been made 11,900 inspections of boilers, 1,483 of which have been internal, and 1,361 in the flues, and 1,656 reports have been sent to the owners. flues, and 1,656 reports have been sent to the owners.

#### LONDON ASSOCIATION OF FOREMEN ENGINEERS.

ENGINEERS.

IT has been definitely arranged that in future the monthly meetings of this institution shall be held at the City Terminus Hotel, Cannon-street. The first sitting at that place is appointed for Saturday, April 3, at eight p.m., and it will be followed by others regularly throughout the year on the first Saturday in each month, at the same hour. It was expected that Professor Tyndall would have read a paper on the 3rd proximo, but he has, unfortunately, been obliged to postpone it for the present. Under these circumstances, the president, Mr. Newton, of the Mint, will deliver an address having relation to the opening of the new assembly room; and Mr. Robert B. Vinicombe will read a paper on gunpowder machinery, at the April meeting. It is hoped that members, both honorary and ordinary, will attend in large numbers, and will also use freely their privilege of inviting friends interested in the progress of engineering science to be present at this and all other sittings of the Association. The committee are exceedingly anxious that the proceedings of the associated foremen should be shared in by representatives of every class and every department of the engineering profession, so as to widen the influence and increase the value of the institution as much as possible. The newly-acquired assembly room is spacious and well appointed, and in all ways calculated to conduce to the advancement of the society. All that is further essential is the active co-operation of the engineering community generally It may be mentioned that, according to the original and unaltered rules of the Association, employers of engineering labour are admitted to any or all of its meetings on the presentation of their cards, although they may not be enrolled as honorary members. They are, however, always welcome visitors. TT has been definitely arranged that in future the

# DIVIDING AND GEAR CUTTING MACHINERY.\*

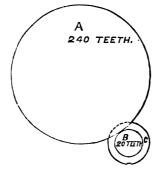

GREAT deal of time, money, ingenuity, and nice A workmanship have been expended in the production of machinery for dividing the circle into equal parts. Among the early productions of this class was that of Jesse Ramsden, an intelligent mechanist, who, about one hundred years ago, was

\* " F. G. W," in the American Railway Times.

employed by the Commissioners of Longitude in dividing the arcs of sextants, and quadrants, and instructing others in the use of his machine. His machine consisted of a large bell-metal dividing wheel, containing 2,160 teeth in its periphery, in which a steel worm worked. In its details this machine was quite elaborate and complex, and required chine was quite elaborate and complex, and required much painstaking and ingenuity in its construction. Some of the gear cutting machines of the present time work with a worm, upon the same principle of the Ramsden machine. The chief objection to the worm machine is, great wear of the worm and teeth of the wheel; the worm often requires to be revolved many times for each tooth that is cut.

The machine most extensively used for cutting gears is that with a perforated wheel. The perforations are made with a drill in concentric circles on the face of the wheel, and it requires the most careful and skilful manipulation to fit up and perforations. forate these wheels; and then it requires great care in the use of this machine in setting the steel point in the use of this machine in setting the steel point in the perforations, otherwise the holes will, in time, become so worn as to cause imperfect work. The operator should be careful and not let the point down until the hole is exactly beneath the point, else there will be a tendency to wear the holes on

All things considered, the machine that works with All things considered, the machine that works with gear and pinion is the most serviceable and the most expeditions in operation. I have noticed that most of the new machines made in Worcester are of this class. The dividing part of this machine consists of a gear wheel, A; the pinion, B; and auxiliary wheel, C. The main wheel, A, may contain any number of teeth that is an exact multiple of some smaller numbers, and may be of any diameter proportionate to the size of the machine required. A multiple of 12 and a diameter of from 2 ft. to 4 ft. are the proportions adopted here by mechinists ft. are the proportions adopted here by machinists. The number of teeth in the main wheel,  $\Lambda$ , must be exactly divisible by the number of teeth in the pinion, without a remainder. A number of auxiliary wheels, C, are required in order to produce the great

variety of divisions required by the these wheels are made exactly alike in diameter and thickness, and are interchangeable, so as to be used, these wheels are made exactly alike in diameter and thickness, and are interchangeable, so as to be used, one at a time, in connection with the pinion, B. They must be so connected to the pinion as to revolve with it, without the possibility of the least slip. These wheels are divided, on their periphery, into various numbers of equal parts (no two alike), by notches deep enough to engage a pawl, by which the wheel is turned. Now, if the main wheel, A, contains 240 teeth, it is evident that any number which divides 240 without a remaider, may be produced without the use of the pinion and auxiliary wheels, as 2, 3, 4, 5, 6, 8, 10, 12, 15, 10, 20, 24, 30, 40, 48, 60, 80, 120, and 240. But it is for the production of the intervening numbers that the agency of the pinion and auxiliaries are required. If, for instance, a wheel with 27 teeth is wanted, it is evident that the main wheel, A, must be moved 1-27th of a revolution for each tooth; hence the auxiliary must contain such a number of notches or divisions as will produce this result by moving and setting it 27 times; therefore, the auxiliary wheel, C, contains 27 teeth, or some number that is a multiple or measure of 27, as 9, 54.

A rule which can be easily remembered for answering all each may be eastly them.

A rule which can be easily remembered for answering all cases may be stated thus:—Divide the number of teeth in the main wheel, A, by the number of teeth in the main wheel, A, by the number of teeth in the pinion, B, and use the quotient as a numerator of a fraction, the denominator of which is the number of teeth required to be cut. This fraction will express the motion to be given to the pinion for each tooth. Applying this rule to the case in hand, we have 240 divided by 20 equal 12: then as 27 is the number of teeth to be cut, 12-27 of a revolution of the pinion is required for each tooth; this fraction reduced equals 4-9; hence, if the auxiliary contains 9 notches, four of them must be taken in each movement for a tooth; if it contains 27 notches, 12 of them must be used for each tooth; if it contains 54 teeth, 24 of them mus be taken for each tooth. &c. If 360 teeth or divisions are wanted, 12-360 or 1-30th of a revolution of the pinion will be necessary for each tooth or division; hence an auxiliary wheel with thirty notches or divisions will be needed, or such a number as can  $\Lambda$  rule which can be easily remembered for answer-

the ones they are calculated for. The one with 30 notches, for instance, may be used for 180, 120, 72, 60, &c., and many more.

#### STEAM v. HORSE POWER.

A T the last monthly meeting of the Highland and Agricultural Society, the subject for discussion was the comparative advantages and cost of steam and horse power or hand labour—1. With reference to the working of land in a high state of cultivation; and 2. With reference to improvable land. The president, the Marquis of Tweeddale, opened the discussion by reading a paper, in which he detailed his experience in the cultivation of his farm of Yester. He tried ploughing with ordinary ploughs drawn by horses, then ploughs of his own invention in which the mould-board was convex, instead of the old-fashioned concave mould-board. He next tried oxen in drawing the ploughs, but they were too slow, and the shape of their feet unfitted them for walking on the pulverized soil. He also tried steampower, but the stones caused breakages, and any contrivance to disengage the power of steam for the machinery when it met an obstacle proved a failure. The noble president also gave his experience as to his cultivation of the farm of Newall, and on T the last monthly meeting of the Highland and fine machine.

The noble president also gave insexperiones as to his cultivation of the farm of Newall, and on the whole he found horse-power best suited in the machine of his land; and ploughing with a pair the whole he found horse-power pest suited in the improvement of his land; and ploughing with a pair of horses from 12in. to 18in, deep cost him 12s, per acre, or using three horses to the plough it cost him 14s, 5d, per acre. Mr. George Hope, Fentonbarns, spoke highly of the noble president's paper, and stated that it was the first time in his experience that he had heard a president of their security give a and stated that it was the first time in his experience that he had heard a president of their society give a sound and practical lesson to agriculturists. He then proceeded to read a paper, in which he related his experience in cultivating his farm with horse and steam-power. He spoke most favourably of steam-power, by means of which every acre of his farm had been cultivated to his wish, and every crop had been sown in good time, which all practical men knew to be of creat importance in a necuniary crop had been sown in good time, which all practical men knew to be of great importance in a pecuniary point of view. The cost of steam ploughing was 8s. 0½d, per acre, and 6s. 4d, per acre for grubbing, Mr. Greig, Kincardine, spoke in favour of the steam cultivator, and read a great number of letters from farmers in Kincardineshire, who stated that by the use of the steam plough better crops had been obtained, and the subsoil loosened and broken up without being brought to the surface, which could not be done with horse-power. not be done with horse-power.

# Mogal Intelligence.

ROLLS COURT. . March 24. (Before the Master of the Rolls.)

CROSSLEY V. DIXON.
THIS suit was instituted by the firm of John Crossley and Sons, now Crossley and Sons (Limited), the well-known carpet manufacturers (Limited), the well-known carpet manufacturers of Halifax, in order to obtain a declaration that the Dixons, who are carpet manufacturers at Kidderminster, are liable to pay a royalty on certain looms worked by them, and obtained from the plaintiffs, for a period of about a year prior to the 6th of Daganher 1866 during which period the 9th of December, 1866, during which period any of the improvements incorporated in the looms were protected by patents belonging to the plaintiff. The patents in question, the last of which expired on the 9th of December, 1866, were two of a person named Johnson, which bore date March 8, 1852, and December 7, 1852, and also two of a person named Collins, which bore date October 1, 1852, and December 9, 1852, for improvements in the manufacture of Brussels and velvet pile carpets. The defendants' answer to the suit was that in a former suit of "Crossley v. the suit was that in a former suit of "Crossley v. Dixon" it had been ascertained and determined what patents were then subsisting and worked by the defendants, and that these patents had all expired by the time when the present suit was instituted, and that the investigations made in the former suit, and confirmed by the Chief Clerk's certificate, showed that what was included in the looms sold to the defendants did not include the patents which were now insisted upon by the plaintiffs; and, secondly, if the first contention failed, then that the looms did not invade the inventions contained in and protected by the plaintiffs' patents.
Mr. Grove, Q.C., Sir Richard Baggallay, Q.C.,

and Mr. Cracknall appeared for the plaintiffs; and Sir Roundell Palmer, Q.C., Mr. Jessel, Q.C., Mr. Speed, and Mr. Theodore Aston for the de-

His LORDSHIP thought that the former suit did not dispose of the question. The point at issue in that case was whether certain machines of Messrs. division: nence an auxinary wheelwith thirty notenes or divisions will be needed, or such a number as can be measured by 30, as 60, 90, &c. These auxiliary Sharp, Stewart, and Co., which were sold to the wheels are applicable to many other numbers than defendant Dixon, included any of John Crossley

and Son's patented inventions. It was true that the plaintiffs were the same, and the Dixons were defendants, but they had no interest in the matter, which was, in truth, solely a contest be-tween John Crossley and Sons and Sharp, Stewart, and Co., and the latter firm defended the suit from first to last. Accordingly, though the two in-quiries were nominally the same, they were so only as between Crossley and Sharp, the first being what inventions were included in and protected by Crossley's patents, and the second which of the inventions, if any, were made use of in Sharp's machines. The real question at issue in the present suit was only a collateral one, and was not pursued in the former suit; and his Lordship was, therefore, of opinion that the second question did arise, and that it was his duty to determine whether the looms supplied to the defendant Dixon did include the said patent, or any and which of them. His Lordship had permitted the originate correctly and found himself. rused the evidence carefully, and found himself unable to determine this question without seeing the machines, and having them explained to him by gentlemen conversant with the matter. If the parties would consent to be bound by his opinion, after examining the machine and having the matter explained to him by two gentlemen, one on each side, he would determine it. If not, he should send an issue to a jury, who should decide whether any, and, if any, which of the inventions protected by the patents was included in the machines supplied by the plaintiffs to the defendants

# PANAMA HATS-WHAT THEY ARE MADE FROM, AND HOW.

MADE FROM, AND HOW.

THE screw pines are natives of tropical regions; are abundant in the islands of the Indian Archipelago, and in most of the tropical islands of the Old World, but rare in America; the section Cyclanthese, on the contrary, being exclusively confined to that continent. This order is divided into two sections, the first of which called Pandanse, and the second Cyclanthese. Each of the sections contain several genera, some of which contain several species. The Carludovica is a small genus of the second section of the order. Of this genus the species called by botanists Carludovica Palmata, is the most valuable and interesting; it is the plant from whose leaves the celebrated Panama hats are made. Dr. Seeman, a celebrated South American traveler, states that the

Interesting; it is the plant from whose leaves the celebrated Panama hats are made. Dr. Seeman, a celebrated South American traveler, states that the leaves of this plant are from 6ft. to 14ft. high, and their lamina about 4ft. across. In the Isthmus the plant is called Portorico, and also Jipijapa, but the last name is the most common, and is diffused all along the coast as far as Peru and Chill; while in Ecuador a whole district derives its name from it.

The Jipijapa is common in Panama and Darien, especially in half shady places; but its geographical range is by no means confined to them. It is found all along the western shores of New Grenada and Ecuador; and it has been found even at Salango, where, however, it seems to reach its most southern limit, thus extending over 12deg, of latitude from the tenth N. to the second S. The Jipijapa, or Panama hats, are principally manufactured in Veraguas and Western Panama; not all, however, known in commerce by that name are plaited in the Isthmus; by far the greater proportion is made at

Pannam hats, are principally manufactured in Veraguas and Western Pannam; not all, however, known in commerce by that name are plaited in the Ishmus; by far the greater proportion is made at Manta, Monte Christi, and other parts of Ecuador. The hats are worn almost in the whole American, Continent and the West Indies, and would probably be equally used in Europe, did not their high price varying from 2 to 150 dollars, prevent their importation. They 2 no distinguished from all others by consisting or single piece, and by their lighting that the property of the property protected. The process of making these plants is as follows:

## HORSE POWER.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—When Watt gave us a nominal measure of power, he invented a very good standard—one that defied steam horse dealers to sell an engine for more than its real commercial value. The calculation was simple, and answered, and answers yet the purpose for which it was framed, namely, that the purchaser could not mistake in buying his engine, and that the dealer rested satisfied that he had given the value for money received. I am sorry to see that some advocate an entirely new method, namely, an indicated measure, or a foot-pound standard, for commercial transactions. This measure is advanced, I am happy to say, by non-manufacturers. Were it introduced, what would follow? Simply this: that a certain size of cylinder, length of stroke, &c., &c., could be sold for a variety of powers. The first, we will say, the real value of the machine, the steam, is cut off at one quarter of the stroke. Cutting off at three quarters of the stroke, the power is greatly increased, and consequently a much larger sum would be demanded for the engine. I am merely treating with those dealers who sell engines independently from the boiler. It is quite clear that such a system is not a fair measure. If there is any alteration required, it simply consists in fairly fixing a higher steam standard and raising the engine to

of life I am thoroughly convinced that many good suggestions have emanated from civilians as regards suggestions have emanated from civilians as regards modern artillery. I, therefore, beg leave, through your magazine, to place before the authorities and the general public my opinion that the time has come when we must house our guns, and likewise introduce a very different mode of defence. Some time back, you gave my description of a floating dock and battery combined. Since then, I have considered the practicability of land forts on the same principle, namely, presenting the smallest point of attack by the end-on mode of warfare. My original idea showed a fort constructed of stonepoint of attack by the end-on mode of warfare. My original idea showed a fort constructed of stone-work protected with iron plating, covered over with a bank of earthwork. This would be somewhat expensive; but I consider such a fort formed internally with strong brick arches, covered entirely with a deep mound of earth, and strongly protected at the embrasures only, is not only the strongest structure that can be made, but likewise the cheapest. cheapest.

cheapest.

It may be asked, why do I not put my ideas before the proper authorities? My answer is, as I stated before, I am no soldier, and I prefer to state my opinion boldly and openly through the press of the profession. We have long since passed the time when such ideas can remain for any length of time secrets; conservatism on such subjects has become a dead letter. And, in conclusion, I should feel obliged if any of your military readers would discuss this subject through your paper; and, Sir, I am confident that they will come to the conclusion that such a peaceful tilt of arms constitutes England's strength.—I am, Sir, yours, &c.,

JOHN G. WINTON.

13, Gladstone-street, March 23.

13, Gladstone-street, March 23.

# Habal, Military, and Gunnety Items.

THE death, at Passy, is announced of General Jomini, the well-known writer on military tactics, at the advanced age of 90.

IT is rumoured that Major-General Simmons, C.B. Royal Engineers, has been selected to fill the appointment of Lieutenant-Governor of the Royal Military Academy, Woolwich.

THE new steamer, "City of Brooklyn," on her arrival at New York from Liverpool, was voted a suit of colours by the Brooklyn City Government, in honour of her name.

THE French army has just lost one of its most gallant officers by the death, after only two or three days' illness, of General O'Malley. He was the son of one of the Irish emigrants of '98, who entered the French service under the Consulate. The late General was in his 75th year.

The report of the committee on the contracts with the Cunard Company and the Imman Steamship Company, for the conveyance of mails to North America, was presented to the House of Commons on Tuesday week. It condemns the arrangement, but suggests that it should be continued, though for shorter tarm of variety than that represed by the a shorter term of years than that proposed by the agreement as it now stands.

According to the last statement issued by the Bureau ACCORDING to the last statement issued by the Dureau Veritas of Paris, the number of ships reported as totally lost in the month of February last is 238, of which 115 were English, 24 French, 22 American, 19 Italian, 15 North German, 6 Danish, 6 Spanish, and 31 of various other nationalities. The number of total losses during the corresponding month of 1868 was 212; of 1867, 224; and of 1866, 268.

vessels are of the first rate, 2,400 tons and upwards; 37 of the second rate, 1,200 to 2,400 tons; 76 of the third rate, 600 to 1,200 tons; and 58 of the fourth rate, under 600 tons. Fifty-two of these vessels are ironcled, carrying 129 guns; 95 screw steamers, 938 guns; 28 paddlewheel steamers, 199 guns; and 31 sailing vessels, 477 guns. The European squadron has 5 ships; the Asiatic, 9; the North Atlantic, 6; the South Atlantic, 5; the North Pacific, 8; and the South Pacific, 6. vessels are of the first rate, 2,400 tons and upwards

THE 450-pounder American smooth-bore gun was fired on Wednesday against the Plymouth casemate at Shoeburyness; the English shot proving something superior to the American spherical projectiles. The vibration of the blows of these heavy jectiles. The vibration of the blows of these heavy shot produced such a flaking of the iron armour as would tend rapidly to the disintegration of even this thick structure of solid iron. Colonel Shaw's muzzle-pivoting carriage for the 18-ton Fraser rifled gun was also further successfully tested with 13 rounds of 400-pounder shot fired with 60lb. charges. Want of space compels us to defer details of these experiments until next week.

# Miscellanea.

THE works of the railway between Athens and the Pirmus are now nearly completed, and will pro-bably be opened for traffic early in the present month.

SAN FRANCISCO is in a fever of excitement at present, over the gold discoveries, at the White Pine Mines. Fifty-six companies have been organized in that city since the lat of March to work leads in the White Pine region,

THE population of France, according to the "Bulletin des Lois," during the last five quinquennial periods, was as follows:—1846, 35,400,486; 1851, 35,783,206; 1856, 36,039,364; 1861, 87,382,225; and 1866, 38,067,094.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending March 27, was 5,377. Total number since the opening of the Museum, free daily (May 12, 1858), 1,527,444.

WE have to record the death of one of our oldest and most respected citizens, Mr. Thomas Brown, of Ludgate-hill. For many years he was a partner in the well-known firm of Messrs. Longman, Brown, Green, and Co., Paternoster-row, from which he retired some eight or nine years since.

A NEW regulation has just been issued by the trustees of the British Museum requiring that students frequenting the galleries, for the purpose of copying objects of art, natural history, &c., should on each visit inscribe their names in books provided to receive their signatures, and now placed in the entrance-hall of the institution with that view.

A roo whistle, recently erected on Cape Fourcher, A FOG whistie, recently erected on Cape Fourener, Yarmouth Harbour, Nova Scotia, is said to be the most powerful signal in North America, and can be heard fifteen miles in calm weather; in stormy weather, five to eight miles; with the wind, twenty-five miles; against the wind, five to eight miles. It has been heard inland with the wind twenty-five to thirty miles. thirty miles.

THE King of Bavaria has decided that there shall The King of Bavaria has decided that there shall be a universal Fine Art Exhibition held this year at Munich, in the Crystal Palace of that city; it is to take place after the closing of the Paris salon, in June, in order to give French artists an opportunity of presenting their works. The prestige of Munich in matters of artis expected to give additional interest to this exhibition. to this exhibition.

THE number of visitors to the South Kensington THE number of visitors to the South Kensington Museum during the week ending March 27, 1869, wass—on Monday, Tuesday, and Saturday (free) from 10 a.m. to 10 p.m., 16,521; Meyrick and other galleries, 3,848; on Wednesday, and Thursday, cadmission 6d.), from 10 a.m. till 5 p.m., 1,430; Meyrick and other galleries, 1,815; total, 21,993. Average of corresponding week in former years, 11,070. Total from opening of Museum, 8,264,270.

WHILE the sexton of the parish church of Padstow While the sexton of the parish church of Padstow, Cornwall, was recently digging in the churchyard, he came upon an upright piece of granite, fixed in a piece of much larger size, which seemed to form the lower part of a very ancient piece of carved work. The footpiece was a large, flat, and irregular-sided granite stone, 8ft. long, and 5ft. wide, weighing nearly three tons. Padstow Church was built more than 1,000 years ago.

It is estimated that 1,000 persons are employed in Birmingham in the manufacture of pins, hair-pins, hooks, eyes, thimbles, and eyelets. Messrs. Edelsten and Williams alone use three tons of wire weekly in pinmaking, and Messrs. Eridge and Merrett, C. Iles, Phipson and Son, and other makers, would probably augment the total consumption of brass wire to 12 tons per week. At a moderate estimate, the number of pins manufactured weekly in Birmingham exceeds of pins manufactured weekly in Birmingham exceeds 200,000,000.

A LARGE number of gold English coins of the reigns of Edward III. and Henry VI., and French coins of the reigns of one of the Charles and Louis of France, the reigns of one of the Charles and Louis of France, were recently picked up at the Blackpool sands, near Dartmouth. They are nearly all in a good state of preservation. It is supposed that the coins formed part of a box of specie on board a vessel which had become a wreck in this locality, and that they became embedded in the sand, from which they have now been washed out. now been washed out.

MESSRS. MERRYWEATHER AND SONS have just forwarded from their works one of their celebrated Paxton fire engines to Tredegar Park, the seat of Lord Tredegar. The engine is handsomely finished, and upon each side of the panels of the horsebox is and upon each side of the panels of the horsebox is the coronet and monogram, and the words "Tredegar Park" in gold letters. The engine in question is similar to several recently supplied to the Metropolitan Fire Brigade, and is capable of discharging 100 gallons of water per minute, to a height of 120ft., two jets of water being projected through the delivery hoses simultaneously.

THE second term of 1869 of the South London Working Men's College, 91, Blackfriars-road, will begin on Monday next, when Sir John Lubbock, Bart., F.R.S., will preside at a general meeting of the members and friends of the college, at 8-30 p.m. The classes and schools will also reopen on the same day. Lectures will delivered, by Dr. Cobbold, F.R.S., on Monday, April 5, and by T. B. Payne, Esq., M.A., on Thursday, April 8. Among the new classes are, one in mechanics, under Mr. C. T. Mitchell, M.A.; one by Mr. A. D. Tyssen, B.A., in Greck history; and an advanced night school, under Mr. W. Rossiter, F.R.A.S. THE second term of 1869 of the South London

There seems little reason to doubt that the yield of Australasian gold is on the increase, this result being attributable to the discovery of several new fields. In 1868 we received Australasian gold to the value of £6,989,594, as compared with £5,801,207 in 1867, £6,839,674 in 1865, £5,051,170 in 1865, £2,636,971 in 1864, £5,995,368 in 1863, £6,704,753 in 1862, £6,331,225 in 1861, £6,719,000 in 1860, and £8,624,566 in 1859. It will be seen that the total receipts of Australasian gold for the 10 years ending 1868 inclusive were altogether £61,713,528, 1868 having made the largest yearly contribution to this aggregate, with the exception of 1859. THERE seems little reason to doubt that the

Two or three interesting discoveries have been made in the course of the excavations in the Briggate, Leeds. A pit dug out of the solid rock, to the depth of 22ft. was come at towards the end of last week by the workmen. It was filled with black soil of a rich character, and a large number of bones were disinterred from the bottom of the pit. bones were disinterred from the bottom of the pit. Some ancient specimens of crockery ware were also found in the pit, and are pronounced by good authorities to have been produced at least four centuries ago. They consist of three drinking cups and two lamps such as those formerly used by monks; a couple of antiquated looking pipes, and a key of somewhat peculiar workmanship, are amongst the other articles taken from the pit.

The imports of gold into the United Kingdom in January were on a comparatively restricted scale, having been £601,071 as compared with £2,117,760 in January, 1868, and £779,470 in January, 1867. In these totals the imports from Australasia figured for only £292,259 as compared with £410,092 in January, 1868, and £451,910 in January, 1867. The United States, which delivered to us gold to the value of £1,306,925 in January, 1868, only sent us £75,746 in January, 1869. The exports of gold from the United Kingdom amounted in January to £483,461 as compared with £1,578,070 in January, 1868, and £754,216 in January, 1867. In these totals the exports of gold to France figured for £214,773, £1,485,860, and £707,426 respectively. THE imports of gold into the United Kingdom

A LOCKSMITH, of Mulhouse, named Herrenschmidt claims to have discovered a mixture which is said to give to the commonest steel the grain and the to give to the commonest steel the grain and the temper of the finest cast metal, and, moreover, to have the power of bringing back the original quality of steel which has been burnt. The mixture is composed as follows:—With 16 litres of disis composed as follows:—With 16 litres of distilled water mix one kilogramme of hydrochloric acid, 19 grammes of nitric acid at 36deg., 21 grammes of sulphate of zinc, and 100 grammes of tripoli. In this mixture is to be placed a piece of cast iron of the first fusion, weighing 100 grammes; when the acid mixture has acted on the iron for 24 hours, the composition is ready for use in the ordinary way, and it remains effective till it is all mach.

THE project of establishing through the valley of the Garonne (France) a canal for large navigation to connect the ocean to the Mediterranean, has been to consect the ocean to the meditorranean, has been often mooted; but there is now a new plan for this undertaking, under the auspices of M. Staal de Magnoncourt, late peer of France. The proposed canal is to admit not only merchant ships of the heaviest toppes but also men of war and canal is to admit not only merchant ships of the heaviest tonnage, but also men of war and transatlantic steamers. A port is to be established in the Gironde, just below Bordeaux, and another on the Mediterranean. The cost of the scheme is estimated at 442,000,000f., and the cutting of

the canal would occupy six years. The plan, if carried out, will materially shorten the navigable communication between England, the North of Europe, and India, for it will, in fact, be a continuation of the Suez Canal.

# Patents for Jubentions.

## ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES-2955, 2862, 2868, 2882 BUILDINGS AND BUILDING MATERIALS-2856, 2860, 2861, 2873

2873
CHEMISTRY AND PHOTOGRAPHY—2805, 2820, 2881
CULTIVATION OF THE SOIL, including agricultural implements and machines.—2858, 2873, 2879, 2883
ELECTRICAL APPARATUS—2844, 2854
FIBROUS FABRICS, including machinery for treating fibrapulp, paper, &c.—2821, 2824, 2837, 2848, 2872, 2884, 2895
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2817, 2818, 2822, 2828, 2839, 2846

FURNITURE AND APPAREL, including household utensils, URNITURE AND APPAREI, including household utensils, time-keepers, jewellery, musical instrumenta, &c.—2804, 2812, 2815, 2829, 2830, 2835, 2836, 2840, 2841, 2842, 2843, 2850, 2859, 2874, 2875, 2887, 2889, 2814, 2845, 2852, 2862, 2866

LIGHTING, HEATING, AND VENTILATING-2811, 2826, 2832,

LIGHTING, HEATING, AND VENTILATING—2011, 2020, 2002, 2004, 2834, 2867, 2869, 2886, 2888, 2891

METALS, including apperatus for their manufacture—2810, 2816, 2819, 2825, 2844, 2856

MISCELLANEOUS—2806, 2807, 2813, 2827, 2833, 2838, 2847, 2849, 2851, 2853, 2857, 2867, 2870, 2880, 2833, 2890, 2833, 2890, 2833, 2890, 2833, 2890, 2833, 2890, 2833, 2830, 2830, 2833, 2830, 2833, 2830, 283

2894
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2876, 2878
SHIPS AND BOATS, including their fittings—2825, 2864, 2871, 2877
STEAM ENGINES—2831
WARFARE—2865, 2885, 2892

2804 B. GARDINER and T. H. FAULKNER, Bradford. Umbreilas and parasols. Dated September 11, 1868.

The patentees produce a new fabric suitable for covering the frames from the fibre known as china grass, by dyeing the grass in the state of fibre and afterwards weaving it into a fabric.—Patent abandoned.

weaving it into a fabric.—Patent abandoned.

2805 G. Bischop, Allee, Bonn, Prussia. Precipitation and separation of copper. Dated September 11, 1868.

The precipitation is effected in apparatus consisting of a large wooden cask suspended horizontally on axes supported in bearings on suitable standards. The cask has in its interior four or other number of longitudinal partitions extending radially from the circumference towards the centre. Spongy from and cupreous liquor having been introduced into the cask, an intimate mixture is effected without any caking of the contents by turning the cask slowly on its axis.—Patent completed.

2806 I. Roperts View Willey states E. G. Western

the cask slowly on its axis.—Patent completed.

2806 J. Roberts, King William-street, E.C. Horse shoes.
Dated September 11, 1868.
This consists in forming the outer part or case of a portable stove of two pieces of sheet metal of the same shape, but differing in size, the outer piece of metal being larger round than the inner piece, so as to leave space between the two pieces. The outer piece is formed perforated, and the inner piece solid, and the space between these two pieces is filled with loose or granulated terra-cotta or other similar suitable substance or material.—Patent completed.

2807 J. ROBERTS, King William-street, E.C. Horse shoes. Dated September 11, 1868.

The patentee employs a piece of leather or other material riveted to the turned up edges of a flat plate of sheet metal, and to this piece of metal an iron shoe of the ordinary kind is riveted or otherwise securely fixed.—Patent abandoned.

the ordinary kind is riveted or otherwise securely fixed.—Patent abandoned.

2808 G. Bowrr and W. Hollingshed, St. Neots. Gas engines. Dated September 11, 1868.

The engine consists of a framework carrying two cylinders placed diagonally, and at right angles to each other; these cylinders are arranged so as to oscillate on hollow trunnions, and both piston rods are attached to the same crank pin. On one side of each cylinder, and having the axis of oscillation passing through it, there is fitted a valve box with a cover and slide valve, and on the face of the cover of the valve box there is attached the hollow trunnion. The trunnion on the opposite side of the cylinder is attached direct to it. Each cylinder is provided with a jacket or outer case for the purpose of passing a stream of water round it to keep it cool. Within the hollow trunnions are fitted internal tubes or casings having compartments arranged in them; these internal tubes or casings are turned to fit accurately and truly the internal casings are held in position by a bracket and set serew bolted on to the framework of the engine, thus preventing them from oscillating or vibrating with the trunnions and cylinders. The explosion of the mixture of gas and air is effected at one end of each cylinder, only the down stroke being performed by the pressure of the atmosphers acting on a partial vacuum produced under the piston by the exploded gases.—Patent completed.

or other support for such article or matter, being connected with or formed on the arm. The other arm of the lever carries or is formed with a counterpoise. The lever or beam works or oscillates on the knife edge or edges, and it or its axis is connected with appliances which actuate a pointer travelling over a graduated dial to indicate the weight. When an article or matter to be weighted is placed in the tray or other support formed on or connected with one arm of the lever, the counterpoise arm swerves from the perpendicular, and by the arrangements in connection with it the lever or beam acts upon the property which indicates the weight on the dial pointer which indicates the weight on the dial. Patent completed.

2810 H. B. Woodcock, Low Moor. New manufacture of metal. Dated September 12, 1868.

This consists in the employment of steel bars in the puddling furnace during the process of puddling pig or refined metal into wrought iron. The steel bars are cut into small pieces, and their quantity or proportion varies from about 1-12th to 1-3rd in weight of the mass to be mixed, according to the purpose and degree of hardness and malleability required. The mass is then boiled, puddled, and worked together by the puddler in the ordinary process of puddling.—Patent completed.

2811 C. TURNER, Preston. Furnaces. Dated September 12, 1868.
This consists in perforating or forming apertures or holes in the front of the furnace plate above the doorway, which are capable of being closed by dampers or shutters, and through which, when open, a current of air is admitted, which is caused to strike or impinge against a "buffer" or inclined plate projecting from a point above the apertures into the furnace, terminating a few inches above the bars or grate, the dimensions of such bars longitudinally being reduced to about two-thirds the length of the ordinary firebars, the remaining one-third being built up with firebricks.—Patent abandoned.

2812 A. W. RODGER, Stewarton, N.B. Caps or bonnets.

2812 A. W. RODGER. Stewarton, N.B. Caps or bonnets. Dated September 12, 1868.

This consists in the insertion of a plece or pieces of elastic or other suitable expanding and contracting material at one or more places round the mouth, or that part of the cap or bonnet which fits the head.—Patent abandoned

doned.

2813 F. WARNER, Jewin-crescent, E.C. Wells and pumps.
Dated September 12, 1868.

The patentee bores or forms in the earth by means of an augur or other tool a hole, several inches in diameter, in the usual way. He lines the hole with a metal tube, as he proceeds, to prevent the sides of the hole falling in. He works in this way until the water-bearing stratum is arrived at, and he then puts down the suction pipe of the pump and draws up the outer tube out of the carth, so as to admit of the earth being closely rammed in around the upper part of the suction pipe. When the desired depth is attained, he inserts the suction pipe into the bore hole; the pipe is perforated at its lower end with numerous small holes. In the pump which he employs, the barrel, which has the suction valve at its lower end, is enclosed in an outer chamber of cylindrical or other form, which is closed both at the top and bottom. The suction pipe is connected with this chamber at a point intermediate of its height, so that the lower part of the chamber always contains water, in which the suction valve is immersed.—Patent completed.

2814 E. Turner, Bristol. Packing for visions. &c. Dated

2814 E. TURNER, Bristol. Packing for pistons, &c. Dated

2814 E. TURNER. Bristol. Packing for pistons, &c. Dated September 12, 1868.

The inner bark of the linden or lime tree, with the gummy matters removed from it by bolling in an alkaline solution, is employed. The raw inner bark is bolied by preference in a solution of caustic soda for about four hours, and then washed in water until perfectly clean. It is then dried and carded and made ready for spinning. It may then be used in the same manner as flax is at present employed for packing, by being made into the form of rope or band, and saturated with oil or other lubricating compounds.—Patent completed.

compounds.—Patent completed.

2815 W. R. Lake, Southampton-buildings, W.C. Manufacturing brushs. (A communication.) Dated September 12, 1868.

This relates to the manufacture of brushes in which each tuft or bundle of fibre is secured by a separate wire staple in a perforation formed partly through the brush stock. It consists, first, in combining with the bett or carrying apron for feeding in the bristles or other fibres a divider, which separates the bristles, so as to form them into bunches or tufts. Second, in the construction and operation of fingers, made to spread out laterally to effect the separation of the bristles into tufts, and afterwards to carry or push forward the same. Third, in combining the divider and fingers, so that the fingers are made to lift and release the divider. Fourth, in combining with the fingers a slide, which operates conjointly with, and independently of, the fingers. Fifth, in a combination of devices for operating the fingers. Sixth, in combining with the said fingers and skide punch jaws, a wire cutter, and a staple former. And, lastly, effecting, in an automatic manner, varied adjustments of the brush back, or stock to insure a regular insertion of the bristles.—Patent completed. Patent completed.

2816 J. E. COOMBE and S. G. Greeg, Lombard-street, E.C. Coating iron and steel. Dated September 12, 1868. The patentees apply a priming of varnish, made of lac gum. junjer, or any of the gum resins dissolved in naphtha, pyro-acetic, ether, or spirits, or any menstrum capable of taking them up. This priming is applied directly to the surface of the metal, the latter being first heated by any suitable appliance.—Patent abandoned.

2817 J. COPPARD, Park-street. Mincing meat. Dated September 14, 1863.

This relates to a machine which has a cylinder of iron or other substance, wherein are enclosed one or more rows of fixed knives and a series of rotating propellers. It consists, first, in means for supporting the propeller axle, whereby the machine is constructed with a central delivery, and enabled to support the axle in two or more bearings. Second, in constructing the cylinder so that it may have its delivery nozzle readily attached and detached, and be opened and closed without removing the nozzle. Third, in supporting and securing the knives so that they may be readily removed from the cylinder.—Patent completed.

2818 W. B. LAKE, Southampton-buildings. Substitute

for hair stuffing. (A communication.) Dated September 14

for hair stuffing. (A communication, peace and 1868.

This consists in treating the fibre of the soap plant so as to render it suitable for use as mattress stuffing, &c. The plant is first separated into fibres by means of a picker or other suitable device, after which it is boiled for two hours, more or less, in an alkaline solution consisting of 40 gallons of potash, dissolved in 20 gallons of water, for every 20lb. of fibre. The fibre is then washed in clear cold water, and after being dried is spun or twisted into a rope or cord. It is then steamed for about one hour and again dried and picked by hand, or otherwise, when it is ready for use.—Patent abandoned.

2819 C. E. BROOMAN, 166, Fleet-street, E.C. Metallic lates or blocks. (A communication.) Dated September 14,

This consists in manufacturing metallic plates or blocks by superposing in a metal box a certain number of pieces of sheet iron or steel, tinned, galvanized, or coated with lead, zinc, or other suitable fusible metal or composition. -Patent abandoned.

2820 F. SUBOHM-ULTZEN, Westminster Palace Hotel. Generating carbonic acid. (A communication.) Dated September 14, 1868.

tember 14, 1868.

This consists in a cylindrical vessel made of lead intended for the development of carbonic acid from marble or pure lime, and of another cylindrical vessel, also kept closed, serving for purifying the carbonic acid, and of an open vessel of earthenware, glass, or other material, to receive muriatic acid, which should be mixed with water, in the proportion of about three parts of muriatic acid to four parts of water.—Patent abandoned.

2821 C. E. POMMER, Paris. Improved size for paper. Dated September 14, 1868.

This consists in a solution of sulphate of alumina mixed with a solution of resinous soap from which a precipitate of the resinate of alumina is obtained. This precipitate when washed, drained, and pressed, forms the size or compound, which is called "aluminocolli."—Patent completed

2823 J. D. PINFOLD, Rugby. Grinding grain. Dated

2823 J. D. PINFOLD, Rugby. Grinding grain. Dated September 14, 1863.
This consists in a number of fixed chilled plates, suitably grooved or roughened with a runner, composed of natural or artificial stone (the stone which answers the best is the Derbyshire grey). The runner stone may be either flat or conical, and works in combination with the tixed chilled and grooved plates. This machine is driven by any convenient prime mover, but it is proposed to transmit the motion through a frictional driving wheel, mounted either upon the spindle of the stone itself or upon the main shaft of the prime mover.—Patent completed.

2824 J. HETHERINGTON, Manchester. Winding yarn

Dated September 14, 1868

Dated September 14, 1868.

This consists in combining with ordinary winding mechanism arrangements for distributing the yarn or thread so that it may be wound into the cop form. The threads are distributed by an oscillating "faller wire," or by a copping rail sliding up and down. In double-sided machines, the two faller wires or copping rails are connected so as to move simultaneously, and motion is imparted thereto by levers, rods, or other suitable mechanism, acted upon by a reciprocating or rotary "shaper," made to reciprocate or rotate by suitable gearing from the drum driving the spindles.—Patent abandoned.

2825 H. J. TURNBULL Sunderland

reciprocate or rotate by suitable gearing from the drum driving the spindles.—Patent abandoned.

2825 H. J. TURNBULL. Sunderland. Preserving submerged iron structures. Dated September 14, 1868.

In order to prevent the oxidation of the iron, it is covered with a composition consisting of gutta-percha and resin disselved in combination with pine varnish. The surface of the metal is first cleaned and prepared, and the composition is mixed and applied in the following manner:—The surface of the iron is first to be made clean by the application of muriatic or other acid brought to a proper consistency by the addition of ivory black and pine varnish. This mixture is then applied with a brush, and after being left upon the iron for a few hours it must be scraped or washed off with water, in which a little soda is dissolved. When the surface of the metal thus prepared has become dry, the anti-oxidizing composition is applied. The anti-fouling composition for preventing the adhesion of barnacles and marine vegetation to the surface of iron or other submerged material is made by dissolving 40z. of phosphorus in 160z. of bi-sulphuret of carbon and 20z. of absolute vegetable naphtha spirit. Then 21b. of shellac and 20z. of gum benzone are dissolved in absolute vegetable naphtha spirit, bi-sulphuret of carbon, or other solvent, to the consistency of thick paint, and the solution of phosphorus is added thereto.—Patent completed. completed.

completed.

2826 J. FENWICK. Bedford. Annealing overs and kilns. Dated Soptember 14, 1868.

The oven is provided with two fireplaces (charged alternately with fuel), and the flues therefrom pass over the roof and fulminate in the same chimney. These flues are flue and open the other, thus causing the flame and gases of one fire to pass over the other fire before its exit from the oven. To allow the utilization of the waste heat, flues leading downwards are provided, by which the heated gases, as they leave the heating chamber near the roof, may be conducted to a drying room or elsewhere before being allowed to escape.—Patent abandoned.

2827 J. Hewes Unper Manne street. Chelses. Admeriti-

being allowed to escape.—Patent abandoned.

2827 J. Hewrs, Upper Manor street, Chelsea. Advertising by night or day. Dated September 14, 1868.

Two sets of cylinders or frames, rectangular or polygonal in form, are telescopically arranged with a lantern top, the whole revolving on fixed spindles or masts placed at suitable distances apart; and colling on and off diagonally on their circumferences is a long, broad band having advertisements conspicuously written or printed upon each of its sides, and which is in constant self-acting motion.—Patent abandoned.

2828 A. M. CLAPF, Chancery long. Pressing off and

2828 A. M. CLARK, Chancery-lane. Drawing off and offling liquids. (A communication). Dated September 14,

1868.

This consists in a cock of suitable metal or wood and a bung, through which a tin or india-rubber tube passes. The cock consists of a tube with a tapered end for fitting in the cask, and a cylindrical part provided with several smaller nozzle pipes. At the ends of these nozzle pipes are fitted india-rubber tubes whose internal diameter is from 1-4in. to 1-5in., and whose external diameter is about in, the tubes being rather longer than an ordinary bottle.

The apparatus is further provided with a rack consisting of The apparatus is further provided with a rack consisting of spaces corresponding in number to the nozzles, such spaces serving to compress and close the ends of the india-rubber tubes when it desired to cut off the supply. A bung is driven into the hole in the cask, through which is passed a tin or india-rubber tube having a spiral bore of a diameter of about 1-5in. This pipe projects downwards a little above the cock and determines the level for the tops of the bottles, which are readily brought to the desired height by the screw table; when the liquid reaches this level in the bottles the flow ceases.—Patent completed.

2829 E. VICKERS, Goswell-road. Hats and caps. Dated September 15, 1868.

The material employed is paper, pasteboard, or cloth. It is first covered with a coating of size and water, and then exposed to the influence of artificial heat until it is thoroughly dried; then soaked in or damped with water for several hours, when, after being saturated with soft soap and water, it is blocked into the desired shape.—Patent abandoned.

2830 C. D. ABEL, Southampton-buildings, W.C. Securing buttons. (A communication). Dated September 15, 1868. The shank of the button is formed in the shape of a small open-ended tube having a shoulder a short distance from the end. This shank is placed between two jaws secured together by a spring. One of the jaws is fixed to a table or other object, while the other carries a catch whereby, when the button shank is inserted, the loose jaw is drawn up close to the fixed jaw, so as to hold the shank firmly. A metallic point or piercer is then inserted into the open end of the tube, and that part of the article of dress to which the button is to be secured is forced over such point on the shank of the button, so as to lie close against the before-mentioned shoulder thereon. The point is then removed, and a riveting punch is introduced into the open end of the tube, and is caused by pressure or blows to widen out the tube in such a manner as securely to hold the article of dress between it and the shoulder on the tube.—Patent completed.

2831 M. BENSON, Manchester-square, W. Steam pumping

2831 M. Benson, Manchester-square, W. Steam pumping mechinery. (A communication). Dated September 15,

This consists in constructing a steam engine with a cylinder and piston so suited to each other that the piston will perform the functions of a valve in opening and closing the parts of the inlet and exhaust passages. This is accomplished by making the piston as much longer than the stroke as is required to cover the steam ports at each end and exhaust apertures in the centre of the cylinder lengthways alternately at the same time when in operation.—Patent completed.

2832 E. Sarjant, Birmingham. Manufacture of gas fittings. Dated September 15, 1868.
This consists in connecting or joining together the parts of gas fittings by the process of casting in metal or chill moulds.—Patent completed.

2833 H. JEWETT, Kentish Town. Toy representing game ocks fighting. (A communication). Dated September 15,

This consists in placing on or between blocks of wood a bent wire or wires in the shape of bell crank levers, the ends of each of the under levers being connected to a wire terminating in a ring on either end of the box or tray in which the mechanism is contained; and the ends of the upper levers projecting through the lid or covering of the box or tray, and being inserted in a small tube turning or revolving freely on a pivot passing through the bodies or other convenient part of the fighting cocks.—Patent abandoned.

doned.

2834 C. DE BERGUE, Strand, W.C. Gas cooking stores. Dated September 15, 1868.

This consists in constructing gas cooking stoves with a combustion chamber separate or distinct from the cooking chamber, so as that the grease or droppings from the latter may not fall into it, and so arranged with regard to the admission or entry of fame and air that the fame enters in a number of separate jets, surrounded by a current of highly heated air (free from smoke, smell, and taste of gas), through and from the combustion chamber into the cooking chamber. The latter has a grid within it, and its top or roof is made of a hollow curved form, to reverberate or deflect the heat on to the upper surface of the grid, which lies in one of two positions, either in a horizontal position, about level with the bottom edge of the mouth of the combustion chamber, or in an inclined position, with its upper end near to the top at the said opening—Patent completed.

2835 F. Brady, North Gate, Regent's-park. Sweeping

and opening—Patent completed.

2835 F. Brady, North Gate, Regent's-park. Succeping and excarating machine. Dated September 15, 1868.

The sweeping and elevating machinery is carried on a frame or case, supported on road wheels, and adapted to be fixed to the back of a cart, or other travelling receptacle, for the material collected. An endless chain of sweeping brushes, and an endless elevating apron, to receive the material swept up by the brushes, and deliver it into a cart or receptacle arealso employed. The axes of the back rollers which support the endless chain of brushes are so carried that the brushes may fall into and sweep out all the hollows and inequalities passed over by the machine. The machine is so arranged that by rocking the frame on the main axis through a small are of a circle in one direction, the sweeping and elevating apparatus may be thrown out of gear with the driving wheels, whilst by rocking the frame in the opposite direction, the apparatus may be put into gear therewith.—Patent completed.

2836 J. H. SCHUCHT, Store-street, W.C. Pianofories are

gear therewith.—Patent completed.

2836 J. H. Schucht, Store-street, W.C. Pianoforts and other instruments. Dated September 15, 1868.

Sound boards are constructed artificially of alternate plates of hard and soft material, such as beech and poplar woods. The plates of soft wood, such as poplar, should be a quarter-of-an-inch in thickness, and the plates of hard wood, such as beech, should be thinner, and vary according to their position in the finished sound board, relatively to the scale of the instrument. The plates are glued together, side by side, the plates of soft and hard wood being placed alternately.—Patent completed.

2837 W Campion and G. Hall. Nottingham. Washing

wood being placed alternately.—Patent completed.

2v37 W. Campion and G. Hall, Nottingham. Washing
or bleaching. Dated September 15, 1868.

A pan or other vessel is employed, in which is fixed
a false bottom, perforated with a number of holes. In the
centre of the pan is fixed a pipe of conical form, the larger
end being fixed at the bottom. In the lower part of the
pipe suitable openings are made, and at the upper part
branch pipes or tubes are fixed, having suitable openings
or perforations.—Patent abandoned.

2838 J. EDMONDSON, Manchester. Securing metallic hoops for packing bales. Dated September 15, 1868.

This consists in punching or cutting pieces partly out of each end of the boop, so that apertures are made in the hoop; the pieces which come out of the apertures remain attached to the hoop, and are bent slightly outwards. These are formed in reverse directions at each end of the hoop, so that one series of bent pieces or claws at one end enters the openings at the other, and rice resa, constituting a double holder or fastening, and securing the two ends together.—Patent completed.

2839 G. DAVIES, Lincoln's Inn. Hulling and cleaning coffee, rice, &c. (A communication.)

Dated September 15,

This consists in the combination of a series of adjustable This consists in the combination of a series of adjustable spring strippers, provided with sarrated or roughened serrated faces of metal, and an endless belt or band composed of serrated or roughened metallic plates, and also in the arrangement of a stiff brush and an endless serrated or roughened belt, whereby the processes of hulling and cleansing or polishing the coffee, rice, or other grain may be successfully effected in one and the same machine.—Patent abandoned.

2840 B. MARTIN, Westminster Bridge-road. Cleaning

2840 E. MARTIN, Westminster Bridge-road. Cleaning boots. Dated September 15, 1868.
This is composed chiefly of a shallow box or frame, in which are set on edge any convenient number of strips of vulcanized india-rubber, secured between narrower strips of metal or wood, firmly fixed in the wooden or other box or frame. At each side of the box or frame is a raised brush, with the bristles inwards, serving to brush the sides and edges of the boots or shoes. In some instances where a larger apparatus is required, a double brush is placed in the centre, so that both sides of the boot or shoe may be cleaned at a time.—Patent completed.

2841 A. ROOKES, East-street, W.C. Curtais rings.
Dated September 15, 1868.
This consists in fitting or providing the rings with one or more pulleys, rollers, balls, or circular discs, at a point about diametrically opposite the point of attachment of the curtain hook. As the ring is caused to move along the pole, the pulleys, rollers, balls, or discs rotate on their axes or centres, and thereby diminish the friction and noise.—Patent completed.

noise.—Patent completed.

2842 W. R. LAKE, Southampton-buildings, W.C.
Covering for valls exitings, &c. (A communication.) Dated
September 15, 1868.

This sheets or lamins of wood, which may be cut from
a log by turning, or by any other suitable process, are
taken, and one side of such lumins, paper, pulp, or sheets
of paper, cloth, or other textile fabric, are applied, and the
two materials are closely united by pressure, or by the
intervention of any adhesive substance.—Patent abandoned.

doned.

2843 E. HENSSER, Jewin-crescent. Fastenings for travelling bays. &c. Dated September 15, 1868.

A plate of oval or other shape is mounted on the upper or outer side of the jaw, mouth, frame, flap, or other convenient part of the bag or article to be fastened. This plate is capable of sliding to and fro upon an under or inner plate attached to the article or upon a part of its surface, and carries on the under or inner slide a pin or stud, projecting downwards or inwards through the fixed plate or surface, on which the outer plate slides, and engaging with or being innerted into or being connected with a bolt formed or furnished with hooks, which, when engaged with, effects the fastening.—Patent abandoned.

2844 W. DURHAM. Currie. North Britain. Preserving

engaged with, effects the fastening.—Patent abandoned, 2844 W. DURHAM, Currie, North Britain. Preserving stire webs and strainer plates from corrosion. Dated September 15, 1868.

A plate of zinc or other metal, electro positive to the wire, is immersed in the pulp, as near the wire as convenient, and is connected by strips of copper or other metal to the framework of the machine, so that complete metallic contact is established between the wire and the plate of zinc. The plates of zinc must be supported free from contact with any metallic part of the machine, except through the copper strips.—Patent completed.

2845 R. Horson, West Ham, Punching mechine, Detail

2845 R. Hoddon, West Ham. Punching machine. Dated September 15, 1868.
This consists of a fixed bed for carrying the counter dies, made fast to strong end standards, which support the operating parts of the machine. Turning in bearings, in the upper end of the standards, is a longitudinal driving shaft, which receives motion from any prime mover. This shaft is mounted eccentrically, and is embraced by saddles attached to the upper face of a compound slide, extending from end to end of the machine.—Patent abandoned.

2846 C. Havangard M. V. Harrow, Now York, No.

abandoned.

2846 C. Havard and M. X. Harmony, New York. Preserting meat, &c. Dated September 16, 1868.

This consists in preserving animal or vegetable matters, by coating them with a gelatinous solution, prepared from vegetable matters. This solution or jelly is mixed with warm water, until sufficiently liquid, and bisulphite of lime, or any equivalent substance producing the same effect, is added to it, in order to prevent the solution from becoming sour or decomposing. It is then forced into the meat or other substance.—Patent abandoned.

becoming sour or decomposing. It is then forced into the meat or other substance.—Patent abandoned.

2847 J. Orbin and T. Geer. Little Britain, E.C. Catting book edges. Dated September 16, 1858.

The apparatus is intended for cutting the edges of books in which the edge of the binding or cover is flush with the edge of the binding or cover is flush with the edge of the leaves. The framing of the machine supports in vertical slides the cutter frame, in which the knife is adjustable, by means of two screws actuated by a hand wheel. The knife is made of a rectangular shape, forming three sides of a parallelogram, sharpened at its lower edge, and of a sufficient depth to cut through the required thickness. It is fixed below the cutter frame, in the interior of which is a movable "platen," which is pressed downwards by a lever and weight. The table on which the book to be cut is laid is faced with two adjustable guides, to ensure the proper position of the book beneath the knife. The cutter frame is caused to rise and fall by means of two eccentries, forged on a shaft below the table, and actuated by a spur pinion on the driving shaft; gearing into an internal spur wheel, mounted on one end of the cam shaft. The driving shaft is provided with a fast and a loose pulley for steam power, and with a flywheel and handle for hand power, and the fork for moving the driving strap from one to the other is attached to a sliding bar connected to a weighted lever.—Patent completed,

2848 J. HORROCKS, Ainsworth. Looms for wearing. Dated September 16, 1868.

This consists in easting on or applying to the outer arms of the cranks on the crank shaft a ring disc or plate having a circular flange projecting from its periphery.—Patent abandoned.

Patent abandoned.

2849 F. F. GREENWOOD, Hornsey. Fastenings. Dated September 16, 1968.

The patentee combines the frame of the buckle with the frame or box of a lock, so that the whole forms one piece. Beyond and raised above that part of the buckle which receives the free end of the tongue when closed down, he forms a bow-shaped bar or loop, or he makes a hole in that part of the buckle to receive the tongue at pleasure. He forms the base of the tongue upon the bolt of the lock. When the bolt tongue is discharged from the lock, he thrusts the free end under the bow-shaped bar. The protusion and withdrawal of the bolt tongue may be accomplished either by the use of a separate key or by means of the mechanism of the lock buckle itself.—Patent completed.

pleted.

2850 G. R. Samson, Wells street, W. Pianofortes. Dated September 16, 1868.

This consists in a new mode of constructing that portion of pianofortes to which the strings or wires are attached. The strings are attached to a tuning pin which passes quite through the wrest plank, every pin having two holes, one in front of wrest plank, and the other at the back. The wire is then attached to one or other end of the pin, and is brought down and passed under a bridge at the bottom of the sound board. It is then brought up and attached to the other end of tuning pin.—Patent abandoned.

2851 J. WALMSLEY, Preston. Communicating in railway trains. Dated September 16, 1888.

Speaking tubes or tubes for the conveyance of vocal sounds are formed in sections, the section fitted to one sounds are formed in sections, the section fitted to one carriage being formed preferably of a metal tube, and being connected to the section of the adjoining carriage by means of flexible tubes. The ends of the metal tubes are fitted with pertions of unions or couplings, and the ends of the flexible tubes are fitted with the other portions of the couplings, so that the various sections may be coupled together throughout the whole or any portion of a train.—Patent abandoned.

of a train.—Patent abandoned.

2852 H. MARRIAN, King's Heath. Weighing machines.
Dated September 16, 1868.
This relates to platform weighing machines. The weight bar is made in two parts, the upper part or bar being hooked or attached to the machine, and the lower part or bar carrying the weights, the bars being connected together by a spring. When the weights are placed upon the lower bar, the spring is made to change its figure, and to cause an index finger to traverse a divided scale, and to indicate thereon the amount of the weights used.—Patent abandoned. abandoned.

abandoned.

2853 J. DE MASY, Brussels. Holding and withdrawing tickets. Dated September 16, 1868.

The case consists of a box having a series of vertical divisions dividing it into compartments in which piles of the tickets are placed. The front of each compartment is open so as to exhibit the edges of the tickets, the openings being of insufficient width to permit of the tickets passing out by a horizontal motion, except at the bottom, where the openings are wide enough to permit two tickets to pass out. In the bottom of each compartment is a slot, and underneath each compartment is a slide, sliding closely against the bottom. On this slide is a projection which passes through the slot in the bottom of the case, the said projection having shoulders which stand above the bottom of the case. The front end of the slide has a thumb plate, by which it may be drawn outwards. The return motion of the slide is effected by a coiled spring, supported on a rod, on which rod the tail or rear end of the slide works.

—Patent completed. -Patent completed.

-Patent completed.

2854 A. M. CLARK, Chancery-lane. Electro-magnets. (A communication). Dated September 16, 1868.

A soft iron plate is united by ties to a copper plate, parallel with electro-magnets formed of coils, on a soft iron cylindrical core, resting on a plate, and supported in position by pins, their other ends being mounted on the copper plate. The apparatus is arranged so that four of the electro-magnets have their south poles in the iron plate, and their north poles in the copper plate, the other three magnets being placed in the reverse position.—Patent abandoned.

Patent abandoned.

2855 G. B. SHARPR, Llanelwedd, Builth. Fire grates.
Dated September 16, 1868.

The grate or the holder is made of bars of fron, bent into a semicircular or other form, and the ends of these bars are riveted on to two upright pieces of iron. The bottom of the grate consists of bars riveted on to the lowest semicircular side bar. The ends of the top and bottom semicircular bar project beyond the upright pieces, and are bent down, so as to form hooks, which fit into iron eyes, secured by and fixed in or upon the fixed back of the grate.—Patent completed.

2856 J.B. SPENCE and R. R. Kelly, Manchester. Pig-ments. Dated September 16, 1868.

This consists in utilizing the refuse iron arising from the purification of gas as a pigment, the sulphur being driven off by heat. A similar pigment may be obtained from the pyrites used in the manufacture of sulphuric acid.—Patent abandoned.

acid.—Patent abandoned.

2857 W. Betts, Wharf-road. Capsuling bottles. Dated September 16, 1868.

Four or any other number of revolving segments of a circle are employed, which are called "shapers," such shapers being formed to suit the particular make of bottle to be capsuled, and being of a length sufficient to cover the whole of that portion of the capsule which extends behind or below the external shoulder or lip of the bottle neck, or they may be made shorter and the bottle neck moved to and fro longitudinally, so as to cause the shapers to pass over the whole of the smooth surface of the capsule. These shapers, which are preferably made of steel or gun metal, are jointed on to the ends of hinged lever arms, or are carried by converging slides, and are caused to revolve round and converge upon and grip with any desired pressure the capsule upon the bottle neck, by the action either of springs or of the hand of the operator. The neck of the bottle, with the capsule adjusted loosely upon it is introduced between the revolving shapers, and is brought up to a central adjustable stop or gauge. The shapers are caused to revolve rapidly,

and are simultaneously allowed to close upon the capule, either by the action of springs or by the pressure upon a lever, which causes a sliding cone or its equivalent to bring the shaper levers together.—Patent completed.

2858 R. DEA. Birmingham. Combination pulvering plough. Dated September 16, 1868.

The plough-bare and its attendant parts are constructed of a treugh shape, level in the front for entering the soil, and rising behind, for the purpose of elevating the soil by the common draught action of the plough; and at the elevated rear end of the trough, in connection with the ploughshare, either above or below it, the means for separating, dividing up, and scattering the soil so elevated is applied.—Patent abandoned.

2859 W. R. Lake, Southampton-buildings, Hads for dolls. (A communication). Dated September 16, 1863. The head is moulded in two separate parts by two pairs of dies, and the parts are afterwards lapped together, the lapped surfaces being slightly moistened and united by pressure.—Patent completed.

pressure.—Patent completed.

2860 S. Beards, Stowe Park, Buckingham, Stem ploughs. Dated September 17, 1868.
This relates to a patent, dated October 6, 1862, No. 2689. The improved plough is constructed with self-acting, lifting, or tipping mechanism, and running and stop chains, and the latter are attached to the hauling rope, so that the share beams are instantaneously raised and lowered by the first "pull" of the hauling rope at each change of direction. The plough frame is fitted with a stop chain at each end, and the hauling rope connected with both of these stop chains, the free ends of the latter being provided with double hooks, for connecting them with the free ends of the running chains, and also to the share frames, to which their opposite ends are secured. In the centre of the plough frame a transverse shaft is fired, upon which a pair of grooved wheels are mounted, round and over which the two running chains are passed through one of the links of each of these chains, and also through its wheel. A crosspin is mounted to prevent the slip of the chains in the grooves. The length of the two portions of the running chains, between the crosspin and the share frames, is such, that when one set of ploughs is raised, the other is lowered.—Patent completed.

2861 J. Davey, Crofthole. Ploughs. Dated Septembers

frames, is such, that when one set of ploughs is raised, the other is lowered.—Patent completed.

2861 J. DAVEY, Crofthole. Ploughs. Dated September 17, 1868.

The shank or neck of the coulter passes down through the beam, and is supported by a pin through the coulter boss, and is imperfectly adjusted for turning or feathering from right to left, by means of two set screws. The coulter lever or tiller is hung on a stud or upright, in frost of the coulter. A slot is provided, to allow the coulter to become more or less vertical, so that the blade point corresponds with the point of the share. The shank of the coulter bearing against the set screw raises or depresses the coulter blade. The back end of the coulter lever is brought into collision with the breasts, and by the semirevolution of the latter is carried from right to left or for rests, the required position of the coulter blade to the point of the share is given. The handle of the lever is simplicated, by being placed under a hook, which is studed to or formed on each of the stills.—Patent completed.

2862 W. T. WATTS, Birmingham. Annealing raised hollow ressels. Dated Septemer 17, 1868.

Hoops or annular dies are employed, forming a case or jacket, into which the article is closely fitted. This same result is obtained by means of staves or wedge-formed pieces surrounding the article, hooped or otherwise secured, or closely-fitting dies, with a packing of said or other suitable dry material, or even moist plaster of Paris, or other plastic material, which has been allowed to set and become perfectly dry, can be employed. These packing materials are prevented from lifting, from the expansion of the article, by a suitable cover or lid closing the opening of the disc.—Patent completed.

2863 W. E. Newrow, Chancery-lane. Raising seler.

son of the article, by a suitable cover of inclosing use opening of the disc.—Patent completed.

2863 W. E. Newton, Chancery-lane. Raising state. Dated September 17, 1868.

This consists, first, in a combination of two or more cylinders, fitted with reciprocating pistons, mounted on the same rod. The cylinders are furnished with valves, operated automatically by the movement of the pistons, and thereby control the steam passages leading to the opposite ends of the cylinders, so that while either one cylinder of the pair is receiving steam on the one side or face of its piston, and discharging fluid on the opposite side or face thereof, the other cylinder has a balance of pressure established for it on both sides of its piston, and the exhaust steam in or from the latter cylinder is made by its condensation to raise water or fluid. The cylinders are thus used alternately, and are provided with ultable water ways, in connection with passages or chambers, controlled by inlet and outlet valves. Second, in a combination of condensers, placed in communication with the working cylinders at their one ends, and interpesd between the cylinders and the fluid supply pipe or pipes, and outlets or discharge pipes, in connection with suitable fluid receiving and delivery valves.—Patent completed.

2864 A. F. CAMPBELL, Great Plumstead. Ships. Dated

2864 A. F. CAMPIELL, Great Plumstead. Ships. Dated September 17, 1868. This consists in the severance of vessels for cargo pur-This consists in the severance of vessels for cargo purposes in two distinct vessels, one constructed and litted with steam or other motive power engines with rudders, and built so that the available space obsides that necessary for the crew, passengers, and light packages is devoted mainly to the stowage of the fuel, and the other vessel constructed so that nearly its whole space can be devoted to purposes of cargo or passengers. This second vessel is adapted by internal arrangements for the particular trade in which it is to be employed, and being unsinkable when hermetically closed on deck.—Patent completed.

2865 W. R. LAKE, Southampton-huildings, W.C. Explosive compounds. (A communication.) Dated September 17, 1865.

Powder No. 1 is composed of 9lb, of chlorate of potash.

Powder No. 1 is composed of 9lb, of chlorate of polash. Alb. of sulphur, and 4lb. of hight charcoal. Powder No. 2 is prepared with 2lb. of chlorate of polash. Ilb. of ine, dry white sugar, and Ilb. of ferro-prussiate of polash. Powder No. 3 is composed of 4lb. of chlorate of polash. Powder No. 3 is composed of 4lb. of chlorate of polash. 4lb. of charcoal, 1lb. of sulphur or sugar, 2nd Ilb. of ferro-prussiate of polash. 4lb. of sugar, 4lb. of chlorate of polash. 4lb. of sugar, 4lb. of charcoal, mere or less, and 4lb. of sulphur. Powder No. 6 is prepared by using one part of chlorate of polash, 4lb. of sulphur, 4lb. of chlorate of polash, 4lb. of sulphur, 4lb. of chlorate of polash, 4lb. of sulphur, 4lb. of chlorate of polash, and one part of chlorate of polash with the liquid. No. 8 consists of chlorate of polash with the liquid. No. 8 consists of chlorate of polash

pulverized and saturated with the liquid.-Patent com

pleted.

2866 H. WILSON, Stockton-on-Tees. Hydraulic fluid or teem power. Dated September 17, 1868.

This consists of a cylinder of east iron, or other suitable material on the side of which, and along the entire length thereof, a pipe or channel is fixed. On the one end of the cylinder a cock or slide valve is fixed, for admitting the water or other fluid to the interior of the cylinder a piston formed of an india-rubber ball, which rolls from end to formed of an india-rubber ball, which rolls from end to find its admitted at one end of the cylinder, is; placed. When the water or other fluid is admitted at one end of the cylinder, which is done by the action of the cock or slide valve, the ball rolls to the other and closes the Gutlet, so stopping the further supply of water until the valve or cock is shifted, so as to the other end, an in turn stops the outlet at that end.—Patent completed.

2867 G. H. Barth, Westbourne-grove. Administring

Patent completed.

2867 G. H. BARTH. Westbourne-grove. Administering gas for medicinal purposes. Dated September 17, 1863.
This relates to letters patent, dated March 17, 1854 (No. 641). The gasholder is made of zinc, or other metal, and is of the ordinary construction. It is inverted over water in a suitable vessel, which may be fitted with an interior core, if desired, in the customary way, and is fitted with a rod, sealed, to measure the quantity of gas used. It is also provided with counterpoise weights to regulate its weight.—Patent completed.

2862 T INES J JONES J BRANDWOOD, and F. WREN.

weight.—Patent completed.

2868 T. Jones, J. Jones, J. Brandwood, and F. Wren, Manchester. Furnaces. Dated September 17, 1868.

This relates to all furnaces wherein firebars are used, and wherein smoke is evolved. The improvements consist in the adaptation and use of hollow firebars, terminating at the further extremity or back of the furnace, in a chamber which is perforated, and extends upwards nearly to the top of the flue, between which and the top of such chamber the smoke from the fire passes. The air enters the spectrum provided beneath, and at the front end of the firebar, and passing along the bar, becomes heated, and thence passes into the chamber, and out at the perforations thereof into the flue, where it becomes mixed with the smoke, and assists in the burning or consumption thereof.—Patent completed.

2869 J. H. JOHNSON, Lincoln's Inn. Combustion of liquid

thereof.—Patent completed.

2869 J. H. Johnson, Lincoln's Inn. Combustion of liquid fuel. (A communication). Dated September 17, 1868.

This consists in burning liquid fuel directly, and without any admixture of steam or water, upon a peculiar grate, and substantially disposed, the liquid fuel is impelled or caused to flow over the surface of the grate by pressure. It flows in a number of small streams along the face of the several gratebars, which are grooved or channelled longitudinally for that purpose, and having connected to them at their upper ends small liquid fuel supply pipes.

These several supply pipes are fed from a regulator above, which receives the liquid through pipes, and a stopcock in connection with a tank or reservoir situate at a higher level. The air for supporting combustion enters between the grate-bars, as in the ordinary furnace grates. The furnace chamber may either be composed of fireday or surrounded with water spaces and firebrick deflecting arches or bridges may be disposed thereon, as found requisite.—Patent completed.

pleted.

2870 J. H. JOHNSON, Lincoln's Inn. Mode of advertising:
(A communication.) Dated September 17, 1868.

(A communication.) Dated September 17, 1868.

This relates, first, to a mode of advertising, and second, to a peculiar manufacture of envelopes for containing miscellaneous advertisements, and consists in printing miscellaneous advertisements, and consists in printing simple or illustrated advertisements upon envelopes, simple or illustrated advertisements of on envelopes, paper bags, bands, wrappers, and covers for newspapers, or book post and letter or note paper—Patent completed.

2871 R. SMITH, Islington. Prevention of the fouling of ship' bottoms: Dated September 17, 1868.

The patentee places a pipe or pipes along one or both sides of the ship, beginning at the keel. This pipe or these pipes is or are fitted with a compound, generating or producing a strong gas, capable of destroying all barracies, or other animal or vegetable life, capable of fouling ships' bottoms. The gas is to be allowed to escape through an opening or openings in the above-mentioned pipe or pipes, and mingle with the air and water surrounding the ship.—Patent completed.

pipes, and mingle with the air and water surrounding the ship.—Patent completed.

2872 W. CLISSOLD, Stroud. Feeding wool to carding engines. Dated September 17, 1868.

This relates to a patent, dated April 7, 1866 (No. 1000). The following modifications are introduced into the original machine:—The bars forming the bottom of the original machine:—The bars forming the bottom of the box are placed horizontally, and an alternating endway and parallel vertical motion are given them. They are armed at their forward ends with saw teeth, in order that they may the better take hold of the advancing fibres. Near the mouth of the box a rotary comb is mounted, consisting of an oval drum, carrying two rows of teeth, fixed in lines coincident with its largest radius. Behind this rotary comb a grid is set transversely to the box, and with its spaces in the planes of motion of the comb teeth. These teeth as they rotate will take hold of the fibres at the back of the grid and draw them down past a rotary gill, which is set below the grid and a little above the traversing bars, and assists in carrying the fibres forward. While it provents an undue quantity passing from the rear of the box. The fibres carried forward by the rotary comb are taken up by the saw teeth of the reciprocating bars, and delivered to the reciprocating combs before-mentioned. Immediately in rear of the upper comb plate is mounted a transverse sliding toothed blade, which receives a short endway medion, and serves to disturb the advanced fibre, and enable: the comb plates more effectually to take hold of the same.—Patent completed.

take hold of the same.—Patent completed.

2873 J. Head, Ipswich. Wire fence. (A communication). Dated September 17, 1863.

This consists of a single cylinder or windlass barrel, having a small slot in it, through which the wire is passed, thaving a small slot in it, through which the wire is passed and turn in a rectangular frame, one ent of the cylinder and turn in a rectangular frame, one ent of the cylinder and turn in a rectangular frame, which is the other end carries to the frame, as well as through holes at intervals near its cira disc fixed to it, having holes at intervals near its cira disc fixed to it, having holes at intervals near its cira disc fixed to it, having holes at intervals near its cira disc fixed to it, having holes at intervals near its cira disc fixed to be with the slot in the cylinder. When the handle is turned, the wire winds on the cylinder, and sufficient tension having been thus obtained, a pln is passed through one of the

holes in the disc into a corresponding hole in the frame, so as to lock the cylinder.—Patent completed.

noies in the disc into a corresponding note in the frame, so as to lock the cylinder.—Patent completed.

2874 C. H. Hudden, New York. Washing apparatus. Dated September 18, 1868.

This consists, first, of a wash tub or wash box, the bottom ends and sides of which are preferably joined by hitges, so that the parts may be folded compactly together when not in use, and the joints being formed and made tight by causing the V-shaped edge of one piece to set into or against a packing of rushes, flag, india-rubber, or other suitable material, laid into and slightly projecting from a dovetailed slot at the bottom or inner angle of a corresponding V-shaped groove in the opposite piece. Second, of a rubber, consisting of a rigid frame or box, in the lower ends of which the said rubber is hung or pivoted, a rock shaft or rock bar, having holes in it, through which the said swing posts pass, and the necessary horizontal rods or bars.—Patent completed.

2875 E. T. Hushes, Chancery-lane. Wringing machines.

through which the said swing posts pass, and the necessary horizontal rods or bars.—Patent completed.

2875 E. T. Hughes. Chancery-lane. Wringing machines.

(A communication). Dated September 18, 1868.

This consists, first, of one or more endless bands or belts of india-rubber hung on rollers in such a manner as to permit the articles from which it is desired to remove the water to be passed under pressure either between two such belts or between an outside roller and a belt. Second, in the combination with one or two belts of four rollers so sarranged that the articles to be wrung, in passing between the two belts, or between the single belt and two rollers, are twice wrung or subjected to pressure. Third, in the articles write the subject of the subject of two rollers of cogwheels on one or both ends of each of two rollers, the teeth of which wheels mesh into each other. Fourth, in so arranging the belt or belts and the rollers that the operation of pressing or wringing can be performed by a third or a third and a fourth movable roller of perating or pressing upon the geared rollers. Fifth, in the combination with the endless belt or band of a tightening roller. Sixth, in the combination with the jaws orl prongs between which the tub is received of a wedge thrust between a portion of the wringer frame and the tub. Seventh, in a spring made by inserting radial rolls or strips of wood or steel into a centre piece of metal. Eighth, in making the outer rolls or strips bear when the spring is compressed of a curved form. Ninth, in forming the lower of the bands with flanges or raised portions, between which the belt with a suitable yielding material, such as felt.—Patent completed.

2876 W. Cross, Paddington. Carriage doorsteps. Dated

belt with a suitable yielding material, such as felt.—Patent completed.

2876 W. Cross, Paddington. Carriage doorsteps. Dated September 18, 1863.

The patentee forms an external hinge of brass or other suitable metal, which is made with conical cavities near suitable metal, which is made with conical cavities near its extreme ends. Into these cavities pieces of vulcanized india-rubber, or other elastic material, are fitted, so that when the door is fully opened corresponding pieces of rubber or elastic material meet and act as a buffer or spring to prevent the door striking against the body. The same object is attained by fitting the door with hinges of the ordinary kind and adding the improved spring stop by placing the pieces of india-rubber in the centres of metal shields fitted with conical recesses to receive and hold them in position.—Patent completed.

2877 H. VANSITART, Richmond. Screw propellers. This consists in detailed improvements upon Lowe and Harris's patent, dated October 10, 1862, No. 2735.—Patent completed.

completed.

2878 W. CLARK, Baker-street, W. Spring boots for borses. Dated September 18, 1868.

Morses. Dated September 18, 1868.

The boot consists of a linen, woollen, silk, or leather covering, porous or waterproof, which is laced, buckled, covering, porous or waterproof, which is laced, buckled, covering, porous or waterproof, which a padding is applied.—

2879 F. TEMPLINGER Posna Prussia. Polato planting.

Patent abandoned.

2879 E. Tempelhorf, Posna, Prussia. Potato planting machine. Dated September 18, 1868.

This consists of a new contrivance for planting, by which three rows of potatoes are planted simultaneously, which three rows of potatoes are planted simultaneously. The machine rests chiefly on the hind part of a carriage, and is connected by shears by means of a clutch, with a lore part to direct the course of the machine. Three parallel rows of elevating apparatus are united perpendicularly at their longitudinal axes and convey the single potatoes from the principal receptacle into the actual planting apparatus or planting pipe close to the soil, whence they can drop singly at any desired intervals. The potatoes thus planted are then covered by a plough attached to the hind part of the apparatus.—Patent completed.

attached to the hind part of the apparatus.—Patent completed.

2880 E. T. Hughes, Chancery-lane. Grinding, smoothing, and polishing glass, &c. (A communication). Dated September 18, 1868.

This consists of a truck constructed of wood or other suitable material, mounted on wheels, and carrying a circular or other shaped horizontal table free to revolve on a cular or other shaped horizontal table free to revolve on a shaft passing through the centre of the truck, and resting on a footstep at the base thereof.—Patent abandoned.

2881 W. NEEHAM and J. KITE, Vaukhall. Depurating fluids. Dated September 18, 1868.

The object is the employment of paper as a filtering medium under high pressure. An even surface is obtained by the use of perforated plates or diaphragms of equal or of greater length and breadth or diameter than the frames forming the supply and discharge chambers. A textile fabric—an ordinary filtering cloth, for example—is interposed between the paper and the perforated diaphragm. To enable the ensy introduction of paper into the press, holes are made in the frames, forming supply chambers in the perforated diaphragms, and in the cloths. These holes correspond with short tubes set in holes in the frames forming the discharge chambers, so that when the whole are placed in juxtaposition they form supply and discharge conduits traversing the press or depurating apparatus from end to end.—Patent completed.

2882 J. SMITH and J. DEWNNEY, Leadenhall-street.

apparatus from end to cud.—Patent completed.

2832 J. SMITH and J. DEWDNEY, Leadenhall-street.

Steam boilers. Dated September 18, 1868.

The inner tubes are extended some distance above the upper ends of the outer tubes, and are connected together by means of a solid plate or diaphragm, in which such inner tubes are firmly secured, either flush with the plate or projecting above the same if required. In the plate other apertures may be formed in which other tubes may

be fixed, passing up to, above, or below the water level, for facilitating the conveyance of the steam to the steam spaces of the boller. The plate also serves to prevent priming, and to receive some of the solid matter contained in the water. The plate may be flat or convex, and may be formed in segments, or with ribs or corrugations. In another arrangement, the outer tubes are carried up above the crown plate to the before-mentioned plate or diaphragm in which they are fixed, either flush or so as to project above the same, and the upper ends of the inner tubes are formed with a bend passing through the outer tubes at a point between the crown plate and upper plate.

—Patent completed.

2883 W. H. Hughan. Newton Stewart. Treating accounts.

Patent completed.

2883 W. H. Hughan, Newton Stewart. Treating seesage.
Dated September 18, 1868.
This consists in the application of Portland, Roman, or other suitable cement, to deodorize and solidify night soil, sewage, filth, urinary and bestial products of farm steadsewage, filth, urinary and bestial products of farm steadings, shudge, the waste of manufactories, and refuse in general.—Patent completed.

general.—Patent completed.

2834 G. Bernhardt, Radeliffe. Preparing spinning
and doubling fibrous materials. Dated September 19, 1868.
This consists, first, in applying a shaft or bar to machines for preparing spinning or doubling fibrous
materials where leather covered rollers have to be pressed
upon fluted rollers by weights, levers, or springs, so that
upon fluted rollers by weights, levers, or springs, so that
upon the rollers may be simultaneously removed or applied
at will. Second, in securing the cloth at intervals to the
plate or cover to allow it to traverse with
in slotting this plate or cover to allow it to traverse with
the "drag cloth." Third, in the use of an L trough to
receive the full bobl ins. the front of the copping rail
forming one side of the trough.—Patent completed.

2835 IT. Berney, Bracon Hall. Norfolk. Construction of

2895 T. BERNEY, Bracon Hall. Norfolk. Construction of defensive armour. Dated September 19, 1868.
This relates to a prior invention patented January 26, 1867. No. 193, and consists in a number of Improvements in the details of the construction of the defensive armour, &c., therein described.—Patent abandoned.

286 M. MACDERMOTT, Edwarde-square, W. Street lemp reflector. Dated September 19, 1868.

A disc is placed within the lamp above the flame, and beneath it are four vertical plates crossing each other at right angles with the opposite angles of the lamp frame.

—Patent abandoned.

Patent abandoned.

2887 J. BLAKEY, Leeds. Repairing boots. Dated September 19, 1868.

This consists in making a last of iron or other suitable metal instead of wood. The last is made in two halves, connected at the heel by a hinge joint. Each part is internally recessed, and tapers towards the toe to a lmit the passage of a screw boit, to the outer end of which a the passage of a screw boit and the heel part of the last. through which the screw acts as a fulcrum, and when the screw is urged forward, the toe, by reason of the guide working within the tapered part, is opened out as much as requisite.—Patent completed.

2888 F. Dyer. Camden Town. Hot scales apparatus

much as requisite.—Patent completed.

2888 F. Dyer, Camden Town. Hot water apparatus.
Dated September 19, 1868.

This consists, first, in the use of the tubular fireback made of malleable iron or other metal cast in one piece from tubes crossed or cast or wrought in any other way, or constructed of pipes or tubes of any form or shape and of any metal. Second, in the manner of connecting the tubular fireback with the hot water cylinder. Third, in the application and use of a return pipe with ball valve inserted to prevent the upward flow of water in the return pipe. Fourth, in the method or mode of connection by which all parts of a dwelling house or other building can be supplied with hot water by the use of a hot water cylinder, reservoir, or tank placed near the kitchen lire and in connection with the tubular fireback.—Patent completed.

pleted.

2889 W. HAYNES, Middle Hutton. Drewing leather
Dated September 19, 1868.
This consists in an improved machine for performing
the operations in dressing leather known as washing
the operations in dressing leather known as washing
the operations in dressing leather known as washing
the order of the various properties.
Also in drawing the goods out of the vat or pit in which
they have been worked by an improved method. The
machine can be applied to washing cotton waste, rags, and
other materials.—Patent completed.

other materials.—Patent completed.

2890 J. Brown, Huddersfield. Extracting water and other liquids from raw material and manufactured goods.

Dated September 19, 1868.

The apparatus consists of a concave table, dish, or essel (by preference, fluted), upon which the substances to be operated upon are to be placed, to which a pipe in connection with a pump is applied. A cap or cover of india-rubber or other air or waterproof cloth or flexible material is attached to the edge of the dish over the substances.—Patent abundoned.

2891 L. DESENS, Charling Cross. Miner' lamps. Dated

stances.—Patent abandoned.

2891 L. DESENS, Charing Cross. Miners' lamps. Dated
September 19, 1868.

In the centre of the gallery and platform bearing the
wick-holder is a cylindrical tube (an opening being cut
for its reception), round which a spring is coiled; in the
interior of the cylinder is the wick-holder, which is a
small tube having soldered or otherwise fixed at one side
three small teeth, which goar with an endless screw tarning on an axis. The shaft on which this is mounted
revolves below in a small tube.—Patent abandoned.

2892 G. INNER New Cross. Eding spathings. Dated.

revolves below in a small tube.—Patent abandoned.

2892 G. INNES, New Cross. Rifting machines. Dated
September 19, 1868.

The bed of the machine is constructed like that of an The bed of the machine is constructed like that of an ending the leads. Upon this bed a saddle or carriage removing the heads. Upon this bed a saddle or carriage removing the neads. Upon this bed a saddle or carriage is fitted, and connected by a suitable nut to a screw extending from end to end of the bed. Parallel with this screw, and preferably outside the bed, is a toothed rack, into which is geared a pinion, fixed on a short transverse screw spindle, supported in suitable bearings on the screw spindle, supported in suitable bearings on the travelling carriage or saddle. The latter carries a rack, which is litted to work in a guideway. This rack is converted by a nut, with the transverse screw, and gears into a pinion on the thrust bar, to which the tool bar is fixed, which bar is thereby caused to rotate as the carriage or saddle moves along the bed. The pitch of the rifling is varied by changing the relative speed of the carriage and thrust bar.—Patent abandoned.

2893 B. Dickinson, Hopetown, India. Treating leaves of

2893 B. DICKINSON, Hopetown, India. Treating leaves of tea plant. Dated September 19, 1868.
For the purpose of removing the julces, the fresh gathered leaves, or the gathered leaves, which yet contain

in their cells the natural juices, are pressed in a bag made of hair, or other strong and porous material. For the purpose of rupturing the vessels of the leaves, without otherwise breaking or injuring them, the bag containing the leaves is placed between a pair of rollers, under pressure, obtained by well-known mechanical means, and one or both of the rollers are caused to rotate, so that when the bag has been passed through the rollers once or twice, the whole, or a sufficient amount of the juices, shall be expressed from the leaves. For rolling (cigar like) the leaves, an endless band, upon which the leaves are received and carried forward against and under freely revolving rollers, but which may be capable of being regulated or retarded in their motion: or instead thereof is employed two endless bands, moving in contrary directions, but parallel to each other, horizontally, may be made use of.—Patent completed.

2894 B. Dickinson, Hopetown, India. Withering and

directions, but parallel to each other, horizontally, may be made use of.—Patent cempleted.

2894 B. Dickinson, Hopetown, India. Withering and desiccating leaves. Dated September 19, 1868.

The object is the more uniform, perfect, and economical treatment of the leaves of the tea plant, and the leaves and flowers of other plants, requiring to be prepared by withering and desiccation. A current of heated air, admitted under regulation as to its temperature, volume, and velocity, is employed, directed so as to come in contact with, and pass through, amongst, and over the materials be treated. A series of trays or shallow boxes, without covers, are constructed of the same size, and capable of fitting into and side by side the one with the other, each having a bottom of open cane work, upon which the green leaves or other materials are heaped, to a suitable thickness, to allow of the air pressing freely up through and amongst the leaves. These trays are placed in or upon a frame of woodwork, upon an open top trough of brick or earth, with closed ends, of such dimensions as to take one or two of the trays, two or more in height, and several in the length of the frame, and one set of trays is so set against the other, and one layer of trays so set upon another, that the heated air passing into the trough can only escape through the bottoms of the trays containing the leaves, and so through the leaves, withering and desiccating them in its passage.—Patent completed.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining cepies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our recaders are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shilings may be remitted in postage stamps, for sums above that amount a Post Office MoneyOrder should be sent, payable to ROBERSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, Loudon, E.C., to whom all communications upon the subject should be addressed.

LONDON: FRIDAY, APRIL 9, 1869.

# EXPERIMENTS RECENT GUNNERY EXPER AT SHOEBURYNESS.

THE recognition by the United Government of the superiority of rifled oversmooth-bore artillery, as lately announced in our columns, hardly prepared us for further experiments with this class of ordnance in our own country. Nevertheless, on Wednesday week, Shoeburyness re-echoed to the reports of the 15-inch Rodman gun, which has been fired, not, however, so much with a view of experimenting with the gun as testing some new cast shot recently made in England. The gun was laid against the Plymouth case-mate at 200 yards range. The powder charge was 83¼lb. of large grain powder, and the three shots fired weighed 457lb., 451lb., and 450lb. respectively. The new shot are spherical, and are made from a mixture of cast and refined iron at the Woolwich Laboratory, upon the method patented by Dr. D. S. Price, the original material having been first proposed by him to the Iron Plate Committee of 1862, both for projectiles and guns. The three rounds fired were highly interesting, as proving that round shot for large smooth-bore guns can be made in England of superior quality to the American shot. They, moreover, possess this advantage, that whilst the American shot are all turned true by ma-chinery, these shots are cast in moulds with such exactitude as to be ready for use without any such subsequent mechanical operation. The three Price's shots fired on the present occasion were true to the 1-300th of an inch, and passed through the gauging rings both ways with exactitude.

The first round with the 457lb. shot struck the 20-inch thick portion of the Plymouth casemate, making an indent 15 in. across, and 5in. deep, the indent, being saucer-shaped, with very steep rounded sides; 9in. below the indent was a curved crack, 2ft. 4in. in length; and, above it, a crack extended diagonally 9in to an empty bolt-hole, and thence beyond to the upper proper left corner of the lower portion of the plate. From the above bolt-hole, another crack ran off at right angles to the first. A large triangular piece of the covering plate, measuring 3ft. 8in. by of the covering plate, measuring 511. Sin. by 11in. by 16in., was carried away. The head of a 3-inch through bolt was also broken off, whilst behind the plate the 5-inch face plate of the proper 15-inch thick structure of the casemate was indented and buckled. At the rear of the casemate, the vertical buttress on the left proper of the port was bent; another vertical buttress 2ft. to the left was also bent. The second round was with the 451lb. shot, which struck the 15in. portion near the porthole. More than half the shot remained fixed in the plate, plugging the indent, the centre of which was 3ft. 11in. from the granite base, the upper circumference of the shot being only 2in. away from the upper edge of the plate. The metal here was split through, but there was no other fissure in the plate in direct connection with the shot-hole. Cracks extended in various directions, and at the rear The 450lb. considerable damage was done. shot, in the third round, took effect on the upper portion of the proper left wing of the casemate, where it was 20in. thick. It brought down two large pieces of the plate, which had been battered in previous experiments. The centre of the indent was 16in. from the proper centre of the indent was folia. From the proper right edge of the covering plate, adjoining and in line with the upper part of the port, the shot-hole being plugged by more than half seconds. In Mr. Pettman's fuze, the detonation of the detonation of the port, seconds.

At the rear, the shot, which remained in it. the vertical buttress on the left of the porthole was bulged and otherwise slightly damaged.

The striking velocities of the shot were as follows:—Round one, 1,360ft. per second; round two, 1,370ft.; and round three, 1,383ft. The general effects upon the Plymouth casemate structure were very remarkable, in the flaking away of the thick face and covering plates, and in the bursting out of large portions of the rear planks and vertical struts.

The first action of impact upon the front plates was to block out squarish areas by the extension of the old fissures of former rifleshot wounds; then the effect of the vibration of the layers of iron plates and planks against each other was to cast these blocked-out spaces to the front, a peeling action tending to the rapid disintegration of the iron wall. The results were highly satisfactory in establishing the valuable character of the metal of which the shot were composed. Next week which the shot were composed. Next week we shall give an engraving and description of the Rodman gun, in accordance with wishes expressed by some of our readers, since our article on "American Ordnance," which appeared a fortnight since.

The remaining experiments on the same day were made in order to test the endurance Colonel Shaw's muzzle-pivoting gun carriage on a wrought-iron platform. In these, the 10-inch 18-ton rifled gun was employed, and from it thirteen rounds were fired. The weight of the carriage was 155½cwt., and that of the platform 73¾cwt. There were eleven gallons of water in the hydraulic buffer, and the charges consisted of 60lb. of large grain rifle powder and 400-pounder projectiles. The results may be thus summa-rized:—Rounds one to five were point blank, rized:—Rounds one to five were point blank, the recoils being respectively 4ft. 6in., 4ft. 7in., 4ft. 9in., 4ft. 9in., and 4ft. 7in. Rounds six and seven were fired at 1deg. elevation, and the recoils were 4ft. 7in. and 4ft. 5in. Round eight, at 4deg., showed a recoil of 4ft. Round nine, elevation given 9deg., recoil 4ft. 3in. The gun ran down 1deg. after firing this round, through the slip of the clamp. Rounds ten through the slip of the clamp. Rounds ten and eleven, at 9deg., gave recoils 4ft. 2in. and 4ft. 2in. Rounds twelve and thirteen, at 10deg., gave recoils of 4ft.1in. and 4ft. 2in. Throughout the trials, the carriage worked well, nothing whatever going wrong in its

action.

Another series of experiments was carried out this day week with the first of a new class of heavy ordnance-a 4-ton 9-inch howitzerand with sensitive fuzes required for projecand with sensitive fuzes required for projectiles of this kind of artillery when low gun charges are employed for vertical fire. The gun is made of wrought iron on the muzzle-loading principle. It is rifled with five grooves, the rifling having a uniform twist of one turn in thirty-five calibres. The gun weighs 76cwt. 2qr., and has a breech preponderence of 2cwt. 3qr. 2lb.; the length over all is 6ft. 4in., and length of bore, 4ft. 6in. This howitzer was mounted on a wrought-This howitzer was mounted on a wrought-iron bed placed on a 13-inch sea service mortar octagonal wood deck, the weight of the iron bed being about 42cwt. The arrangement for traversing was by two eccentric gun-metal trucks, one at the front and one at the rear of the bed, working upon two flat circular gun-metal racers screwed down on the wood deck, the bed being kept in place by a strong central iron 13-inch mortar pivot. The elevation of the howitzer is obtained by arc-racks and pinions on each side of the iron bed, the piece being clamped in its posi-The maximum elevation tion of elevation. obtainable is about 40deg. The fuzes were of three kinds, viz., a metal percussion fuze, designed by Mr. Pettman, and made more sensitive than the service metal percussion sensitive than the service metal percussion fuze which bears his name; a metal percussion fuze, proposed by Colonel Boxer; and a service Boxer wood time-fuze for muzzle-

ing ball is heavier than in his service fuze, the fulminate is more sensitive, and the surface of the chamber is corrugated to facilitate the detonation. Colonel Boxer's fuze is a cylinder containing the meal powder charge at the rear end, this being covered with a brass cap resting on ledges in the cylinder and containing the fulminate in its centre. Over this again is screwed a sunk thin brass disc, with an anvil projecting inwards over the fulminate to about the tenth or fifteenth of an inch from its surface. When the fuze in position in the head of the rifle shell strikes ground, the earth is driven in upon the thin metal disc, and forces the anvil suddenly down upon the fulminate, thereby producing detonation.

The shells used in the first part of the experiments were of the ordinary character, 18in. long, and having a capacity for a bursting charge of 7lb. of powder. They were ing charge of 7lb of powder. They were weighted up to 200lb., in some cases by sand and sawdust at the bottom of the shell, the top portion only being filled in with powder to give a report or burst. It was necessary to adopt this precaution in order to prevent the possibility of accident, in the event of any of the fuzes acting prematurely when the shells were fired with a howitzer charge much less than the bursting charge of the shell. In other cases, when the fuzes were found not to act prematurely, the shells were filled up with the full charge of 7lb. The powder used was, in all cases, rifle large grain. In the first series of trials, an elevation of 35deg. was given to the howitzer. Rounds one, two, and three, were fired with a Pettman's fuze and three, were fired with a Pettman's fuze and a 3lb. powder charge, which charge was used for twelve rounds. The times of flight were respectively 14·2sec., 14·3sec., and 14·1sec. to graze; the fuzes, however, failed to act. Rounds four, five, and six, were with a 20sec. wood time fuze unbored, a similar fuze bored to 2·8in, and another fuze of the same kind unbored. The times to the first graze were 14·0sec., 14·4sec., and the first graze were 14 0sec., 14 4sec., and 14 1sec. In the fourth and sixth rounds, the fuzes did not act; in the fifth, however, the burst took place upon impact with the sand.

The seventh was an unbored fuze, with a cravat of quick-match tied round the top of the fuze to insure ignition, which, however, did not take place. Numbers eight and nine did not take place. Numbers eight and nine were bored 2 6in. and 2 8in. respectively; the first burst 30ft. above the plane of the range, and the second on impact with the sand.

Colonel Boxer's fuzes were tried in rounds ten and eleven, and both burst on impact on the sands, the grazes being at 14 Isec. and 14 Osec. Round Number twelve was with Three holes had been a Pettman's fuze. Three holes had been bored through the steadying plug, to act as air passages, to assist the recession of the steadying plug after the fuze was put in action by the firing of the howitzer charge. The fuze, however, did not act. The powder charge was now increased to 6lb. for the next two charges, which were the first with a two charges, which were—the first with a Pettman, and the second with a Boxer fuze. The graze took place at 20 4sec. with Pettman's, but the fuze did not act, whilst Boxer's burst on impact with the sand.

In the second series of experiments, the howitzer was at an elevation of 15deg., and was fired with 10lb. powder charges. Rounds one and two were with Pettman fuzes; the one and two were with 1 certain time of flight was 12.3sec. in each case, and time of flight was 12.3sec. in each case, and the impact with the sand. The both burst on impact with the sand. The third and fourth rounds were with Boxer fuzes, which also burst on impact after flights of 12 1sec. and 11 8sec. respectively. A shell was next filled with sand to 200lb. and fired, plugged with a 20sec. wood time fuze, for the purpose of ascertaining the time of flight of purpose of ascentaining the time of such a missile fired with howitzer charge of such a missile fired with howitzer charge of 25deg. The 10lb. of powder at an elevation of 25deg. The time of flight was ascertained to be 19.9 sec. After this the fuzes were further tested by firing into earthwork at 800 yards from

service charges, namely, for the 12-pounder 8oz., and for the 40-pounder 1lb. 1oz. r.l.g. powder. Shells with reduced bursting charges. The practice was made with Boxer fuzes, Mr. Pettman having withdrawn his from the trials for further modification. Of the first five rounds, two were at 7deg., one at 7deg., and two at 8deg. of elevation. The first shell burst on graze short of earthwork; the second grazed short, ricocheted over earthwork into sea, blind. The third burst on graze 20 yards short, whilst the fourth and fifth hit the work and burst. Five more rounds were then fired at the respective elevations of 9, 10, 101, 101, and 101 deg. The first shell grazed 100 yards short, blind; the second grazed 40 yards short, blind; the third grazed 30 yards short and burst; the fourth grazed to left 40 yards short, blind; and the fifth grazed 100 yards short and ricocheted into the sea, blind. This concluded the experiments, which proved the inefficiency of the Pettman fuzes. The results of the firing upon the howitzer were also unsatisfactory. Being made of Marshall's iron, the bruising of the studs of the heavy projectiles upon the soft metal, even with the low charges of 3lb., considerably injured the rifle grooving. So much is the piece injured, that it will probably have to be returned to the gun factory to be fitted with a Firth's steel tube. These fitted with a Firth's steel tube. results are not altogether so satisfactory as were anticipated, or as could be desired.

### INDO-EUROPEAN TELEGRAPH.

THE progress towards the completion of this line is of so satisfactory a character as to render almost certain its being finished and in successful working order within the time specified in the contract. sidering the numerous engineering culties in the way, this result cannot but be considered as very favourable. It may be in the recollection of our readers, that this scheme was projected last year, for the erection of a double line of telegraph between England and Teheran, in Persia, so that, in connection with the Persian Gulf cable, we might possess an uninterrupted line of telegraphic communication between this country and our Indian possessions, with the great advantage, that, although passing through three foreign countries, this line of telegraph, by virtue of the several concessions, would, for all practical purposes, be in our own hands, and under our own system of manipulation. Such a result must contrast favourably with the present system of telegraphic transmission through the many countries messages now pass. Starting from London, the line may be considered complete as far as Nordeney, for, for that distance, two existing wires are leased from the Electric Telegraph and Reuter's Telegram Companies (the speedy transfer of these two companies to the Government in no wise interfering with these leases). From Nordeney to Thorn the two wires are being constructed by the Prussian Government, and there is every probability of this part being speedily completed. There being no engineering difficulties in the way, carriage and transport being easy, this section requires no further notice; but from Thorn, on the Prusso-Russian frontier, the difficulties to be encountered are somewhat numerous, and deserve some mention.

The great difficulty throughout has been the question of transport, the out-of-the-way ports, and subsequent scarcity of carriage to the required points. In some sections, iron posts are used, whilst in others, the native

having to be floated down the rivers on the breaking up of the ice.

The next section is from Balta via Odessa to Kertch (through the Crimea), to Ecater-neador, and thence to a point on the Black Sea (near Djuta), the northernmost end of the Black Sea cable. This section is about 750 miles in length, and includes two heavy cables, one crossing the Straits of Kertch, a length of 15 miles, and the other, a length of about 4 miles, across the Dnieper; the construction of this part will be of iron posts, those known as Seimens', all of which, with the necessary materials, have been forwarded, but owing to the severity of the winter, they had not, according to our latent accounts, been distributed. The cable from near Djulfa to Suchum Kale will be a three-wire cable of about 100 miles in length; the conductors are of the usual size stranded wire, 107lb. to the nautical mile, covered with alternate layers of Chatterton's compound and gutta-percha, to the weight of 166lb., making a total weight of 273lb. per knot. These three conductors are laid up together and covered with hemp, having for external protection four strips of thin copper laid round helically on Mr. Siemens' patented plan, this having for its special recommendation the freedom from injury by the "teredo," and from corrosion by sea water. The insulated conductor is being made at the Gutta-Percha Works, Wharf-road, and the cable, as well as the smaller sections, is being sheathed at the cable works of Messrs. Siemens, at Charlton. ends of the Black Sea cable are to be sheathed with heavy galvanized iron wires, protected by tarred jute; this cable it is expected will be submerged in June next. From Suchum Kalé, the land line proceeds via Tiflis to Djulfa, a length of 570 miles, and from Djulfa to Teheran, a length of 450 miles. For the line from Suchum Kalé, the iron posts and material were shipped to Poti in the Black Sea, and from that port a difficulty of transport was found. In one part, across the Surat Mountains, a way had to be cleared through original forests, by hewing down trees and brushwood, but in spite of the many difficulties, the work is progressing satisfactorily. For the section from Djulfa to Teheran, the material was forwarded via Russia down the Volga to the Caspian Sea, and so to the Persian ports at the south of the Caspian; the difficulties of transport in this case into the interior were not so much from the nature of the country as from the This scarcity, scarcity of beasts of burden. through good organization, has been neutralized, and it is expected by the end of July this section will be completed.

The contractors for the whole line are the Messrs. Siemens, the most experienced of all telegraph constructors, and, from the amount of work already previously executed by them, and from the excellent manner in which their work is usually carried out, we may fairly expect this work—so large and so extensive, encountering so many difficulties—to be as perfect a system of overland telegraph as modern engineering is capable of constructing. Of the quality of the materials, Mr. C. W. Siemens, in his report to the directors, mentions, "It is, however, very important that the line should be constructed of such materials as will ensure its permanency under the most varied circumstances of climate, and without involving the necessity of frequent repairs. For this purpose, iron posts of great strength, wire of unusual thickness and tenacity, and insulators of superior construction, have been selected under the concurrent advice of the three official directors

Government have determined to improve their lines from Teheran to India. lines proceed from Teheran via Ispahan and Shiraz to Bushire, on the Persian Gulf, from thence by submarine cable to Kurrachee. From Teheran the wooden posts now in use are to be replaced by Siemens' iron posts; and a submarine cable of about 500 miles will be laid from Bushire to Jask; and from Jask to Kurrachee the land line will be extended and completed; so that, through the Persian Gulf there will be two cables between Bushire and Jask, and from that point to Kurrachee, a cable and a line, thus giving us a double communication through the whole extent of the Gulf. The cable intended for the Persian Gulf has been, as we previously informed our readers, manufactured, and was shipped on board the ships "Calcutta" and "Tweed." The accident to the former, necessitating the postponement of the expedition, is of too late occurrence to necessitate our recalling it; but, in spite of the unavoidable delay, the cable will be laid, and the alternative communication be completed be-fore the "Indo-European" line. It is, however, satisfactory for us to be able to announce that the 70 miles payed out from the "Calcutta" after her collision has been entirely recovered, through the skill and ability of Mr. F. C. Webb, C.E., who was specially sent out to dredge and to endeavour to recover what he could of the lost cable.

As the present article is intended to deal purely with the projected means of communication to India by this route alone, we do not refer here to the other projects that have been brought forward for a similar purpose, our object being to lay before our readers some account of the special features of the overland Indo-European telegraph. On the completion of the line, it is intended to work the line by means of a new automatic instrument recently patented by Messrs. Siemens: and they are not without the hope of working through, from London to India, without manual transmission—a "consummation," we say, "most devoutly to be wished." We have watched this scheme from the commencement with lively interest, and shall continue to do so; and, as the works progress, will endeavour to keep our readers well informed; and, on its completion, we trust to be able to furnish some details as to construction and working that cannot fail to be interesting.

# MANUFACTURE OF CAPS AND CARTRIDGES. No. V.

N our last article we had arrived at the stage in which the fulminate of mercury was transported to the first of the sheds, where the minor operations of converting it into a detonating substance were commenced. In certain proportions with nitrate of potash, it is reduced, by mixing, to the consistency of a thin semi-fluid paste, and while in this condition it can be safely manipulated upon a table constructed with a false bottom. During winter, a jet of steam circulates through the space so formed in the table. After bruising the paste with a roller, it is transferred to another shed, and deposited upon frames covered with unsized grey-coloured paper, which abstracts all the superfluous humidity. So soon as it is half dried, it is passed through a sieve of large meshes, from which it falls in a series of small threads, resembling vermicelli. These, in becoming still drier, change into greyish-coloured grains which are received in a graduated glass, which is grown timber has been made use of. The section from Thorn to Balta via Warsaw, about 800 miles in length, will be constructed with heavy timber, the posts being of oak, 27ft. in length by 6½in. diameter at top; all this timber has been felled, and a large part carried to its destination, the mode of transport being by means of aledges, the remainder of the section from the timber has been insured by the adoption of the tests during their manufacture." On the completion of the above double-wire system, it is but fair to expect improved communication with place the whole route port being by means of aledges, the remainder of the section from Thorn to Balta via Warsaw, and a high quality of these closed with a very smooth description of cork, resembling what is usually termed "velve" cork." A spherical form is imparted to the grains, by means of a rotatory motion very carried to its destination, the mode of transport being by means of aledges, the remainder of velves and the section from the time of velves distinct or the time of these once in a graduated glass, which is closed with a very smooth description of cork, resembling what is usually termed "velves" cork." A spherical form is imparted to the grains, by means of a rotatory motion very carried to its destination, the mode of transport of the above double-wire system, it is but fair to expect improved communication with places. The closed with a very smooth description of cork, resembling what is usually termed "velves" cork." A spherical form is imparted to the grains, by means of a rotatory motion very carried to its during the above double-wire system, it is but fair to expect improved communication with places. table silk. These frames are carried into another shed which contains large copper cylinders heated by steam, thus constituting it a drying room. The walls of this apartment are furnished with shelves or brackets to receive the frames, and when the powder is sufficiently dried, it is transported into a fourth shed, similar in appearance to those through which it has already passed in the process of manufacture, and which is protected by the same precautions. Here it is sifted through a sieve of skin, perforated with small holes, which allow the smaller grains to fall through, but arrest those of larger size. These are collected and remixed with the pasty mass, constituting a succeeding preparation. The smaller grains are sifted through a second sieve, having still narrower meshes, and the same result ensues. Some pass the meshes, while others are retained. In this instance, however, it is not the larger grains which are arrested by the sieve that are sent back to be mixed up with the paste, but the finer which fall through. Those that remain on the sieve are of the size required. They constitute the detonating powder intended to fill the caps, and by means of a paper funnel are poured into large bottles, constructed especially for the purpose.

So far, ordinary care and precaution in the manipulation of the powder will suffice to ensure the protection and safety of the workmen employed in its manufacture, but in the succeeding operations it is impossible to use too much discretion. This is entailed in consequence of the extreme degree of dryness now bestowed upon the substance, the danger and humidity being regarded in inverse ratio to one another. The bottles, with the contents that are the results of the day's work, are every evening deposited in a sort of cupboard with iron shutters, or, as it might be correctly termed, a powder-proof press or safe. This safe is recessed in the casemate, which forms the protecting barrier between the workmen and the manufacture of the fulminate, and communicates with an exterior cylindrical passage covered with a layer of asphalte, in a manner similar to that already alluded to, as forming the coating of every medium by which the powder is conveyed from one spot to another. When it is re-quired to transfer some of the fulminating powder from the safe to the workshop, it is placed in gutta-percha bottles, which, however, are not permitted to be carried into the workshop, as the danger of explosion, and especially the consequences of such a catastrophe, increases obviously with the quantity or mass. The only person allowed to handle the powder is the foreman, who, after the gutta-percha bottle has been deposited in another, or, rather, in a kind of round box constructed of thick plate iron, with the greatest possible care, takes it up and pours out a certain quantity into another box. The dimensions of this lastmentioned box are 61in. by 31in. filled, it is placed upon an iron stand, which is separated from the rest of the workshop by a large and strong iron screen. A hole is bored about the middle of this screen, oppo-site to which is placed the small box filled with powder in the manner just described.

In each of these filling rooms there are but four persons at the most. The copper caps, with their cavities uppermost, are first of all placed by a woman in an iron holder pierced with ninety-eight holes, and opening by means of a hinge-joint. When furnished with caps, a workman takes them and pushes them through the hole in the screen under the box filled with powder. The manner in which the caps are filled is very ingenious. The box has a double bottom perforated with holes which are not opposite to one another. In the space thus formed, a plate, also perforated with holes, traverses backwards and forwards. Supposing the plate to be in its normal position, or that in which it fits in the

space, its holes correspond with those pierced in the upper bottom of the box, and it consequently receives a certain quantity of pow-der regulated by its own thickness. If the plate be now pushed forwards, those portions of its surface which are not perforated stop up the holes in the upper bottom of the box, while its own holes are now opposite or over those pierced in the lower bottom of the box. At this juncture, the holder furnished with the caps comes exactly under the holes, so that the cavity of the caps corresponds with them to a nicety, and they therefore receive the powder through them, the quantity of which forms the proper dose for each cap. The workman now draws out the holder and hands it to the foreman, who places it under a balance. A plate descends with the movea balance. A plate descends with the move-ment of the balance, carrying upon its lower surface as many small punches as there are caps in the holder. These punches are re-cessed a little at the points, and, by the descent of the balance beam, compress the powder, which takes a slightly conical shape, corresponding to the cavity in the punch.

Some of our readers will probably be surprised, particularly after what has been stated respecting the danger of explosion, that the pressure of the punch does not cause the fulminate to explode. A distinction must be here made between a pressure and a shock or blow. Frequently, the slightest shock will cause a detonating mixture to explode, but it will nevertheless stand a very strong pressure gently applied. As a proof of the correctness of our statement, we may refer to an explosion of fulminating powder which recently took place at Messrs. Kynock's cartridge and per-cussion cap manufactory, Aston, near Bir-mingham. A number of girls were engaged in one of the processess connected with the preparation of cartridges. A number of these cartridges were being dried upon a hot slab, and one of the girls was brushing them off quickly with her hand, when the friction with the slab caused an explosion. Five girls were much burned in their faces. Formerly, it was the practice to fix the powder in the caps by the application of a drop of varnish; but since it has been demonstrated that it will support without explosion a direct pressure of forty atmospheres, there is no necessity for any other method of accomplishing that result than the pressure of the punch. To obviate any chance of a shock being communicated to it in the operation of compressing it in the cap, the apparatus is covered by a strip of thick leather.

The filling of the caps intended for cartridges to be used in small arms, which are manufactured for the purpose of saloon practice, is effected, with some trifling modifications, in the same manner, to which we shall allude in our next.

# INSTITUTION OF NAVAL ARCHITECTS.

THE next paper we have to mention is one read by Mr. J. Scott Russell, "On Railway Communication across the Sea." This paper we may fairly divide into two parts, one being a joyful account of what has already been accomplished in Switzerland, and the other being full of "lamentations and mourning" over what has not been accomplished between England and France. Mr. Russell has lately been engaged in superintending the construction of what we may call a steam ferry across the Lake of Constance, from Romanshorn to Friedrichshafen, to connect the railways of Switzerland, on the one shore, with those of Wurtemberg, on the other. The ferry boat is on the model of a railway station, with two lines of rail. A drawbridge, which allows for a rise and fall of something like 10ft. of water in the lake, connects the rails on the ferry boat with those on terra firma. No mechanism is required

for lowering the train on to the ferry boat, or for raising it on the other side, but the ordinary locomotives; in fact, the locomotive has sufficient power in its brakes to embark itself with ease and safety, and sufficient power to disembark as easily. The ferry boat is roofed in with a kind of upper deck, which forms one of the chief sources of strength in the whole structure, and affords a pleasant promenade in fine weather. The boat is fitted with paddlewheels, which are, however, detached, and are worked by different engines. This enables the steering of the ferry boat to be regulated with the utmost nicety, and contributes largely to the success of the undertaking. This will easily be seen when we say that the draught of the boat is about 6ft., and that at times there is not more than 6ift. of water in the harbour, and that the harbour, moreover, is very narrow and tortuous.

From the success which has attended this undertaking, Mr. Russell argues that an equal success probably would attend a similar undertaking for crossing the Straits of Dover. There is scarcely a difficulty to be apprehended in applying this method of intercommunication between England and France, that has not been encountered and overcome on the Bodensee. The chief difference is, that while on the inland lake we meet with sudden squalls, which beat up the surface of the water into an angry sea of short sharp waves, the twenty miles between Dover and Calais are open to the long heavy swell that follows an Atlantic storm. The importance which attaches to the intercommunication between England and France is of such magnitude that any means of increasing the facility of intercourse would be met with favour. This seems a very feasible method, and we think that an attempt should be made to connect the railway systems of the two countries in this way, before several millions are thrown away on any of the extravagant schemes for throwing bridges across the Channel, or of tunnelling beneath it.

Captain Selwyn, R.N., who seems to take a pride in his profession, and an interest in all connected with it, favoured the Institution with a paper "On Liquid Fuel," a subject on which he has written before. Experiments were made about a year ago, by the Admiralty, on liquid fuel. A boiler was fitted to a steam launch, for the purpose of these experiments. This boiler, during a trial of 73 hours with coal, evaporated 7.06lb. of water per 1lb. of coal per hour, and during a trial of 33 hours with oil, it evaporated 10.32lb. of water per 1lb. of oil per hour. In these experiments the furnace is fed by an injector, formed of two pipes, of which the inner one supplies the oil, while the outer is connected with the boiler. This is the Wise, Field, and Aydon principle which has often been referred to in our pages. The steam from the boiler, besides, perhaps, performing other useful offices, throws the oil into a fine spray—a form very conducive to complete and rapid combustion. The best arrangement seems to be to supply equal weights of steam and oil. There is another way of burning the oil, made use of by Messrs. Dorsett and Blyth, with which our readers are also familiar. The oil is heated in a retort till it takes a gaseous form, and it is then burnt, like ordinary gas, issuing from a series of small apertures in a coil of iron pipe. No steam is required in this method, but Captain Selwyn prefers the other, on account of its simplicity, there being little or no difference in the calorific effect produced. The advantages attending the use of this kind of fuel are so manifest that we are surprised that it is not making even more rapid strides than we see it actually making. The furnace requires no watching. When once lit it will burn for days and weeks without

a couple of taps. It might, at first sight, be supposed that danger attended the use of this fuel. Several persons have had their whiskers singed and their faces scorched, it is true, from explosions taking place in the furnace. However, in all cases, the sufferers have acknowledged that it was their fault, and have shown no apprehension of a similar accident happening a second time.

We now come to a paper by Mr. Reed, the Chief Constructor of the Navy, the subject of which was "Long and Short Iron-clads." This paper was prefaced by a statement of the length and breadth of the longest of our wooden line-of-battle ships and frigates, and some of the ironelads. It appears, from this, that the "Warrior," which is 380ft. long is 80ft. longer than the longest of our wooden frigates. The object sought in adopting this extreme length, was the driving a great weight of hull at a good speed, with proportionally moderate engine This end, Mr. Reed allows, was successfully accomplished; but, he asks, "Don't you pay away with the one hand what you receive with the other?" His own opinion he gives in these words:-" It is unwise to make an ironclad very long, large, costly, and unhandy, in order to effect a comparatively small saving in the engine power."
It has been Mr. Reed's duty to design ships of much more moderate dimensions. The "Bellerophon" may be taken as the type of the new class of "short ironclads." Its length is 300ft. The official reports on the experience with the two classes tell us that the short ships, with a slight increase of engine power, attain as good a speed as the long ships; that in turning power and general handiness, whether under steam or sail, the short ships have a decided superiority. while the great saving in the prime cost of the hull much more than compensates for the increased cost of engines.

Scientic writers, Mr. Reed remarks, generally ignore the weight of the hull of a ship, when discussing the form of water lines best suited for given speeds. This, of course, must lead to error. A merchantman may advantageously be long and fine, but in an ironclad, whose whole length must be armoured, an increase in length leads to a corresponding increase in the armour to be carried. An instance will better point out the conclusions which should be drawn from this fact. No less than 80ft. of the bow of the "Minotaur" is only partially water-borne. The excess of weight over buoyancy of this portion is 420 tons, and to carry this we require an increase of 13in. in the immersion of the water-borne midship portion of the vessel. This augments the area of the midship section, and in consequence the necessary engine power. Could not the same end be gained by a shorter and bluffer bow, which would allow of a decrease in the midship section? The answer to this query may be collected from the following fact:—In a six hours' run at sea, the "Minotaur," which had been out of dock nine days, made 14:165 knots, with 6,193-horse power, and the "Bellerophon," which had been twenty-one days out of dock, made 14.053 knots, with 6,199-horse power. This is a sufficient proof that there is very much in Mr. Reed's arguments, and a perfect justification for building the new class of ironclads.

Mr. Reed thinks that our experience warrants the assertion that "in armoured ships, as the extent and thickness of the armour to be carried are increased, the proportion of length to breadth should be diminished, and the fullness of the waterlines increased, and that the shorter fuller ship can be propelled at as great a speed as the longer finer ship, with about the same, or a little greater, horse power." As it is not possible to do justice to Mr. Reed's paper in a short abstract like the present, we have reproduced it verbatim on another column.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

THE ARTIFICIAL FORMATION OF ALIZARIN—TO
DETECT ULTRAMARINE OR ANILINE BLUE IN
WHITE SUGAR—A CEMENT FOR JOINING LEATHER
—LEATHER OIL.

YNTHETIC chemistry, the chemistry which occupies itself with the artificial production of bodies which are formed by what we may call natural processes in plants and animals, has made wonderful progress within the last few years. Among the most important of the triumphs in this branch of science, we may mention the artificial production of tartaric acid, the acid of the grape, and of coumarine, the odoriferous principle of the tonquin bean, by our countryman, Mr. Perkin; and also of sugar, or, at all events, a substance closely resembling sugar, by Carius. These are but a few of the remarkable discoveries made by chemists, who have engaged themselves with this line of research; but they serve to show the direction which the labours of some of our most advanced and intelligent chemists take. To-day, we have to record another brilliant discovery of this kind—the artificial production of alizarin; the principal colouring matter is madder root. It is not, however, the first time that the artificial production of this body has been announced. Some years ago, M. Roussin discovered, that by treating naphthaline with concentrated sulphuric acid, and a reducing agent, a deep red colouring matter was formed, which dyed mordanted cotton like alizarin, and the discoverer concluded that he has actually produced alizarin. Further research convinced him that he had made a mistake, and the colouring matter (now known in chemistry as naphtharazin), only producing dull colours, receives no applications. It is now announced that Graebe and Liebermann have succeeded in the production of alizarin from anthracene. This naphthaline, is found in the heavy semi-fluid portion of coal tar. As separated in an impure state, it is a yellow, soft, butter-like substance, but, when purified, it is obtained in colourless plates, with a silky lustre, very like naphthaline in appearance. Its relation to alizarin will be seen by a comparison of the formulæ of the two bodies.

C 14 H 10 C 14 H 10 O 4

Anthracene. Alizarin.

It is right to mention that the formula of alizarin, given above, is that assigned to it by Dr. Schunck. Other authorities ascribe to it the numbers C<sub>10</sub> H <sub>6</sub> O <sub>3</sub>, and, if these be correct, Other authorities ascribe to it it is difficult to see how it could possibly be formed from anthracene. The formula of the artificial alizarin is said to be C<sub>14</sub> H <sub>8</sub> O <sub>4</sub>, which represents the abstraction of two equivalents of hydrogen, and the addition of four equivalents of oxygen to the anthracene. We are not yet fully informed as to how this alteration is effected, but we are told that the artificial colouring matter comports itself exactly like the natural, and gives colours in every respect the same. Such discoveries as this are of immense importance, in a scientific point of view. Commercially, they are at present of little interest. Alizarin can be obtaine madder at far less cost than it can possibly be made from anthracene. But such transformations throw a light on the secret operations of nature, and point to a not far distant day, when man will be able, from simple inorganic materials, to build up for himself the most complex productions of organic life.

Continental sugar refiners have borrowed a notion from the laundress, and give an appearance of whiteness to their product by the judicious use of a little blue. Indigo has been employed for this purpose, but now, it is said, that artificial ultramarine, and also aniline blue, are occasionally used. To detect these, Dr. Reimann recommends that the sugar be dissolved in a small quantity of water, and the solution be allowed to stand for some time, whereupon the blue matter will settle at the bottom of the vessel. The deposit is to be separated, and then treated with diluted hydrochloric acid. If the blue colour is destroyed, and an odour of sulphuretted hydrogen evolved, the colouring matter is ultranarine. If the colour remain, the solution is to be filtered, and the deposit shaken up with some alcohol. Then, if a blue solution be obtained, the colour is aniline blue. It is as well to say that in either case the colour is quite harm-

less, and no one need be afraid to eat sugar a coloured.

A cement for joining leather, sufficiently strong to be used for driving belts and boot soles, may be found extremely useful. Such a cement is said by Stubenrauch to be made by mixing ten parts of bisulphide of carbon with one part of oil of turpentine, and dissolving in the mixture sufficient gutta-percha to produce a thick treacly fluid. Before it is employed, the surfaces of leather to be joined must be carefully freed from grease, and smoothed with a hot iron. The cement is then laid on both surfaces, which are now placed together, and kept firmly pressed until the cement is perfectly dry. It is obvious that boots, with soles stuck on in this way, must not be put near a fire.

In connection with this, we may mention Dr. Schwarz's account of a preparation extensively used in Germany for softening leather which has become hard. It is known as "leather oil," and is made, under the direction of Dr. Wiederhold, at Cassel. According to Dr. Schwarz, it is a mixture of oleic ether and train oil, scented with nitrobenzol, and may be prepared as follows: -Sixteen parts of eleic acid are mixed with two parts of strong alcohol, and then heated with one part of strong sulphuric acid, under suitable circumstances—that is, the vessel should be large, the acid should be added very gradually, and the mixture should be kept well stirred. On standing, after the mixture has become cold, the oleic ether will separate as a thinnish brown It must be decanted, and washed with warm water, to free it from sulphuric acid and excess of alcohol. Then it is mixed with an equal weight of train oil, and some nitrobenzol added to cover the bad odour. This preparation, we are told, penotrates the leather very easily, and gives it a remarkable suppleness. If not identical with the original, Dr. Schwarz states that it answers the purpose just as well.

# LONG AND SHORT IRONCLADS. By Mr. E. J. Reed, C.B.

In the design of our earliest ironclad frigate, the "Warrior," dimensions and proportions were adopted far exceeding those of the longest and finest wood ships which preceded her. The "Minotaur" class, designed in consequence of the desire to obtain complete protection, have even a greater proportion of length to breadth than the "Warrior," and are considerably larger; but in them, as in the "Warrior," economy of steam power was one of the great features of the design. Our more recent ships have less extreme proportions and dimensions, and in their design economy of steam power did not occupy, by any means, so prominent a place. Before proceeding to discuss the relative merits of long and short ironclads, however, it may be well to give the lengths and proportions of a few of our principal ironclads, and to compare them with those of our longest and finest wood-ships.

Ships.	Length.	Breadth.	Propor- tion.
Unarmoured:	ft. in.	ft. in.	
Longest three-deck line- of-battle ships Longest two-decked line-	260 O	61 0	4.3
of-battle ships	254 9	55 4	4-6
Longest frigutes	300 0	52 0	5-8
Armoured:			ĺ
"Warrior"	380 0	58 4	6.5
"Minotaur"	400 0	59 4#	6.7
"Bellerophon"	800 0	56 1	63
" Hercules "	325 0	59 0	5.5
"Monarch") turret	330 0	57.6	5.7
"Captain" ships	320 0	53 0	6-0

From these figures it will be seen that, in consequence of the armour plating of about 213ft. amidships, the "Warrior" was made 80ft. longer than the longest wood ships; and that complete protection in the "Minotaur" was thought to require an additional length of 20ft., making 400ft. in all. There can be no question that the objects kept in view by the designers of these ships—the carrying of a large weight of armour on a hull so formed as to be driven at a high speed with a proportionally moderate engine power—were very satisfactorily attained. The question arises, however, whether the objects on which the designs were based were themselves wise. My own opinion on the subject is well known, and may be briefly summed up in the statement that it is unwise to make an ironclad very long, large, costly, and unhandy, in order to effect a comparatively small saving in the engine power. It has been my duty to carry into practice principles of design totally opposed to those exemplified in the "Warrior" and "Minotaur."

The new method of design received its first

<sup>\*</sup> Read before the Institution of Naval Architects.

illustration in the "Bellerophon," and in that vessel has undergone a series of trials, the results of which are of a most satisfactory character. It has also been applied to the "Lord Clyde" and "Lord Warden," which are 280ft. long and 59ft. broad, the proportion of length to breadth being about 4½ to 1, and in these short, bluff, completely protected ships, has proved quite as successful as in the "Bellerophon." All our recent ironclads have similar moderate proportions, and the ship last tried, the "Hercules," has afforded another, and most striking, illustration of the benefit resulting from this course. Our experience with long and short ironclads, and the official reports of trials of speed and turning power, may, I think, be fairly stated as follows:—That the short ships may be driven as fast as the long ships by a moderate addition to their engine power; that in turning power and general handiness under steam and sail the short ships are much superior, and that the great reduction in the prime cost of short ships much more than makes amends for the addition to the steam pewer. In thickness of armour, and in character of armament, I need hardly say that the more recent ships are superior to the long ships first built. Without discussing further the actual trials of long and short ironclads, I shall proceed to consider the subject from a more theoretical point of view. Scientific writers upon the forms and resistances of ships have generally recommended the adoption of forms of least resistance; and have taken no account whatever of the effect which the weight of the material in the hull should have upon the form of a ship. The most cursory glance will, however, be sufficient to show that this generalization cannot include the designs of all ships. Take, for example, the vastly different conditions to be fulfiled in a merchant ship and in an ironclad war ship. The former is designed to carry cargo economically, and the weight of hull forms a comparatively small function of the total displacement; while th

to a corresponding increase in the area of the surface to be armoured, and in the unproductive weight to be carried; while a reduction in the length leads to a considerable decrease in that area, and in the total weight of armour.

The impossibility of correctly prescribing any general form of ship, in disregard of the armour, will exhibit itself even more strikingly if we consider independently ene end of a ship, say the bow or entrance. To fix our ideas, we will take the case of the "Minotaur," for which ship it has been found by actual calculation that in still water the weight of the first 80ft. of the bow exceeds its displacement by about 420 tons. This excess of weight must clearly be floated by the central part of the ship, where the buoyancy exceeds the weight, and the length of this part being 250ft., while its mean breadth is about 76ft., its immersion must be increased by about 13in. In consequence of the unsupported weight forward This additional immersion increases the area of the midship section which has to be propelled through. The water by from 60 to 65 square feet. Now, let us imagine this bow to be so shortened and shaped—on the one hand increasing its buoyancy, and on the other diminishing its weight—as to produce an equilibrium between its total weight and buoyancy. No doubt by making it bluffer we shall increase its resistance to motion through the water, but we shall at the same time lighten the burden upon the central part of the ship, and reduce the total area of the midship section to be driven as well as the total weight. It is easy to see that by this means we may succeed in getting the same speed with a given power, as would have been obtained by employing the longer and finer, but much heavier bow. This is the essence of the principle which I have laid down, and carried out in practice.

In the design of all merchant steamships the conditions to be fulfilled area os similar, and the proportion of weight of hull, equipment, and carried out in practice.

In the design of all merchant

say, estimated from the two formulas,

(Speed)<sup>3</sup> X Midship Section Immersed

Indicated horse power

(2) Constant= (Speed)<sup>3</sup> ×(Displacement)
Indicated horse power

These formulæ are always used in calculating the results of the trials of ships of the navy. In them it is assumed (1) that, within certain limits, the resistance to a ship's motion varies as the square of the velocity, and that, therefore, the propelling power must vary as the cube of the velocity; (2) that the resistance also varies, cateris paribus, as the area of immersed midship section in the first formula, and as the two-thirds power of the displacement in the second formula; (3) that the indicated horse power bears a constant ratio to the useful work of the engine, i.e., to the power actually available for propulsion. These assumptions are incomparing performances, and in determining the engine power needed in a new design.

I may remark in passing that the method of calculating the horse power just referred to is much surprise when it is remembered that the difficulties of surprise when it is remembered that the difficulties surprise when it is remembered that the difficulties of surprise when it is remembered that the difficulties surprise when it is remembered that the difficulties of the hand, a glance through the elaborate table of the sections ship, similar in form and proportion to the new design, and from the constants obtained by this ship to calculate the horse power required for the estimated speed, with a very fair amount of accuracy.

While recognizing the value of the constants, that the

the estimated speed, with a very fair amount of accuracy.

While recognizing the value of the constants, however, I cannot entertain the opinion that they should form the sole standards by which all steamships, armoured as well as unarmoured, should be judged. Such an opinion virtually amounts to a belief that the chief aim of the naval architect ought to be the lowering of the proportions borne by the indicated horse power to the speed attained, to the midship section immersed, and to the displacement. As far as form alone is concerned, this view is no doubt correct, but obviously, if carried out in its entirety, it would lead to the construction of ships that would carry no weights except those of the propelling apparatus. This is, of course, an extreme case, and it may be thought unfair to argue from it the folly of the system as a whole. But if economy of steam power is the chief desideratum in ship design, the case imagined is also the fullest development of the principle; and if we once admit other considerations besides form—such as cargo-carrying power, first cost, and handiness—the failure of the constants as criteria is tacitly acknowledged.

There can be no doubt that in merchant ships increased proportions and fineness of form have led.

constants as criteria is tacitly acknowledged.

There can be no doubt that in merchant ships increased proportions and fineness of form have led, and do lead, to increased carrying power, and to economy of steam power; and that in such cases the constants of performance have higher values. The lightness of the hull would, in my opinion, tend to produce these results, and I have previously stated that for merchant ships—and it is true also for unarmoured war ships—the constants are very fair standards of excellence. But with ironclad ships, if a similar mode of comparison were followed, we should in many instances be comparing vessels of which the armour was of extremely different degrees of efficiency, and should, at the same time, wholly exclude this important fact from our consideration.

ration.

For example, if the "Warrior" and "Bellerophon" were compared, we should have the former with comparatively thin armour plating extending over a little more than half the length; and the length at the water-line, besides having armoured central and bow batteries. It would obviously be most delusive in comparing these ships to waive all consideration of these facts and to take constants of performance as the sole criteria. In fact, such a course would be equivalent to requiring that the proportion of weight of hull (including armour) to the displacement should be considerably greater in the shorter than in the longer ship. At the same time the other most important points connected with first cost, character, and weight of armament and handiness, would be entirely neglected.

In short, constants of performance can only be of

In short, constants of performance can only be of use in comparing the merits of two ironclads when there is similarity, or at least equality, of construction, armour, and armament; and when this condition is satisfied, the conclusions based upon the values of the constants must be supplemented by considerations of cost and handiness. The merits of ironclads ships do not consist in carrying a large proportion of weights to engine power, or having a high speed in proportion to that power; but rather in possessing great powers of offence and defence, being comparatively short, cheap, and handy, and steaming at a high speed, not in the most economical way a high speed, not in the most economical way a high speed of norder to decrease the weight and cost, adopted in order to decrease the weight and cost, and to increase the handiness. It must be obvious that if a ship 300ft. long, plated all over with given armour, carrying a given armament, and costing say armour carrying a given armament, and costing say armour cost of the speeds attained having alone the time of trial having been neglected. Such a tent that on this, the previously described always should et ala 400ft. should have alwest. It is in the other hand,

a cost say of £380,000 for no other object than that of driving the greater weight at the same speed with about the same power; in other words, for the mere purpose of raising the constants.

It may, perhaps, be objected to this statement that the trials of actual ships do not show that a ship 300ft. long can be driven at the same speed, with about the same power as a ship 400ft. long, when the armour is equally efficient in the two ships. Now, I need hardly say, that in dealing with speed trials great care is required in order to ensure a fair comparison of the performances of any two ships. So many causes of difference exist, that until it is known that they are either inactive, or else acting similarly, in the ships compared, the comparison is of little worth. The quantity of the condition of the engines, and the state of the bottom, as well as the force of the wind and condition of the sea, are the chief causes of error in such comparisons; and the reports on the performances of our ironclads prove that greater varieties of speed are due to these, so to speak, secondary causes, than are shown to exist when the ships are first tried on the measured mile. This is a most important fact, requiring to be borne in mind when the policy of our naval construction is being discussed; for the present I only refer to it as connected with the speeds actually attained on trial.

With these prefatory remarks I desire to introduce to your notice the results of a series of

refer to it as connected with the speeds actually attained on trial.

With these prefatory remarks I desire to introduce to your notice the results of a series of trials which took place in the spring of 1868, and which were conducted in such a manner as to eliminate, as far as possible, the effects of these sources of error; care being taken to ensure equally good coal and stoking, the bottoms being cleaned almost immediately before the trials took place, and the engines, as the trials showed, being in excellent condition. The ships tried were the "Minotaur," "Bellerophon," and "Warrior"; but for the present I shall confine attention to the two first-named vessels, as their performances will throw some light on the point now under discussion. It has been found by actual calculation that the weights per square foot of the protecting material—armour and backing—in these ships, when uniformly distributed over the surface of the side from the lower edge of armour up to the upper deck, are very nearly identical: so that it may fairly be assumed that if the "Bellerophon" were completely protected she would have quite as strong armour as the "Minotaur," the excess in thickness of the skin plating in the "Bellerophon" over that in the "Minotaur" being put into armour. Hence, it follows that these ships may be taken as representatives of the 300ft. and 400ft. ships previously referred to.

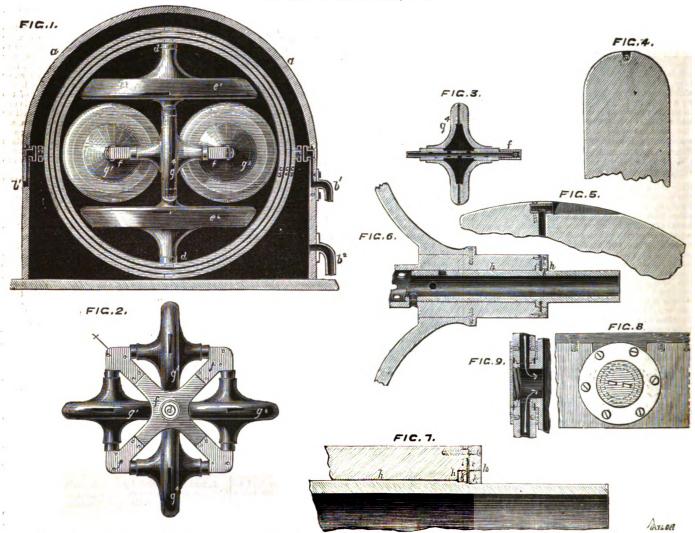

Before being tried by a six-hours' run at sea, the ships were put over the measured mile in Stokes.

Hence, it follows the 300ft. and 400ft. ships previously referred to.

Before being tried by a six-hours' run at sea, the ships were part over the measured mile in Stokes' Bay, where the "Minotaur" attained a speed of 14.411 knots, with an indicated power of 6,702-horse power, and the "Bellerophon" realized 13.874 knots, with an indicated power of 6,002-horse power. With a greater power by 700-horse power by 700-horse power with therefore, the "Minotaur" beat the "Bellerophon' by about half a knot. This trial does not help us much in our investigation, but the six hours' trials are of exactly the right character for our purpose, since on them the indicated horse powers were, as nearly as possible, identical. On this trial, when the "Minotaur" had only been out of dock nine days, she made 14.165 knots with 6,193-horse power; and on a similar trial the "Bellerophon," which had been twenty-one days out of dock, made 14.053 the Navy remarked in his report on these trials, "the 'Bellerophon' had the disadvantage of having been twice as long in the water as the other two ships, and at this time of the year (the spring) the ships, and at this time of the year (the spring) the dentical with that of the "Minotaur," when the identical with that of the "Minotaur," when the other hand, it is right to state that on this, the only occasion when such ships have been tried under principle that 300ft. and 400ft. ships of the character previously described always should steam at the previously described always should steam at the other hand, it is right to state that on this, the other hand, it is right to state that on this, the other hand, it is right to state that on this, the other hand, it is right to state that on this, the other hand, it is right to state that on this, the other hand, it is right to state that on this, the other hand, it is right to state that on this, the other hand, it is right to state that on this, the other hand, it is right to state that on this, the other hand, it is right to state that on this, th Before being tried by a six-hours' run at sea,

# THE WHIRL-WHEEL STAR POINTER.

BY MR. J. F. BOURNE, C.E.

course is obviously incorrect, as the connection between horse power and speed is indissoluble; and it has been truly said that complaints of fallings off in speed, which were really due to smallness of horse power, amount to complaints that the hull did not drag the engines along at a greater rate than that at which they were working. The fact is that all the long ironclads have engines of the old type, which had been gradually improved upon, until—apart from the preat consumption of fuel—it had been made to approach perfection, and not only was the development of the guaranteed power ensured, but in many cases that power was considerably exceeded. The recent short ironclads, on the other hand, have the new type of engines with surface condensers, superheaters, and other novel arrangements, which, like all newly-introduced mechanical contrivances, are liable to occasional failure that could hardly have been foreseen, and can be easily remedied, but that, for the time, cause very mistaken notions of their true character. As experience is gained in the construction and working of these improved engines, they, like the older type, will no doubt be perfected; but, at present, their performance is not nearly of so certain a character as that of the more wasteful type which preceded them. It has happened, in consequence of this fact, that on some occasions the power developed in, and the speed obtained by, our short ships at sea, have fallen considerably below the corresponding results on the measured mile trials; and in published reports of these so-called failures the low speeds have been given without any mention being made of the want of engine power. I have already referred to the unfairness of this course, and need only add that the results of the trials of all the short ships may be summed up in the statement that, when the engine power has reached the amount guaranteed the estimated speed has been attained, but that when the power has fallen off the speed also has necessarily declined. It is not the function

(To be continued.)

THE WHIRL-WHEEL STAR POINTER.

WE illustrate herewith an apparatus which has been designed by Mr. John Fred. Bourne, M. Inst. C.E., with the view of meeting a most important requirement in ocean navigation. It is an instrument for the purpose of indicating the true north, and for ascertaining the latitude and longitude of a ship at sea, with facility and accuracy. The proposition is to avoid all errors accuracy. The proposition is to avoid all errors of the ordinary magnetic compass, by the use of a mechanical pointer, constructed upon the principle of the gyroscope. It is unquestionably a production upon which much time and thought have been expended, and appears to be exactly what is required for the purpose. Whilst giving Mr. Bourne every credit for the ingenuity of his conception, we must observe that it has not yet passed from the realms of theory into those of practice—scarcely of experiment—which alone can deter mine its real value. As it stands, however, Mr. Bourne has generously placed the idea at the disposal of the public through our columns, and we shall be glad to find the matter open up a discussion in our pages, and lead to experimental trials, as well as to practical results. We cannot do better than describe this invention, by means of the annexed copy of a communication which Mr. Bourne sent to the Astronomer Royal, whose opinion upon its merits, we are enabled, by the courtesy of Mr. Bourne, to annex. As suggested by Professor Airy, we commend Mr. Bourne's highly ingenious notion to the consideration of our leading mechanical engineers, who will confer a boon upon our navy and mercantile marine if they can develope the inventor's proposition, and bring it to a practical issue. Mr. Bourne's letter to Professor Airy bears date October 16, 1868, and is as follows:-

"Dear Sir,—On the last voyage I made round the Cape of Good Hope, in the 'Celt,' Captain Baynton, in 1866, the deviation of the steering compass, on one course, was as much as 60deg. I have, last month, had a note from Captain Baynton in which he says 'the maximum deviation of the "Celt's" compasses is 66deg. west, with her head to the westward off the Cape.' Seeing Captain Baynton so often employed in eliminating these errors, whilst working out his course, and reflecting on their danger, especially in the hands of a less careful and skilful commander, it occurred to me that the only way to avoid them was to have a standard compass on board, which should be entirely free from magnetic error, and which, consequently, could not be influenced either by the magnetism of the earth or by local attraction. It would be necessary, therefore, to dispense with the magnetic needle. It occurred to me that the stability of the plane of rotation is the proper principle to work upon, and I have been engaged upon it, at intervals, ever since.

"I beg leave to lay a rough sketch of the result before you, with a request that you will kindly oblige me by saying whether, in your opinion, my theory is correct or not. It is in some measure supported by very imperfect experiments, but it is evident that, to be of any real service, a trial must be made in such a manner as is not likely to be undertaken, unless the theories be confirmed by the most competent authority. Having resided for the greater part of my life in distant lands, I was not aware that the principle had ever been applied to any similar purpose, but have since found that Professor Piazzi Smyth tried it rather successfully on board Mr. Stephenson's yacht, the 'Titania,' in 1856, to obtain stability for instruments for astronomical observations at sea.

"My chiest at first was proper to desire a

"My object at first was merely to devise a 'whirl-wheel compass,' free from magnetic deviation, but, in pursuing the subject, it soon became evident that the instrument, if it answered this purpose at all, might answer other purposes equally well. I think I am right in saying that it can, when accurately constructed, be made to show, by inspection, the latitude of the ship's position,

and sidereal time for the calculation of the longitude. The main desideratum is to obtain an exceedingly rapid, regular, and constant rotation of the heavy planes employed. For this purpose, I propose to use compressed air, operating, by reaction, on the wheels running as much as possible in vacuo. The accompanying sketches will be sufficient to explain to you the mode in which I propose to construct the instrument and some of its details:—

"Fig. 1 represents the apparatus in elevation in one of its positions explained hereafter. a a is a strong airtight chamber (in section) of any convenient size and shape. It might be an open metal framework, glazed with small hexagons of strong plate glass. It should be placed in the engineroom of a steamer, and be provided with a reflecting tube, communicating with a dial plate on deck.  $b^1$   $b^1$  are pipes communicating with a force pump, worked by the engines of the ship, or by a donkey engine, to supply compressed air to the machinery of the instrument.  $b^2$  is a pipe communicating with an air pump, worked in the same way.  $c^{-1}$   $c^{-2}$   $c^{-3}$   $c^{-4}$  and  $c^{-5}$  are hollow gymbal rings, with hollow pivots for the passage of compressed air.  $c^{-1}$   $c^{-2}$  (in section) are horizontal, in the usual manner.  $c^{-3}$  is weighted at bottom, so as to hang in a vertical position.  $c^{-4}$  lis also vertical, being pivoted at top and bottom into  $c^{-3}$  so as to revolve in a horizontal plane.  $c^{-5}$  swings on horizontal pivots, so as to be placed at any angle with the horizon. The main pivot d is a tube passing through the diameter of  $c^{-5}$  at right angles to its pivots. This tube is accurately turned, so as to form the pivot, round which the wheels e e, and the frame f move. It has holes or ports, to admit compressed air into the wheels e e, and the frame f move. It has holes or ports, to admit compressed air into the wheels e e, and the frame f move. It has holes or ports, to admit compressed air into the wheels e e, and the frame f move. It has holes or ports, to admit compressed air into the wheels e e, and the frame f move. Each wheel is hollow, but heavy in its periphery, for the exit of compressed air, so as to produce reaction, and with valvular stuffing boxes, described hereafter.

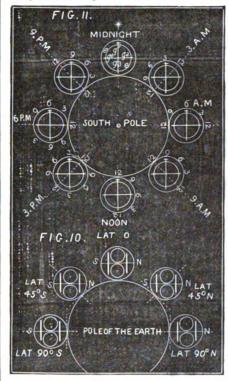

"In figs. 1 and 2, f f is a hollow metal X frame,

"In figs. 1 and 2, ff is a hollow metal X frame, bored through the centre of its four arms, so as to turn on the pivot d; it is provided with airports and stuffing boxes like those of ee.  $g^1g^2g^3$  and  $g^4$  are four heavy wheels or 'gyroscopes,' turning on tubular centres let into the ends of the arms of ff, and are fitted like e. Fig. 2 shows the framework f and the four wheels in plan. Fig. 3 shows one of the wheels in section, where f is a section of one end of an arm of the X frame. The ports in the tubular pivot, and in the axle of the wheel, must be so cut that one or other is always open for the admission of compressed air into the wheel. Figs. 4 and 5 are drawn to a larger scale, and show the tangential orifices in the periphery of each wheel by which to obtain reaction. By turning with a key or turnscrew a small tube fitted into the orifice, a port in the tube is opened or partially closed so as to regulate the emission of air, and, consequently, the speed of the wheel. As soon as the air escapes from the orifice, producing reaction, it is carried off by the air pump, leaving as strong a vacuum as possible.

"Fig. 6 is a portion of fig. 3 on an enlarged scale, and fig. 7 is a portion on a still larger scale to exaggerate the bearing and working surfaces h h; and to show how the compressed air, trying to escape, is checked by the flat steel ring (shown in section at i) running sufficiently loose in a groove turned to receive it, the ring being forced by the pressure of air upon the opposite smooth surface, like the slide valve of a steam engine upon the valve face. The rings or collars k k are forced very tightly into their proper places and secured if necessary. Figs. 8 and 9 show how the hollow gymbal pivots may be made airtight by similar rings, but this is open to improvement.

"The following is the method of using this instrument:—Set the main pivot d d parallel with the axis of the earth by directing it to its proper point near the pole star. Its angle with the horizon will then show the latitude of the place, as seen in fig. 10, where the dotted tangents show the horizon, and S.N. the main pivot (d d, fig. 1). At 90deg. N. and 90deg. S. the instrument will appear in elevation as it does in fig. 1, the main pivot d d being, at the poles of the earth, perfectly vertical. Set the wheels into rapid motion, by admitting highly compressed air into the wheels through the gymbals. Now, on board a ship running down a meridian of longitude, the main pivot d d will, of course, on account of the stability of the planes of rotation of the wheels, retain its true position parallel with the earth's axis, but will appear to the spectator to assume the positions, as seen from the centre of the circle repre-

senting the earth in fig. 10. If the gymbal ring  $c^3$  be provided with a glass globe accurately divided, or with a sphere of graduated rings, the latitude will be read off, by inspection of the degree to which the pivot points. Then, if the main pivot d d be parallel with the axis of the

earth, the main wheels  $e^{-1}e^{-2}$  are revolving parallel with the plane of the earth's rotation, and the wheels  $g^{-1}g^{-2}g^{-3}g^{-4}$  are revolving at right angles to the plane of the earth's rotation. Thus, on the same principle of their stability, any point of their frame, as  $\dagger$ , fig. 2, will, of course, if directed to a fixed star one day, maintain the same direction, and appear to revolve on its axis d d in twenty-four hours sidereal time, as shown in fig. 1:

"I have not entered thus fully into the description of the action of the instrument for your information, as you know, better than I do, what it ought to be, and to do. But, as I find that the principle is little understood, even by men of high standing as mechanics, I may perhaps be excused in seeking to obtain confirmation of my theories, before asking any one to spend time and money in trying to carry them into practice. I am fully aware that very great accuracy of workmanship will be needed; and the whole of the instrument contained within the ring  $c^3$  must be in perfect equilibrium. But, if the whole be made of steel, for durability of working parts, and homogeneity of substance, and of sufficient size (say, with wheels from 1ft. to 3ft. in diameter), and if the parts be shaped by machinery accurately constructed for the purpose, and with minute gauges, I do not think that difficulty is insurmountable. The principle being admitted, the end will be attained. I think, by injecting the lubricating material with the compressed air.

"The speed of the wheels must be so regulated, that the speed of any one wheel may not be so excessive as to cause it to overpower the stability of all the others, so as to produce the precessional motion seen in the gyroscope. But I think this difficulty will be overcome in an instrument of sufficient size and power. And the power may be increased to any required extent by the increase of size or speed in the pumps. By the use of compressed air, the power and speed will be most easily regulated. It is this application of the constant power to wheels placed in such a position, with means of regulating the speed, for which only I claim any credit. The principle, and its application in other forms, is well known to you.

"Two or more of these instruments in the engineroom of an iron steamer, and under the charge of
the engineers, would form standard compasses of
great value, by which to check the magnetic needles
of the steering compasses, and as a check upon one
another, and to be checked frequently by azimuths
and observations. Without gymbals, and as an
instrument fixed to the latitude of the place, would
not the frame f f and its wheels g g form a useful

star-time measure or astral chronometer for an observatory? If made of sufficient size, with great accuracy, as to fitting and equilibrium, with long bearings and antifrictional rollers, which may be easily arranged, it seems to me—accustomed as I am to the construction of locomotive engine and other machinery and instruments—that there would be no insuperable difficulty opposed to it. Even if the instrument cannot at first be constructed with such accuracy as to be absolutely correct; yet, if its error be constant and regular, so as to be readily allowed for, like that of a chronometer, and not arising from local causes, the same end, it seems to me, will be attained.

The flow of water would not be sufficiently rapid to produce the required speed of rotation; but steam might be used instead of compressed air. This and electro-magnetic or magneto-electric engines have been considered by me. But the compression of the air may be so exactly regulated, and it—air—is so simple in its application, that, for this purpose, it cannot be equalled.

this purpose, it cannot be equalled.

"I have the honour to be, Sir,

"Your most obedient servant,

"John Fred. Bourne, M. Inst. C.E."

"Royal Observatory, Greenwich, "London, S.E., November 13, 1868.

"Dear Sir,—It is but lately that I have found time to examine the papers which you sent me under date of October 16. I am very much struck with the ingenuity and the obvious efficiency of the method by which you propose and to maintain the rotation of your heavy dises. The principle of making the rotating plane, in fact, produce its own maintaining power, by the intromission of strong gas through the axis, and its discharge at the circumference, is very happy. I think that if this had been superadded to Professor Piazzi Smyth's other contrivances, it would almost have induced me to recommend a trial of his principle in some of our large mail steamers (the only class of vessels in which I thought it likely to be introduced), for the purpose proposed by him, namely, the support of telescopes, &c. I suppose that the enlargement of the pivots for the passage of gas might not necessarily be so great as to produce unmanageable friction.

"But you aim at a much higher object, that of maintaining a plane in a position parallel to itself (as in space) for whole months. I really cannot give any reason, theoretical or experimental, against the success of this. I do not see, in the mode of action of the various parts, anything which tends to change the position of either rotating disc in a definable direction as the vessel pitches or rolls or changes her longitude or latitude. Yet I feel a strong assurance that it never could preserve its position with the accuracy which is required. The wear must be considerable, and wear infallibly introduces irregularity. A ship makes perhaps 3deg, in a day. Can you hope that this instrument will preserve its position for a day within 3deg.? I think not, but I cannot tell why.

think not, but I cannot tell why.

"If I were a wealthy engineer, I would certainly try the construction in a home experiment. Your proposed method of maintaining the rotation appears completely to remove what had always seemed to me the insuperable difficulty in giving fair play to the principle of the rotating disc. Can you not make an impression on some of our great mechanists, to whom the expense would be insignificant?

"I have treated this all along as a purely mechanical arrangement. For the want which suggested it to you, namely, that of correct magnetical compasses, there really is no need of any special contrivance. A captain who understands the principles of compass-correction, can at any time, with only two bearings of his ship, so adjust his magnets that no sensible error will remain.

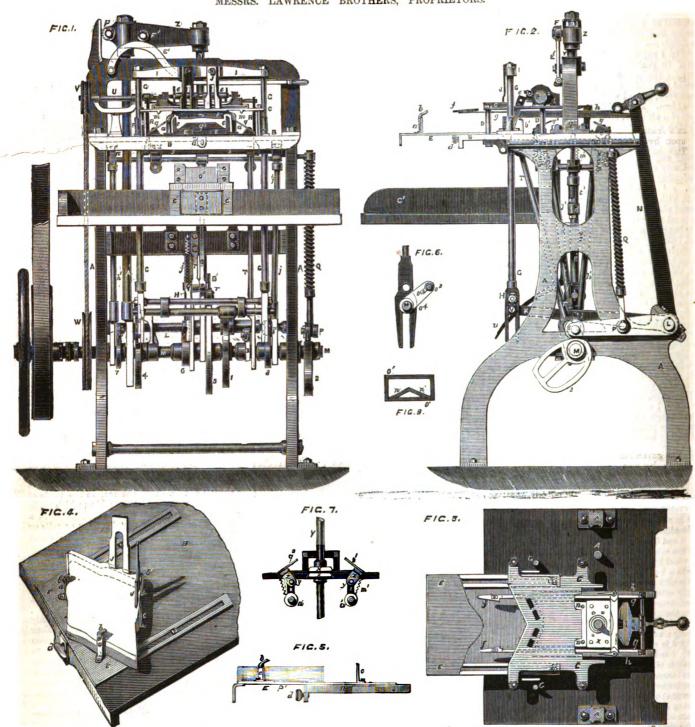

"I return the packet of papers to the address which you have given me, namely, to the care of Messrs. Budden, Jennings, and Co., 48, Fenchurch-street.

"I am, dear Sir,
"Your faithful servant,
"(Signed) G. B. Airy.
"J. F. Bourne, Esq."

An American paper states that in consequence of the demand for hair of peculiar colours and shades a new branch of "kleptic industry" has sprung up in New York. It appears that the hair thief abounds in the horse cars of the city, where the excuse of putting his elbow on the window enables him to operate with greater ease; but he is also to be found in every place of public gathering, the church included. The tresses dangling behind the head are his easy prey.

# SELF-FEEDING ENVELOPE FOLDING MACHINE.

MESSRS. LAWRENCE BROTHERS, PROPRIETORS.

# SELF-FEEDING ENVELOPE FOLDING MACHINE.

WE would direct our readers' attention to a very complete machine, by which the feeding, gumming, stamping, creasing, folding, delivery, and collection of envelopes are performed with the aid of only one attendant, who has ample time to band the envelopes so produced. The credit of inventing this machine is due to Mr. G. H. Reay, of New York, by whom it was patented in the United States, England, and on the Continent. The patents for Europe are, however, the property of Messrs. Lawrence Brothers, of 22, Basinghall-street, who are supplying them to manufacturing stationers. The machines are manufactured in England for the proprietors by Mr. John Gough, of 42, Kirby-street, Hatton-garden, at whose works we recently examined one of these compact and ingenious machines.

To thoroughly appreciate the advantages these machines present, our readers must bear in mind that other machines require three attendants to

perform the operations carried out by these, which require one attendant only. There is the attendant to feed with one blank at a time; and as ordinary machines deliver the envelopes simply creased, another attendant must place the flaps of the envelopes in proper order and gather them up, whilst a third attendant is required to band them. In the machine we are about to describe, the attendant sits down in front and places in the proper receptacle a certain number of blanks, regulated according to their substance; the apparatus picks up the blanks singly and conveys them to the creasing box, and, during their progress, they are stamped, if so required. After having been creased, the envelopes are, by a double action of the plungers, most securely and correctly fastened and folded. After leaving the plungers, they are mechanically collected and delivered to the attendant in symmetrical order ready to be banded. Thus, from the time the blanks are delivered to the machine till the perfect envelope is turned out, the attendant has nothing to do with them, which leaves ample time to band them up.

This machine is represented in front elevation at fig. 1 of our engraving, whilst fig. 2 shows the apparatus in side elevation. Fig. 3 is a plan, with the upper framing removed, to show more clearly the apparatus for feeding and pressing. A is the main frame of the machine; it carries near its upper part a table B, above which is a plate C supported by columns or pillars D on the table B. The plate C is perforated for the passage of the lifters. The table B also carries near the front end another plate E, free to be moved in and out as required. This plate and a portion of the table B are shown on a larger scale in isometrical view in fig. 4, and inside view in fig. 5. The envelope blanks are placed on the plate E when drawn out (as shown in figs. 2, 3, and 5), and are kept in place by projections a on the plate. The projections are fitted at top with bent springs b b for a purpose to which we shall presently refer. When the plate E has been supplied with a number of blanks, it is pushed in, as shown in fig. 4, until the blanks come against projections c c on the table B, when they are in position for being fed

singly into the machine. The plate is then secured

by means of a thumb screw d.

The table B carries guides F for vertical rods
G G which pass through it. These rods are forked at bottom to embrace a horizontal rod H, while at top they are connected by a cross beam I from which lifters J J depend. These lifters perform which lifters J J depend. These lifters perform the double purpose of gumming the envelope blanks and of lifting them one by one from the supply plate E. The lifters are forked at bottom, and the forked ends are supplied with gum from the rollers e e, which have a to-and-fro motion imparted to them. Immediately after being gummed, the lifters J J fall, come in contact with and take up the uppermost blank, which adheres to their gummed surface. The lifters J J receive up-and-down motion from a rocking lever K centred up-and-down motion from a rocking lever K centred on a shaft L at back of the machine, and acted upon by a cam I on the main driving shaft M. This cam is double, that is, it is formed so as to produce a double action; it first raises the lifters J J a certain height (after their forked ends have been gummed and have taken up a blank) in order that the blank may be released by coming in contact with the under surface of the plate C. The bent springs b b on the projections a a of the supply plate E at the same time bend down or curve the end flaps of the blank to ensure its being caught by fingers. The second portion of the cam 1 then acts to raise the lifters J J still higher when the gumming rollers e e come under their when the gumming rollers e e come under their forked ends to supply them with gum for another blank. In the meantime, the first blank has been seized by fingers f f on the ends of slide rods g g, which are moved to and fro in a framing h fixed on the back part of the table B. This movement is effected by a weighted rod N, which connects a cross bar O of the slide rods g g to the back shaft L. The weight on the rod N prevents all jar and shock in this part of the machine. The shaft L receives motion from a lever P on its end, acted receives motion from a lever P on its end, acted upon by a cam 2 on the main shaft M. The lever P is furnished with a spring rod Q to keep a roller i carried by the lever on the face of the cam. The fingers ff are undercut at the back, as seen in fig. 2, in order that in their backward motion the undercut portions may come against the blank and carry it to the creasing apparatus.

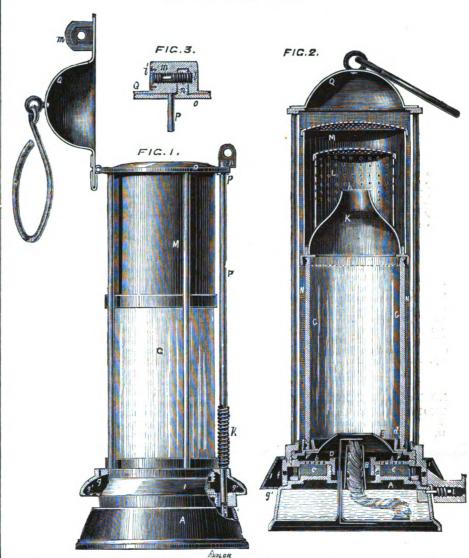

The gumming rollers e e receive their to-and-fro motion by means of levers R R connected to a cross bar S under the table B; the cross bar S in its turn receives motion from a nearly vertical rod the lower end of which is forked and furnished with a roller j, which rides upon and is acted on by a cam, 3 on the main shaft M. The gumming rollers e e are fitted in a frame which moves to-andfro in guides on the plate C; any gum which may fall from the rollers is caught upon this frame. The rollers are composed of printer's composition covered with india-rubber. They receive their supply of gum from another roller or doctor k, which rotates partly in a box l containing the gum. Which rotates partly in a box t containing the gum. The doctor k is made to rotate by a projection on its axis being acted on by a pin on the shaft U carried by a framing on the table B. This shaft receives motion through a pulley V over which a band passes to another pulley W on the main shaft M. The gum box l is provided with a scraper or expected to regulate the supply of Vspreader to regulate the supply of gum.

The plate C has two ribs m m formed on its under side, which, as the envelope blank is being carried back by the fingers ff, as before explained, keep the end flaps slightly curved downwards, in order that the blank may be presented in that position to the plunger. Beneath the plate C is an inclined plate n which supports the body of the blank while being carried to the creasing box. Immediately the blank is brought over the creasing box. ing box, a top plunger X comes down upon it and drives it into the creasing box, whereby the four flaps are creased or brought into a vertical position; the plunger X then ascends. Up and down motion is imparted to this plunger through a vertical rod Y connected to a horizontal beam Z above the machine. The beam Z is again connected to another vertical rod A <sup>1</sup> forked at its lower end, and carrying a roller o which rides on a cam 4 on the main shaft M, except after the plunger X in its down stroke has reached the envelope blank. If the pressure of the plunger is not sufficient, greater pressure is caused to be exerted by another roller o<sup>2</sup> which rides over the roller o at every revolution of the main shaft. This additional roller or is carried on a pin adjustable in a slot or (see the detached view, fig. 6), in an arm or crank or 4 on the main shaft. The beam Z is guided in its motion by a roller which bears against a projection on the upper part of the main frame A.

When the top plunger X ascends, two fingers q q

#### SAFETY MINERS' LAMP.

BY MR. STORY HORN.

come down upon and fold the end flaps of the blank; then another finger q 1 comes down upon and folds the back flap, the inner surface of which has been gummed; a fourth finger  $q^2$  then comes down upon and folds the front flap. Simultadown upon and roles the front hap. Simultaneously with the coming down of the two end fingers q, a bottom plunger  $X^1$  is made to ascend to the bottom of the creasing box to support the blank. Immediately after the folding of the flaps by the four fingers, the top plunger X again descends and carries another blank into the creasing box. The fingers then retire by means of mechanism we shall presently describe just before the plunger X in its down stroke would press upon them, and this plunger exerts pressure upon the edges, and still printinger exerts pressure upon the edges, and still greater pressure upon the gummed portion (owing to the peculiar construction of the face of the plunger) of the envelope, the folding of which has just been completed. The finished envelope and the creased blank are now momentarily held between the two plungers X X 1.

It will thus he seen that each blank remains in

the creased blank are now momentarily held between the two plungers X X \(^1\). It will thus be seen that each blank remains in the creasing box during two descents of the top plunger X. The bottom plunger X \(^1\) is made to rise and fall, by means of a cam 5 on the main shaft M, against which a roller \(^r\) on a forked vertical rod B \(^1\), which carries the plunger X \(^1\) bears. The finished envelope is caused to fall from the top of the plunger X \(^1\) by means of two projections, which in the down stroke of this plunger pass through slots, and tilt the back of the envelope, which falls edgewise down a shoot D \(^1\) into a box C \(^1\). The back of this box is free to slide in and out, and is connected to a lever s centred on a support t fixed to the main frame A; the pin which connects the lever s to the support t also connects to the same support a curved lever u. A bar v, which supports the vertical rods G G, presses in its downward motion upon rods G G, presses in its downward motion upon the curved portion of the lever u, and through the lever s causes the back of the box C  $^1$  to carry

forward into the box the envelope last delivered from the creasing box. The box  $C^{-1}$  extends to the front of the machine, and forms a table, which may be used by the attendant while banding the envelopes into packets as they are taken out of

The two fingers q q, for folding the end flaps of the envelope, as before explained, are arranged as shown in fig. 7, and act as follows:—They each consist of a plate with bevilled edges secured at back to a block x, and are furnished with adjusting back to a block x, and are furnished with adjusting screws. Each block x works upon a pivot y in an arm z, carrying a boss a formed with teeth on a portion of its periphery; the teeth on each boss are geared into by a rack or toothed boss on the upper part of a vertical rod  $c^1$ . The two vertical rods  $c^1$  are connected by a horizontal bar d 1 caused to rise and fall by another vertical bar  $a^{-1}$  caused to rise and fail by another vertical rod  $f^{-1}$ , the lower end of which is forked and furnished with a roller  $g^{-1}$  which rides over a cam 6 on the main shaft. In the down stroke of the forked vertical rod  $f^{-1}$  the racks on the rods  $c^{-1}$ , by gearing into the toothed bosses  $a^{-1}$ , causes the by gearing into the toothed bosses  $a^1$ , causes the fingers q q to turn upon their pivots y, and take up a position over the creasing box and under the top plunger, and so fold the flaps. In the up stroke of the rod  $f^1$  the fingers q q are caused to retire, and as soon as they are free from the plunger X a spring  $m^1$ , connected to the back of each finger block x, draws down the back of the block, and thereby raises the fore end of the finger.

The fingers  $q^1 q^2$  for folding the back and front flaps of the envelope are arranged and act similarly to the fingers  $q^q$ , for folding the end flaps, as just explained. The finger  $q^{-1}$  is acted on by a nearly vertical rod  $h^1$  toothed at its upper part and forked at bottom, where it carries a roller  $i^1$ , which rides even a roll of the financial of the folding that  $i^1$ . The which rides over a cam 7 on the main shaft. The finger  $q^2$  is similarly acted on by a rod  $j^1$ , roller  $l^1$ , and cam 8. In order that the top plunger X,

the second time it acts on each blank, may, after the fingers retire, exert greater pressure on the gummed portion of the envelope, ribs or projections n are formed on the face of the plunger, shown in fig. 8, which is a view of the face of the plunger to correspond with the gummed portion in addition to the ordinary rib or projection o 1 on the edges of the face of the plunger. As there are three thicknesses of paper at the gummed portion of the envelope, this portion consequently receives the greatest pressure. The plunger X is perforated for the escape of air. To prevent the envelope blanks adhering to each other, a portion of the supply plate A is removed, as seen at  $p^1$ , fig. 5, so that the lifters J J, in coming down upon the blanks, may press down and separate their edges.

The forked vertical rods referred to as being fitted with a roller riding on a cam on the main shaft are each furnished with a spring to keep the roller down upon the face of its cam. To raise the top plunger X and its beam Z when necessary for cleaning or repairing the machine a curved lever E is fitted on the main frame A. By turning the lever on its pivot it comes against a roller F 1 on the beam Z, and raises the beam until the roller falls into a slot formed for the purpose in the lever E 1.

The important economy of these machines is illustrated by the fact that over 200 of them are at present in operation in the United States, where they were originally brought out, and many others in England, France, and Germany. Two have recently been shipped to Egypt. Messrs. Waterrecently been supped to Egypt. Messrs. Water-low alone employ six of these machines, which give overy satisfaction. The mechanical arrange-ments are most perfect, and we believe this excellent apparatus only requires to be known to be generally used for envelope making by our leading manufacturing stationers.

### HORN'S SAFETY MINERS' LAMP.

LTHOUGH the Davy lamp, by its long use has become a recognized "institution" with miners, its acceptance and adoption are not to be taken as certificates of its perfect safety. It is not absolutely safe, but it has passed through the hands of several inventors who have tried to make it so. One of these, Mr. Story Horn, of 23, Grove-street, Newcastle-on-Tyne, has at last succeeded in perfecting it. So thoroughly has he done this that the entrance of the explosive gas within the lamp actually extinguishes it, as demonstrated to nary "Davy," an explosion is almost inevitable in a foul mine, if the lamp be moved suddenly or exposed to a strong draft. Its light also is feeble, by reason of the choking of the wire gauze with soot, whilst in Mr. Horn's lamp there is no such liability to choke, whilst the flame is bright and steady, brighter indeed when the lamp is closed than when it is open. Mr. Horn's lamp is—so to speak—a small furnace; the air entering below the fire, passing into an air chamber, and rising thence through holes pierced in a horizontal plate, to feed the flame. The products of combusplate, to feed the flame. The products of combus-tion escape through a narrow chimnoy and two perforated caps, which prevent down draught. If explosive gas enters with the air it has to pass through the holes in the horizontal plate, and as these are not close together, the gas burns as a feeble jet at each hole, instead of forming a body of flame, as it would if passed through the con-tiguous meshes of wire gauze. The accumulated smoke, resulting from the combustion of gas within the lamp, soon extinguishes both the jets, and the lamp itself, without explosion, as we have ourselves seen done with this lamp. This result ourselves seen done with this lamp. This result would simply leave the miner to grope his way to a place of safety from a point in the workings, where, with the ordinary "Davy," he and his comrades might have been blown to eternity without a warning.

The construction of Mr. Horn's safety lamp will be seen from the accompanying engravings, in which fig. 1 represents a side elevation and partial section of one form, whilst fig. 2 is a vertical section of a larger sized lamp, slightly varied from fig. 1. Fig. 3 is a sectional detail of the locking arrangement shown in fig. 1. In these figures, A is the oil reservoir and base of the lamp, provided with a tube B in the centre, for the reception of the wick or cotton, as shown in fig. 2, and for replenishing the reservoir with oil. C is the air chamber, screwed at a to the top of the oil reservoir. The top plate b of the air chamber is finely perforated, and its circumference is com- am enabled to bear my testimony to the value of posed of wire gauze c. D is the combustion your invention. The repeated experiments I made

chamber surrounding the wick, the top being formed by the removable metal dome E, central aperture for the passage of the wick. Α bayonet joint serves to connect the dome E with flange F, which has an annular dovetail groove d on its upper surface, for the reception of the lower edge of the glass chimney G, which is permanently cemented in it. A bead round the top and bottom of the glass chimney, in order to form a more secure hold for the cement. The flange F is screwed into the outer ring H, which forms the upper portion of the base of the lamp. This ring H is perforated circumferentially, as shown at ff (fig. 2), in order to admit air horizontally into the air chamber C.

With a view to protect the air chamber from any sudden gust, "blow," or outburst of gas or air, an outer perforated guard I of an annular form is applied round the perforations f f. This guard may either be made solid with the ring II, as shown in fig. 1, where a series of per-erations  $g g^{-1}$ , are shown both at the top and bottom, the perforations f being dispensed with, or it may be a separate loose attachment with perforations  $g^{-1}$  at the bottom only, as shown in fig. 2, n which latter case it is fixed in position by screws. The products of combustion pass up the glass chimney G, through the contracted aperture h in the metal cone K, which is fitted on to the top of the chimney. This cone is enclosed in a double cap of copper, the inner one L being perforated at the sides and top, whilst the outer one M is only perforated at the top. The cone and caps can be readily removed for the purposes of cleaning or repairs. The glass chimney is sometimes or repairs. The glass chimney is sometimes surrounded with a cylindrical wire gauze cage N, as shown in fig. 2, as a protection against breakage, but, if not found requisite, this protection may be dispensed with, as shown in fig. 1. When using the wire gauze, it is secured in place by nipping its lower edge between the ring or flange F and the part H, as shown in fig. 2, the various joints in the lamp being sufficiently tight to exclude all air excepting that which passes through the air chamber C, so that should the gauze N be taken out the lamp

will remain as safe as before. Mr. Horn's improved mode of locking the lamp is shown in fig. 1, and consists of two lamp is shown in fig. 1, and consists of two holes, which are respectively drilled in the top rim O and bottom flange, the last-mentioned hole being continued, as shown at i, into the metal of the base A of the lamp. P is a sliding steel rod, held upwards, when left free, by a belical spring k, the rod, when forced down, the rod is the reserved to the rod of the rod. entering like a bolt into the recess or spring i and thereby effectually preventing the base from being unscrewed. This rod is held down by the being thecrewed. This rod is not down by the hinged cover Q of the lamp (shown turned back in fig. 1), which presses upon the top of the rod P when closed, and keeps it in its locked position. The cover is locked when shut down in the by means of a concealed screw l (shown in the sentional detail for 3) having an oyal-shaped sectional detail, fig. 3) having an oval-shaped head which fits a correspondingly shaped key. This screw is contained within a piece of metal m fast on the cover, the piece of metal having a slit or opening formed in it for the entrance of a metal tongue n on the rim O. hole is made transversely through the tongue n, and when the parts are in their closed positions the screw l is turned by a key, so as to cause it to pass through the hole in the tongue, thus locking the cover down and maintaining the lower end of the rod P in the aperture in the base of the lamp. A small plate l 1 serves to prevent the entire withdrawal of the screw from the lamp, but so soon as the end of the screw is withdrawn from the tongue the spring k forces upwards the rod P, and leaves the base A free to be unscrewed or detached. A small pin p in the rod P prevents it from rising too high. The lock is placed at the base when a gauze protector is used, as shown in fig. 2, the concealed screw l having an oval-shaped head entering direct into a hole or recess in the side of the base. In this arrangement of lock the top or cover Q will be permanently fixed to the rim. It will thus be seen that Mr. Horn has succeeded in producing a lamp which is really entitled to the prefix of "safety." The value of this invention cannot be over estimated.

An important fact in connection with this lamp is that it has successfully stood the test at Hotton Colliery, where it has been tried with the lamp-Conterly, where it has been tried with the testing apparatus fitted up there. Mr. Wm. Chandler Roberts, F.C.S., F.G.S., &c., has given Mr. Horn the following certificate under date of the 5th instant:—"It is with much pleasure that I am enabled to bear my testimony to the value of with your lamp were perfectly successful, the flame being invariably extinguished when the lamp was introduced into explosive mixtures of coal gas and air."

ON THE METHODS EMPLOYED IN DE-TERMINING THE COMMERCIAL VALUE AND THE PURITY OF COAL GAS.

BY MR. F. W. HARTLEY.

T the last meeting of the Society of Engineers, held April 5, 1869, Mr. F. W. Bryant, prosident, in the chair, a highly practical paper was read on the above subject by Mr. Hartley, and of which the following is a full abstract:— The author commenced by observing that in most transactions a purchaser could, to a considerable extent, secure his own interests by the exercise judgment and discretion, but that in the case of gas it was impossible, by ordinary observation, to determine if it were of the quality it should be. Legislative enactments had, therefore, been made to protect the consumers. The gas compa-nies in each of the large towns, and in most of the smaller places, were bound to maintain their gas at a certain illuminating power and degree of purity, as certified by a public officer, who was to be provided with testing apparatus, and upon whose evidence the gas company concerned was, in the event of non-compliance with the conditions established, to be liable to penalties, recoverable before a magistrate. These enactments had been really effective in protecting the consumer, but, unfortunately, no precise instructions have laid down until a recent date as to the conditions to be observed in testing. The amplest specification was that the gas should be burned from a 15-hole argand with a 7-inch chimney at the rate of five cubic feet per hour; should not discolour a or ne cubic feet per nour; should not discolour a current of gas; and should not contain more than 20 grains of sulphur in any form per 100 cubic feet. In 1860, it was also enacted that Cannel gas should be burned when tested for illuminating power from a batwing or fishtail burner, the feet per hour consumption being still adhered to.

Burners nominally of the same size and description produce for a given consumption vastly different effects. No definite standard being fixed, discrepancies and disputes as to the quality of the gas were inevitable. No particular photometer was ever specified, but this omission has led to no evil, ewing to Bunsen's being generally employed. No method was detailed for determining the quantity of sulphur, of which the gas was not to contain more than 20 grains per 100 cubic feet. Efforts have been made to secure uniformity in the apparemains to be done. The conditions imposed as to freedom from ammonia and sulphur were very stringent, and were agreed to in the absence of sufficient knowledge. An Act regulating the supply for the City of London was passed last year, which authorized the Board of Trade to year, which authorized the positive appoint three gas referees, whose business it is to define from time to time the standard of purity determine the methods by which it define from time to time the standard of purity for gas, determine the methods by which it should be tested, and issue precise instructions for the guidance of the actual operators, who are called gas examiners. The referees appointed are J. S. Peirce, Esq., F. J. Evans, Esq., and R. H. Patterson, Esq. Their first instructions were issued in January last, and are hereinafter referred to.

The commercial value and purity of coal gas depends :-

 On its illuminating power.
 On its freedom, to a certain extent, from ammonia.

3. On its freedom from sulphuretted hydrogen.
4. On its freedom, to a certain extent, from sulphur in any form other than sulphuretted

hydrogen.

Illuminating Power.—It appears from documentary evidence that in the very early days of gas lighting the construction of burners was well considered, and the conditions necessary for the production of the best effect thoroughly under-stood, but in spite of the reiterated teachings of competent men, burners of erroneous construction have during many years been produced in great numbers. Forty-three years ago, Christison and Turner published a statement of their experi-ments, the conclusions deducible from which the author of this paper has summarized as follows:-

1 That up to a certain maximum consumption for each burner, the light increases in a much greater ratio than the consumption of gas. 2. That for each burner there is a certain size

Digitized by Google

of flame which is most economical-a corollary of the first proposition.

3. That in argand burners the size of the holes and their distance from each other is of the utmost importance. The holes should be so near to each other that the flame unites at its base. For gas sp. gr. 550 to 650, the holes should be 1-32nd inch diameter and about 12-100ths of an inch apart. For gas of a higher gravity, the holes should be 1-50th inch diameter.

4. That the size of the central aperture of an argand exercises an important influence on the amount of light yielded.

5. That the greatest amount of light is obtained when the flame becomes tinged with yellow and is

near to the point of smoking.

6. That the glass chimney should be propor tioned to the size of the burner and the consumption desired.

7. That consumers, generally, cannot burn the gas in such manner as to produce the best effect on account of the liability of the flames to smoke.

These propositions really comprise all that is known respecting the principles which should govern the construction of gas burners. The sixth proposition is impracticable of application. Narrow chimneys are apt to become partly fused and opaque, they are liable to frequent breakage, and flames enclosed in narrow chimneys are apt to smoke on the least disturbance.

Among the teachers on the subject of gas burners may be mentioned Clegg, Peckstone, Alex. Wright, Lewis Thompson, Dr. Letheby, and Henry Bannister. Alex. Wright stated that of burners equally suited for the gas, and consuming it at the same rate, the most advantageous is the argand, next the batwing, and then the fishtail. That the larger the quantity of gas properly consumed in a given time from a burner, the greater is the light given per cubic foot. That the best results arise with a well formed but flagging flame and the worst with an irregular, wire-drawn flame. Lewis Thompson said in 1851, every burner has (1st) a certain fixed amount of gas which it will consume to advantage; and (2nd) gives its maxi-mum effect where the flame is on the point of That the quantity of light is greatest with the argand and the intensity with the fishtail. Poor or common coal gas should issue more gently than rich or Cannel coal gas, and from burners with larger holes than those for the latter

The yellow-tinged flame, the flagging flame, and the gentle current, all mean the same thing, viz., low pressure; and MM. Dumas, Regnault, Andouin, and Berard, have established as a general law "that the greatest illuminating power is obtained with low pressures, and the maximum light with pressures equal to 079 to 12 of an inch head of water." They further state that batwing burners of the same diameter, burning the same quantity of gas, yield more light when the slits are wide—1-36th of an inch gave them the best results. The diameter of the burner should be proportioned to the desired rate of consumption but is less important than the width of slit. That single jot burners are very disadvantageous. That a fishtail is not much superior to two single jets, with holes of the same diameter, if the holes be very small. That the fishtail is generally inferior to the batwing. That argand burners, of almost the same appearance, may require to burn double the quantity of gas to give the same quantity of light, which is dependant upon, 1st, the width of the jet holes or slit; 2nd, on the number of holes; 3rd, on the actual and relative dimensions of the apertures by which air gains access to the interior and exterior parts of the flame; 4th, on the height of the chimney.

The first three conclusions accord with Christison and Turner. As to the fourth, an increase in the height increases the consumption for the same light. An 8-inch chimney as against a 10-inch one was 5 to 7 per cent, more advantageous. The foregoing conclusions relate to common gas; Cannel gas, as before stated, requires somewhat higher pressures. The investigations of Dumas and associates were so exhaustive, and they expressed their conclusions so definitely, that they are frequently credited with having established principles which they only, in fact, confirmed.

Down to the year 1860 each operator was at liberty to choose the burner he fancied best; and so difference existed in the burners employed, that the light evolved by five feet of gas of the same quality may have differed to the extent of 20 per cent. with different operators. In the above year Mr. Geo. Lowe presented to a Committee of the House of Lords an argand burner with a steatite top, which was accepted as a standard burner. No

description of this burner was given in the Act of A similar burner (No. 1 in the table below), made by Mr. Sugg, was exhibited. The table was reby Mr. Sugg, was exhibited. The table was re-ferred to as illustration of the difference in the light evolved by 12-candle gas burning at the rate of five feet per hour. No. 1 had a steatite and the rest iron tops.

#### ARGAND BURNERS.

	No. 1.	No. 2.	No. 3.	No. 4.

In respect to flat flame burners for Cannel gas, the Act of 1860 is also not specific. diameter, the width of slit or of the jet holes, and the pressure at which they were to burn the gas, should have been stated, and also whether the side or edge of the flame was to be presented to the photometer. In practice, the side is presented. A point of light would emit an equal number of rays in all directions, but flat flames emit rather more from the side than from the edge, owing, no doubt, to part of the flame being further from the object illuminated, and the want of perfect tran-sparency in artificial lights. Any of the batwings specified in the table might be used as complying with the Act of 1860, when testing Cannel gas, although they afford very different results.

5ft, of 20-candle gas				

The sperm candle is a very defective standard. It is difficult, if not impossible, to obtain candles of uniform quality both in respect to the sperm and It is rarely that a candle burns at so low the wick. a rate as 120 grains per hour, and hence a standard light is rarely obtained. It is usual, however, to reject candles which diverge more than about ten per cent. from the standard rate, for there are good reasons for believing that, under favourable conditions, the variation in the light given, as with gas, is greater proportionately than the variation in the rate of consumption. No reliable data has been established on this point. In France, the standard light is produced by the combustion of colza oil at the nominal rate of 42 grammes per hour, in a carcel lamp, under specified conditions. The author has made hundreds of experiments with the carcel lamp and colza oil, and, in his opinion, it forms a worse standard even than the candle.

Various schemes have been proposed for the production of a standard light, the most promising of which is due to Mr. Keats, who proposes to use a modified and specially constructed moderator lamp, under special conditions, burning sperm oil at the rate of about 750 grains per hour. He secures a very close approximation to regularity of consumption and of light, the value of which is equal to ten sperm candles. Details are published in the "Journal of Gas Lighting," of March 16, 1869. The lamp and balance for use with the same were exhibited in connection with a pho-

A photometer is an instrument which is based upon-first, the power which the eyes possess of judging of the equal illumination of different parts of the same object; and, second, on the laws which govern the diffusion of light. There are various kinds of photometers, but only two are now much used, viz., Foucault's and Bunsen's. The first is used in France (description given), the latter in England. With both photometers, the object to be illuminated is a semi-transparent screen. Bunsen's screen consists of a piece of white paper, 3½in. to 4in. diameter, impregnated with wax or sperm, with the exception of a spot in the centre. Such a screen is of unequal transin the centre. Such a screen is of unequal trans-lucency, and when its sides are unequally illu-minated, the centre spot will, on the side least illuminated, appear comparatively dark and opaque; but when both sides are equally illuminated, the centre spot will be almost invisible.

If a light be put successively in the centres of globes of 2ft., 4ft., and 6ft. diameter respectively, it will, in such case, illuminate the whole interior surface; but inasmuch as the superficies of globes are to each other as the squares of their radii, it follows that while the quantity of light thrown upon a given area, say, one square inch, would, with the 2ft. globe, be equal to one, it would, with the 4ft. globe, be equal to only 25, and, with the 6ft. globe, to 111 only. This is expressed

by the law, that lights which equally illuminate an object are to each other as the squares of their respective distances from the object. The screen, when placed between two lights, and equally illuminated, may be conceived to form part of the boundary of two globes, in the centre of each of which respectively one of the lights is situated.

The Bunsen photometer is made in various forms, and ranges in length from 50in. to 100in. between the lights. That exhibited is Dr. Letheby's form, and is, in the author's opinion, the best photometer extant. It, like most other Bunsen photometers, consists of a wood rod, about 4in. broad, set on edge. The rod is graduated into squares of distances, which represent the value of the stronger light in multiples and decimal parts of the value of the weather light. A saddle or slide fits upon and carries the screen at right angles to the rod. The peculiarities of this photometer are, that the screen is enclosed in a small box, which is open at the ends and in front, and which is provided with two reflectors, set at an and which is provided with two relieveds, set at an angle, so as to reflect the images of the two sides of the screen to the eyes. The lights are partly enclosed by blackened, upright, wood screens, which prevent to a great extent the diffusion of light into the operating room, cut off from the operator's eyes all rays, save those reflected from the screen, and when certain additional pre-cautions are taken, obviate the necessity for blackening the ceiling and walls of the apartment, which is necessary with many photometers. Besides the photometer, it is necessary to employ a balance to weigh the candle or candles, an accurate meter to measure the gas, a delicate governor to maintain regularity in the gas supply, a cock with micrometer for making minute adjustments in the gas supply, and, lastly, a well made clock, to measure time.

The balance is usually separate from the photometer, and the candles have to be removed, in order to be weighed. The author has combined the balance with the photometer, so that the candles may be weighed in situ. This is a great improvement, as it adds to convenience and accuracy. Mr. Keats, some time since, adopted a similar practice, but his arrangement differed from the author's. The meter is furnished with an index, which shows the hourly rate of consumption in one minute. The governor is a delicate automatic instrument, capable of maintaining a constant pressure of gas on its outlet, although the pressure on its inlet may be greatly increased. The micrometer cock is interposed between the governor and the burner. The minute clock indicates seconds, and, in some cases, strikes as well as indicates minutes.

The proceedings in an experiment are as fol-Several sperm candles are cut into halves, and the wicks of the lower halves exposed by cut-ting away a portion of the sperm. The wicks are The wicks are ting away a portion of the sperm. The wicks are all lighted, and the candles allowed to burn in a place free from draughts, until a well-formed wick is, in each case, attained. The candles are then all carefully extinguished, by touching the top of the wicks with a piece of sperm and immediately blowing out the flame. The candles are then ready for use. Those which burn irregularly, or appear of inferior quality, are rejected.

The gas is turned on to the burner and lighted,

and the consumption adjusted by means of the governor and micrometer cock to five cubic feet per hour, time being taken by the minute clock. The candles are next lighted with special precautions. To preserve the wick well formed, they are nearly counterpoised in the balance, and when the candles have consumed so much sperm as to become lighter in weight than the counterpoise, and the balance just turns, the time is taken second by the aid of the clock. A weight is placed in a candle-holder pan equal to the standard quan-tity of sperm due to the time it is intended to make observations; for ten minutes, the weight would be 40 grains for two candles. Then comes the actual photometric experiment, which consists in moving the saddle to a position on the rod, in which both the reflected images of the sides of the screen appear equally illuminated. A reference to the scale on the rod gives the illuminating value of the gas flame as compared with two candles. One such observation is made for each minute, and the mean taken as the observed value of the gas. A watchful eye is kept upon the balance during the ninth minute, and when it again turns the time is taken, as at first. The difference between the times is, of course, the time occupied in consuming 40 grains of sperm. Another method is to weigh the candles, then light them promptly at any observed minute, use them for the complete minutes, and then suddenly extinguish and reweigh; the difference is the number of grains burned in ten minutes.

If it be assumed that the photometer indicated the value of the gas flame 12.8 candles, and that the candles burned 40 grains in 580 secondstime due to such consumption being 600 seconds it would be assumed that the candles gave more than a standard light, and the value of the gas would be raised by direct proportion to 13:24 candles:—580:600::128:13:24. A similar correction is made if the candles exceed the due time, and in this case the observed value of the gas would be reduced. In the second system of weighing, if the candles burned 41.38 grains in ten minutes in-stead of forty, taking 12.8 as the observed value of the gas, as before, the correction would be made in terms of grains—40: 41:38::12:8:13:24. The terms of grains—40:41:38::12:8:13:24. The gas referees lay down a condition that no test of gas referees tay down a condition that no least of illuminating power is to be recorded in the City test-ings in which the candles vary more than five grains each per hour from the standard rate of 120 grains per hour. The author's experience leads him to doubt whether sperm candles can be regularly produced by any means which will comply with this requirement.

It has not been usual in testing gas on behalf of the public, or indeed generally, to correct the volume for temperature and barometric pressure, but the referees have directed such corrections to be made, and the volume of gas as measured by the meter is to be reduced to a standard volume at 60deg. Fahrenheit and 30in. barometer. Five cubic feet of gas at 56deg. and 30:5in. would at 60deg. and 30in. measure 5:125 cubic feet; its denwould be greatest at 56deg. and 30-5in.; and it would give more light than five feet at 60deg, and 30in. The value of the gas would be reduced from 13·24 to 12·91 candles for 5·125:5::13·24: 12.91

Tables are used for correction of volume, which are identical with those published by Mr. Alexander Wright for use with his specific gravity apparatus. In theory, the correction of volume is right, and the author thinks such correction should be made, but some persons may dispute whether this refinement is necessary in commercial testings. Sometimes the gas company, and sometimes the public, will be put at a disadvantage by it, and it may be said that the commercial value of gas is dependent upon the light it yields under existing circumstances, and not upon what it would give under theoretical conditions.

(To be concluded in our next.)

### METROPOLITAN DISTRICT RAILWAY.

ON Tuesday last, Colonel Yolland, of the Board of Trade, inspected another section of the Metropolitan District Railway, which has been completed, and will be opened for public traffic on Monday next. The new portion consists of a double junction, uniting the western portion a double junction, uniting the western portion of the inner circuit at Gloucester-road, Brompton, and at Kensington, High-street, with the West London Extension line at West Brompton, and at a point about midway between that station and the Addison-road station on the same line. The two junctions have each double lines of rails, and are together about 24 miles in length. The Metropolitan Western Extension line terminates at South Kensington station, where it runs into the Metropolitan District line, that continues the cir cuit from that station eastwards. From South Kensington station, the Metropolitan is duplicated by the District to the Gloucester-road station, at a little beyond which the junction line curves round to the left, and passing Earl's-court in a westerly direction, again curves round to the south, and forms a junction with the West London Extension at the West Brompton station. The northern junction commences at the double station on the inner circuit at Kensington, High-street, and passes for a short distance alongside of the circuit, then strikes off by a wide curve in a south-westerly direction, and joins the southern junction near Earl's-court, where the four lines run alongside of each other for about half a mile, at the end of which, the lines again fork, the northern junction curving round to the right, passing under the West London Extension, and forming a junction with that line to the south of the Hammersmith-road. The junction lines are constructed thoughout in the open, although in deep cutting, excepting only a rather long covered way in the diverging curve

the West London line is by gradients of 1 in 62. Several double bridges are carried over the lines, to carry, amongst others, the roads known as Cromwell-lane, Spicer's-road, Raspberry-lane, Earl's-court-road, and the Warwick-road, with occupation bridges communicating with the triangular pieces of land between the curves at the junctions at each end. The permanent way is of the same excellent character as that upon the inner circuit, the rails being steel, and 85lb. to the yard There are eight sets of points for the two double junctions in the straight run at Earl's-court. The interlocking point and signal apparatus at this place are on the patent of Mr. F. Brady, of the South-Eastern, supplied by Messrs. Vickers Sons and Co. The point and signal apparatus at the and Co. The point and signal apparatus at the West London junction end, are by Messrs. Saxby and Farmor. The works, which are of the best description throughout, were laid out by Mr. John Fowler, ongineer-in-chief to the Metropolitan, with Mr. T. Marr Johnson as joint engineer. Messrs. Kelk, Waring Brothers, and Lucas, have executed the works as contractors. A neat and commodious station has been erected at West Brompton, but for the present, the erection of the contemplated station near the Hammersmith-road contemplated station near the Hammersmith-road will be deferred.

#### THE TOWER SUBWAY.

MONGST the many great improvements now going on in London to relieve the overcrowded state of traffic, and for opening up new means of communication, the Tower Subway is one which deserves especial notice, as forming an easy and safe connection between the two densely-populated districts situated north and south of the Thames, between London Bridge and the Thames Tunnel. This work is now in course of construction under the bed of the river, from Tower-hill to Tooley-street, and consists of a tunnel less than to looky-street, and consists of a tunno loss that a quarter of a mile in length, access being gained to it by a shaft at each end. The depth of these shafts will be 52 feet and 60 feet respectively, in which it is proposed to have plumb lifts for the transit of passengers, parcels, &c., to and from the subway, through which an omnibus running on steel rails is propelled, both being worked by steam power. In driving the subway, which will be about 22 feet below the bed of the river, a wrought-iron shield will be employed overlapping the tunnel, provided with doors in the front, through which workmen can drive the heading, but which can be immediately closed on any appearance of water, and so render all water-tight; this shield will be propelled by powerful screws, and as it progresses, the tunnel segments will be inserted. The whole of the work is under the superintendence of Mr. Peter W. Barlow, jun., C.E., the engineer; the contractor being Mr. J. H. Greathead, under whose superintendence the shafts are now being sunk by Mr. Thomas Tilley, of 2, Bond-court, Walbrook London, the well-known artesian well engineer The castings for these shafts and the tunnel, which are all made in segmental rings firmly bolted together, as also the manufacture of the shield, are entrusted to the firm of Messrs. Bells, Good-man, and Co., of the Walker Engine Works and Foundry, Newcastle-upon-Tyne, and 25, Walbrook, London. The Tower Subway was commenced on the 16th of last February, and as the shaft for the Middlesex side is already sunk to the depth of 60 feet, and the remainder of the work well advanced, we are informed that it is expected to be opened to the public before the commencement of the year 1870.

### THE LONDON ASSOCIATION OF FOREMEN ENGINEERS.

THE members of this institution met on Saturday, the 3rd inst., in their new hall at the City Terminus Hotel, and the assemblage was much more Terminus Hotel, and the assemblage was much more numerous than at any previous monthly meeting. The chair and vice-chair were filled by Mr. Newton, of the Mint, and Mr. Keyto, respectively. The first business consisted in the election of Mr. James Douglass, Chief Engineer to the Trinity Board, and Mr. W. Munro, of Lambeth, as honorary members, and of Messrs. T. Hughes, J. F. Wolff, J. E. Reed, H. Noble, R. Wood, and J. Bates, as ordinary members; Messrs. W. Fothergill, and W. Price, were also put in nomination for membership in the ordinary class. ordinary class.

Mr. Newton then proceeded to deliver an address. He commenced by congratulating his fellow members upon the advancement—steady, and apparently cernear the South Kensington station, and the passage under the West London Extension. Excepting at this part of the new line, the gradients are practically level; the descent and ascent in passing under the ways so well adapted for their monthly gatherings. It was in 1855, when the society was in its infancy,

and when it was regarded with a considerable amount of jealousy and distrust by employers, that he (Mr. Newton) had joined its ranks, and he was thankful he had lived to witness its development to the present state, and the disappearance of every vestige of antagonism to it on the part of the master engineers of the kingdom. To the scientific Press of London much of the success of the Association was due. Through its medium the transactions of the society were made known to the engineering community at large, and its internal mechanism and its springs of action explained. The inner life of the institution, and its peculiar blending of scientific the institution, and its peculiar blending of scientific investigation with benevolent design, had thus been revealed, and its adaptability for technical and pracinvestigation with benevolent design, had thus been revealed, and its adaptability for technical and practical purposes demonstrated, until, at last, the principal employers of London were among the firmest friends of the Association. This, Mr. Newton said, was matter for extreme congratulation, but there was still work to be done. It seemed impossible for individuals trained, as foremen were, in the workshop, not to be geognizant of the value as well as the dignity of labour, and labour was still essential to the prosperity of that society. Their larque had tided over many shoals, and escaped many quicksands, but the sea of public life abounded in hidden as well as patent dangers, and it was necessary always to keep a good look-out, and that the crew should, one and all, be prepared to do their duty. Hitherto, some of the ship's company had merely lounged upon the deck, and contributed little towards bringing the vessel into harbour. He heped that the idle members of the past would become the active workers of the future, and then, humanly speaking, all must go well with that institution.

Mr. Newton adverted to the gratifying fact that Dr. Percy and Professor Tyndall had promised papers on future occasions, and that thus there would be a welding, as it were, of scientific deduction and practical knowledge in their proceedings. By co-operation of this kind all would be benefited intellectually, and the information gained at the meetings would be utilized in the factory, so as to be made advantageous to employers. In conclusion, the chairman appealed to honorary members to come

meetings would be unified in the factory, so as to be made advantageous to employers. In conclusion, the chairman appealed to honorary members to come forward and assist the society by reading papers, and by joining in discussions. They might enter that hall without any sacrifice of dignity, and their presence would be hailed with the greatest satis-

The foregoing is but a brief resume of the chairman's address, which was listened to throughout with close attention, and applauded at its close. Mr. Robt. B. Vinicombe, of the Royal Arsenal, Woolwich, followed with a paper on "Gunpowder Machinery." This was of a thoroughly practical nature, and the whole of the processes connected with the production of the death-dealing compound were admirably explained by the author. The paper was copiously illustrated with diagrams, and was altogether calculated to enrich the transactions of the institution. The proceedings of Saturday were protracted to a late hour; but Messrs. Keyte, Irvine, Humes, and others, took part in the brief discussion which followed Mr. Vinicombe's paper, and votes of thanks to that gentleman and Mr. Nowton concluded the meeting. The foregoing is but a brief resume of the chair-Newton concluded the meeting.

# LEWTHWAITE'S PATENT MAGNETIC STEEL SHARPENER

WE have just had brought under our notice a very WE have just had brought under our notice a very excellent and simple instrument for giving an immediate and highly finished edge to knives, razors, scissors, surgical and all other cutting instruments. This wonderful little sharpener is the invention of Mr. J. Lewthwaite, of 33, Museumstreet, Bloomsbury, who is well known as the inventor and patentee of the celebrated railway ticket printing machine which was exhibited by Messrs. Waterlow and Sons at the International Exhibition of 1862, and to which was awarded the prize medal. These machines have attained great popularity, being largely in use all over the world. The sharpener owes its very peculiar properties to the introduction of the magnetic steel sand of Taraniki into its composition. A trial of this remarkably efficient and cheap fastener, both upon knives and scissors, enables us to speak confidently of its merits. It can be carried about in the waist-coat pecket, although larger sizes are made for household purposes, and its price is so low as to bring it within the reach of even the schoolboy with his first knife.

# Correspondence.

THE NITRATE OF SODA PROCESS.\*
MR. BESSEMER'S PROCESS.\* PROCESS AND

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I was one, of not many persons, who, upon the first announcement of what is called "the Bessemer process," but which should, in strictness of fact and language, be rather called "the Martien

• Patent No. 2082, A.D. 1855.

process with the Bessemer vessel," predicted that that process would fail in doing what it professed to do, namely, eliminate the sulphur and the phosphorus from cast iron. I did not witness the feu d'artific. of Mr. Bessemer's original converting vessel, which seems to have dazzled so many of the profanum vul m., but I saw a faithful representation of it at the Polytechnic Institution, where we had, as announced in the bills, "the Bessemer process every night." I saw, also, the samples of iron produced by that process, which, had I needed it, confirmed my previous opinion. This opinion was based simply upon our long and ample experience of the failure of the old finery to discharge those impurities by blowing air downwards into the metal, and common sense told me that the chemical action of the air blast could not be changed by the change from a downward to an upward current, although it might burn more carbon and more fron in its course. At the same time, I always anticipated that Mr. Bessemer would succeed in producing a valuable metal from the purer kinds of cast iron.

Now, I own that my attention was first directed by the above failure (to eliminate sulphur and phosphorus) to this great metallurgical problem. I began by considering for what bases phosphoric acid, if it could be formed from the phosphorus in the metal, would have the greatest affinity, and I soon saw that seda was one, not to mention that soda would liquefy the scorie, and leave the iron cleaner than it would turn out from a more viscous cinder. All that I now wanted was nascent oxygen to form phosphoric acid, and nitric acid at once offered me this element; while the nitrate of soda containing it inis a substance most abundant in nature, and not sexcessive in price. This, of course, decided me at once to adopt it. But I wished to increase, if possible, the number of bases offered to the nascent phosphoric acid, and with it the chances of its formation. I recollected the contract of the chances of its formation. phosphoric acid, and with it the chances of its forma-tion. I recollected two facts favourable to this precaution—first, that "phosphate of alumina" had been found by analysis in iron scorie; and, second, that that most elegant of minerals "wavellite," is a native "phosphate of alumina." I, therefore, in-troduced a minute dose of kaolin, as affording that as probably leading to a "phosphate of lime," also a natural production. (I threw in nitrate of potash, though too dear for such a purpose, only to obviate though too dear for such a purpose, only to obviate any infringement under colour of employing it). any infringement under colour of employing it). These calculations and trials on the great scale having been completed. I solicited and obtained my patent, No. 1921, A.D. 1851, and I specified for the use of these several reagents in the puddling furnace, reserving my claim to the use of nitrate of soda, as a general purifier and converter of cast iron, for another patent which I subsequently obtained. My reason was this:—Martien had, in a most extra-ordinary specification, claimed the monopoly, by an abuse of general terms, of almost every salt known to chemistry, nay, of "any mineral or vegetable substance," and, thinking that I might give him a substance," and thinking that I might give him a peg on which to hang litigation, I disclaimed the use of any of my reagents in his "gutter process;" in short, I made him a present of whatever advantage he might contrive to extract from his generalities. Subsequent reading and reflection have taught me that I then had nothing to fear; that in patent law according to the process of agency let the spreads of the process of the strength term spreads. that I then had nothing to fear; that in patent law no one can, by the mere use of a general term, spread the net of a specification over the labours of future inventors, which, of late, it has been too much the fashion to attempt. To "specify" is the very opposite to "generalizing." The claims must be specifically made for what is in esse, not for what is in posse, and whether this can or cannot be comprehended under a general term makes no difference. We shall see some of our forestalling patentees come to grief upon this point before long, or I am much We shall see some of our forestalling patenties come to grief upon this point before long or I am much mistaken. In Betts v. Menzies, upon appeal to the House of Lords, the judges, in their answer to the lords said, "even if there were identity of language in the two specifications, if such identity consisted merely in terms of art, it would be impossible to predicate what meaning the first patentee attributed to such terms. . . . A mere barren general description, although it might contain an important suggestion, which a future inventor might avail him-self of, could not be considered as anticipatory of a future patent, although the terms describing the invention might be identical,—the one merely suggested the invention, while the other, by reducing the theory to practice, added to the amount of human knowledge, and conferred a benefit on mankind within the meaning of the patent laws." This language is conclusive, and I have quoted the words as a warning to patentees who put forth such pre-posterous claims as Mr. Martien's, to "all car-bonates, chlorides, nitrates, &c."

To return: I then obtained my second patent for the use of nitrate of soda as a purifier and converter of cast iron. I knew very well, from numerous trials, that to give my salt its full power as a reagent, it was necessary to imprison it, as it were, below the metallic bath, and so to counteract for a time its smaller specific gravity, and I was occupied in devising various adjustments for the purpose, when a cruel fraud to a large amount compelled me to abandon together my business and my patents. It will be seen, I trust, before long, how

far I had carried to perfection this important application, by methods which for years I have kept secret. In the meantime, I feel bound to yield the palm of priority to Mr. Heaton (he has done what I was then attempting to do), to whose inventive talent and merit I have given the highest testimony in my power, by joining the board of his company.

But I cannot conclude this communication without noticing the most extraordinary claim put forth by Mr. Bessemer, in his recent correspondence with Mr. Heaton, a claim not perhaps distinctly asserted but, at least, so suggested as to lead the unwary to take it for granted. He uses these words ("Times" money article. December 19, 1868):—" In the latter part of his letter, Mr. Heaton triumphantly points to the fact that I have taken out three patents for the use of nitrate of soda, and wishes, therefore, to infer that I approve his system. Now, Sir, the explanation of this point I should not have touched upon did I not feel that it was an imperative duty on my part not to conceal facts which so deeply affect the public interest; and that these facts may be clearly understood, I must go back to my patent of 1856, in which I declare my invention to consist in acting on a mass of melted crude or cast iron, when in a suitable vessel, by streams of oxygen (contained in atmospheric air or otherwise), and without the farther consumption of fuel for heating the vessel or into tseel or malleable iron. Now, whenever nitrate of soda is placed on the lower part of a suitable vessel and is covered by a perforated plate, the heat of the fluid pig iron, when poured on to the plate, will rapidly decompose the nitrate of soda, and 'streams of oxygen' will pass upwards, and (to use my own words) 'convert such crude or cast iron into steel or malleable iron, without the further consumption of fuel for heating the vessel or the iron.'"

Has Mr. Bessemer ever considered to what this construction of his specification must infallibly lead? Why, it leads simply and directly to his monepoly of almost every chemical substance known in nature. For, with the exception of not more than half a dozen, all occur as oxides or as saits of oxides, ready to give out these "streams of oxygen" when any future inventor shall have pointed out their use and importance! Difficult as it may be to perceive what "public" interest is involved in this claim, or what interest of any kind, save that of Mr. Bessemer himself, no one can doubt that by these words Mr. Bessemer intends to convey the notion that he had nitrate of soda within his purview when he specified in 1856. If he had, will any one believe that he, a man so keen in fencing round the so-called "Bessemer" process with the brambles of patent law, would have neglected to describe accurately and to define in unequivocal terms an application so important? Instead of this he is silent on the subject; he waits until another inventor has obtained two patents for the use of the nitrate salt, and not until these two patents have alpsed does he come forward and attempt to monopolize, by a nonessential mode of application, the use of that reagent. If he says that he had not this in view, then the case of Bette p. Menzies is directly in point and applicable to this covert and anticipatory language, and in any case he must give some proof in fact that such was part of the process actually employed by him in 1856. Now, I can state positively that at, or about, the time when I was engaged in drawing my own specifications, Mr. Bessemer was sending to my works ingot after ingot of his steel which would not stand the hammer, or "draw clear," and, as it seemed to me, was almost in despair at their failure. Such being the case, does Mr. Bessemer mean to suggest to the public that, at an epoch in his fortunes so very critical, he had the smallest idea of the power and efficiency of the nitrate of soda process? Either he had or h

And, now, having done with the language of his specification, and his suggested claim as arising upon it, I come to the operation itself, and, as a matter of science, deny most emphatically the existence of any "streams of oxygen" at all, arising from nitrate of soda, either submerged under molten iron, or blown into it. It is an entire misdescription, proceeding upon as entire a misconception of the real phenomena developed in the process. The reaction consists of

a series of detonations, or flashes, as of gunpowder, in which, at one and the same moment, or at successive moments quite undistinguishable in time, the mascent oxygen and the phosphorus unite, and the phosphoric acid so formed unites with the soda base, while the nascent nitrogen (which Mr. Bessemer has quite ignored) does its part as a steel-making element. Nay, more, if Mr. Bessemer did obtain his imagined "streams of oxygen" in a merely physical as contra-distinguished from a chemical condition, they would help him no more than his streams of common air to eliminate the phospherus and the sulphur, and, what is worse, they would leave behind them the most important element, the soda base, for the phosphoric acid to unite with at the instant of its formation. See Professor Miller's analysis of Heaton scoriae. The nitrate salt is the real steel-making agent in his operations; and let him be assured that, mask it as he will by blowing it in with air, no one pretending to the least knowledge of chemistry will fail to perceive that, while the air, in burning in part the carbon and the metal, evolves much of the requisite heat, it is the chemical reagent that does the work of purifying and converting the metal into steel. Let Mr. Bessemer try a current of pure oxygen gas (obtained from peroxide of manganeso or peroxide of barytes), and the failure will at once convince him of his error. Of this I have had the most complete and conclusive proofs in the production of some hundreds of tons of iron and puddled steel from the very worst and most impure cast iron both of England and of the Contineut, in bars which you might bend, but could not break; which you could twist, hot or cold, into any form without a flaw, and of which I retain some most striking samples. No air whatever was blown into or upon the metal so treated.

I have a further proof of the singular power and efficiency of this reagent in the fact that simply operating in the great ladle of the foundry in Her Majesty's Dockyard at Portsmouth, I produced castings which by trial gave a tenacity of from 12½ to 25 per cent. greater than the selfsame metal treated in the ordinary way. Where was the air blast in these decisive assays? Now, if we find that the air blast alone will not produce true steel, while nitrate of soda alone will produce it; and while nitrate of soda driven in by an air blast equally produces it, sound principles of induction mark that nitrate of soda is the really operative element. "What, then," it may be asked, "has Mr. Bessemer really himself dono?" I answer that he has done more than enough to establish a reputation. He took Mr. Martien's modification of the old finery in the blowing of air upwards through the metal instead of downwards, where it had to work at a disadvantage; and he invented a vessel in which this process could be practically applied to a pure metal. Finding that the blast did no more to eliminate the sulphur and phosphorus than the old finery blast, he wisely abandoned the insoluble problem and restricted his operations to cast iron free from those impurities. Baron Gruner says that what Mr. Bessemer produces is "not a true steel!" Be it so; but if Mr. Bessemer has not produced a true steel, still, if he has produced a new and highly useful and durable quality of iron, he has made a great step in metallurgy. But, ne suter ultra crepidam! Let him be contented with this, his own undisputed territory, and not seek to annex territories to which he cannot make a good and valid title.

There is another singular claim made by Mr. Bessemer, of which I should like to see some explanation, for I can hardly think that it is to be taken literally. He says (in the same letter to the "Times") "one of the conditions of my claim, however, is the retention of the malleable iron or steel in a fluid state, and the pouring of it while still fluid into ingot moulds." Now, what I want to know is this,—if I, by a process of my own invention, be it open to the public or not, wholly or in part, make malleable iron or steel in large quantities in a great ladle (and what is Mr. Bessemer's present vessel but a great ladle?) am I not at liberty to pour it into any mould that suits my purpose without a licence from him? From the grain of what I made in the foundry of Portsmouth Dockyard and elsewhere (and this was prior to Mr. Bessemer's pouretents) I should call it "steel," and it was all poured into various moulds again. When I have got my steel in the fluid state, can't I keep it so by means of heat suitably applied, without Mr. Bessemer's consent?

One more point and I have finished this critique. Mr. Bessemer says that he converts his cast iron without fuel." But is this so? He melts his cast iron: so does the old finery; and, of course, the same weight of metal requires the same weight of fuel. Now, Mr. Bessemer assumes that it is the superincumbent coke which heats the metallic bath in the finery. But, I say, and I can prove, that, after the metal is melted, this is not the fact. The finery cinder, which is thrown off in large quantities at the expense of the metal, just as in Mr. Bessemer's operation, is a silicate of the protoxide of iron. Whence comes this protoxide? Why, from the action of the air in the highly inclined blast which goes down into the very body of the metal, and, in

the oxidation of it, gives out the very heat obtained by Mr. Bessemer when he burns the same weight of metal! I have not the least doubt that we might metal! I have not the least doubt that we might remove the whole of the coke in the finery, as soon as the metal is melted, without any change in the results, which would bring us very near indeed to Mr. Bessemer's operation as now employed. Upon the whole, looking to these facts and phenomena, I cannot resist the conclusion that if Mr. Bessemer's I cannot resist the conclusion that, if Mr. Bessemer's present mode of blowing air downwards into melted cast iron (as I apprehend that mode) should become the subject of judicial enquiry, it will be held to be essentially the operation of the old finery. I abandoned my patent for a dipping tuyere which preceded Mr. Bessemer's on this very ground. I will only add that I have no longer any pecuniary interest in this matter (my patent having long ago lapsed) save that which I share with the general public, namely, that Mr. Bessemer should not be permitted, by raising a mist of non-essential adjustments and details around my nitrate of soda process, to re-erectit into a monopoly for his own private gains conclusion that, if Mr. Bessemer ments and details around my nutrate of sous process, to re-creetit into a monopoly for his own private gains at the public expense and mine.—I am, Sir, yours, &c.,

F. C. Knowles. Ryde, Isle of Wight, March 22.

### RAILWAY TRAIN COMMUNICATION.

RAILWAY TRAIN COMMUNICATION.

SIR,—I perceive by the public journals that "the rope system" of communication between passengers and guards is about to be adopted on all railway trains travelling more than twenty miles an hour. My impression has always been that this method, in the long run, would be found the cheapest, and most sure; and I think I was the first to advocate it, in a letter to your journal in or about the year 1840, under the signature of "Viator"; and I proposed also that the rope should run along under the eaves of the carriages, with openings in the pipe over the windows.

windows.

I should certainly then have tried the plan on one of the railways, but that in answer to my application to do so, the general manager of the Railway wrote me "it will never do to have every old woman pulling the string"; but I suppose, by this time, old women are more used to railway travelling, and general managers think they may be trusted.—I am, Sir, yours, &c. Andrew B. Brandram.

10, Eliot-place, Blackheath, S.E., April 3.

#### TO CORRESPONDENTS.

### Meetings for the Week.

Tues.—Royal Institution.—Professor Grant on "Astronomy," at 8 p.m.

The Institution of Civil Engineers.—Mr. T. N.
Kirkham, M. Inst. C.E., on "Experiment for the Standards of Comparison Employed for Testing the Illuminating Power of Coal Gas,"

at 8 p.m.

Testing the Huminature
at 8 p.m.
Who.—Royal United Service Institution.—Mr. George
Campbell, Bengal Civil Service, on "The
North-West Frontier of India," at 8.30 p.m.
Thurs.—Royal Institution.—Professor Tyndall on "Light,"
at 3 p.m.
Fal.—Royal Institution.—Mr. William Carruthers on
"Cryptogamic Forests," at 8 p.m.
Sar.—Boyal Institution.—Mr. A. Geikie on "Geology,"
at 8 p.m.

## Babal, Military, and Gunnery Items.

In order to prevent soldiers who have joined the reserve force enrolling themselves a second time by means of mutilated certificates of service, commanding officers have been requested not to issue more ing officers have been requested not to is than one certificate to a discharged soldier.

THE good service pensions of £150 a year each, vacant by the promotion of Captain W. K. Hall and Captain Thomas Wilson to the flag list, have been awarded to Captain Henry S. Hillyar, C.B., and Captain George Hancock.

THE Glasgow journals state that Messrs. J. and THE Glasgow journais state that messrs. J. and G. Thomson have received orders from Messrs. Burns and MacIver to construct two large screw steamers of upwards of 3,000 tons each for the Atlantic mail service. The new steamers are to be named the "Abyssinia" and the "Algeria."

IT is announced through the Atlantic Cable that It is announced through the Atlantic Cable that Sir Edward Cunard, Bart., died suddenly, from heart disease, in New York, on Tuesday evening. He was fifty-three years of age, and a principal partner in the house of Messrs. Cunard, Burns, and partner in the house of Messrs. MacIver, the steam ship owners.

An Admiralty order has been received for the An Admiraty order has been received for the closing of two of the three gates of Greenwich Hospital, at which visitors and the inmates have hitherto been admitted to the building. This is calculated to effect a saving of about £600 per annum, in reducing the number of metropolitan police employed from seventeen to seven.

THE Board of Trade have awarded a binocular The Board of Trade have awarded a dinocular glass to Captain Julius Martin Marcusson, of the Norwegian ship "Kongs Verre," for rescuing the master and crew of the barque "Viking," of Picton, Nova Scotia, on January 23, 1868, and conveying them to New York, having them for fifty-three days on board his ship.

SEVERAL instances have recently occurred in SAVERAL INSLANCES nave recently occurred in which officers on leave from regiments on foreign service, when required to perform duty in this country, or on the return voyage, have stated that they are without uniform; it has in consequence been directed in general orders just issued that officers are always to be in possession of their uniform; otherwise, if detailed for duty, they will be required to provide themselves with a fresh outfit.

An order has been issued from the Admiralty that all ships of war carrying twin-screw engines are to have their machinery fitted with Silver's steam governor. The largest vessel driven by twin screws in Her Majesty's navy at present in commission is the "Penelope," 3,096 tons, 600-horse power. The official reports from this vessel are highly favourable as regards the beneficial action of the steam governor at sea, especially in rough weather.

A GENERAL order, just issued, authorizes officers, non-commissioned officers, and soldiers who have received medals from the Royal Humane Society for acts of bravery in saving life to wear them on all occasions when in uniform. In all cases when an officer, non-commissioned officer, or soldier may be deemed worthy of receiving a second mark of distinction for saving life the Royal Humane Society have, with the concurrence of the Field-Marshal Commanding-in-Chief, agreed to add a clasp or bar to the medal already granted.

THE "Pall Mall" gives the following as an authentic anecdote of the late review at Dover:—
"When the 'Ferret' had, shortly after drifting against Dover Pier, become a complete wreck, signals were made from the shore to the Royal Sovereign, the flag-ship of the senior officer in command, informing him of the fact, as well as of the safety of the great with the expention of one boy. Costain the crew, with the exception of one boy. Captain Hood at once telegraphed the information to the Hood at once telegraphed the information to the Admiralty in London, and received in reply orders from that body to take the Royal Sovereign into Dover Harbour. Now, inasmuch as the entrance to the harbour is too narrow to admit the Royal Sovereign, and as, until after the half-tide, even the packet boats have often a difficulty in finding enough water to float them, the task was a difficult as well as a dangerous one to perform. Luckily, Captain Hood thought it best to act on his own responsibility."

This Board of Trade have awarded a gold watch to Captain J. De Waard, of the Dutch brig "Santa Rosa," in recognition of his services to the master and crew of the ship "Calumet," of Liverpool. The "Santa Rosa" fell in with the "Calumet" on November 16, 1868, in a sinking condition, in lat. 40.21 N. and long. 18.19 W., and received her master and crew, 32 in all, on board, landing them at Madeira on November 21. To effect this she was obliged, in consequence of the large number of persons on board, to deviate considerably from her course. The board have also awarded a telescope to Captain J. Lorange, of the Norwegian ship "Wilhelm Ludvig," for rescuing the crew of the bark "Enchantress," of Sunderland, in January, 1867. The "Wilhelm Ludvig," fell in with the "Enchantress" on January 10, about sixty miles S.W. of the Land's End, with her rudder broken, and in a sinking condition. She received the master and crew of the disabled vessel on board, and brought them in safety to St. Michael's Mountreads.

## Miscellanen.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending April 3, was 14,876. Total number since the opening of the Museum, free daily (May 12, 1858), 1,542,820.

AT the ordinary meeting of the Society of Engineers held on the 5th inst, Mr. F. W. Bryant, President, in the chair, a paper was read on the methods employed in the determination of the commercial value and purity of coal gas. by Mr. F. W. Hartley., weich we give in auother column.

Cop fish skin, heretofore considered quite worthless, and given away to any one who would take the trouble to haul it, is now, after having been ground fine, to be used as a fertiliser. This new kind of guano is said to be free from the disagreeable odour of the ordinary fish manure.

THE journals of Brunn, in Moravia, state that a Jewess, who lately attained the respectable age of 100 years, felt the other day a pain in her guns, which was soon after found to be caused by the appearance of four new teeth, which were forcing their wav down.

At the general monthly meeting of the Royal Institution of Great Britain, held Monday, April 5, 1869, Sir H. Holland, Bart., president, in the chair. Mr. Charles Chapman, Mrs. Cunliffe, Messrs. Walter Graham, Archibald Hamilton, and Henry Stone were elected members of the Royal Institution.

Eighteen Cornish engines were reported last month. These consumed 1,468 tons of coal, and lifted 11.7 million tons of water ten fathoms high. Average duty 53,700,000lb. lifted 1ft. high by the consumption of 112lb. of coal. Seven engines exceeded the average duty.

According to the official report of the harbour naster of Callso, the number of vessels which left that port during 1868, laden with guano from the Cincha Islands, amounted to 358. The quantity of guano which was exported during the year was estimated at 300,000 tons.

THE exports of coal from Belgium to France, in THE exports of coal from Belgium to France, in 1866, amounted to 3,226,378 tons, as compared with 3,014,452 tons, in 1867, and 3,393,649 tons in 1866. The quantity of coke exported from Belgium to France last year was 193,131 tons, as compared with 232,984 tons in 1867, and 292,793 tons in 1866.

At a meeting of the Board of Works last Friday it was determined that before sanctioning any scheme of tramways in the streets of the metropolis it would be desirable to have an experimental line between Westminster Bridge and Kennington Park, and the solicitor of the Board was directed to confer with the promoters of the bill before Parliament with a wing of making averagements for that approximation. view of making arrangements for that purpose

THE number of visitors to the South Kensington THE number of visitors to the South Kensington Museum during the week ending April 3, 1889, (Easter week free) was—on Monday, Tuesday, and Saturday from 10 a.m. to 10 p.m., 32,297; Meyrick and other galleries, 7,990; on Wednesday, Thursday, and Friday from 10 a.m. till 10 p.m., 10,757; Meyrick and other galleries, 3,310; total, 54,354. Average of corresponding week in former years, 25,747. Total from opening of Museum, 8,318,624.

In 1867 the total population of Cuba was 1,370,000 In 1867 the total population of Cuba was 1.370,000—of which 764,500 were whites and 605,550 were coloured. Of the coloured population 226,000 are designated as of the free class, but this includes, besides the freemen of negro blood, a large number of Chinese. More than three-fourths of the population, white and black, are in the western department, where the insurrection has as yet hardly made its appearance.

appearance.

INTELLIGENCE is to hand that a gold nugget weighing not less than 2001b. troy, has been found in Victoria. It is doubtful whether so large a quantity of the precious metal has ever been found before in one mass. The great nugget of 1858 weighed only 1461b. It is noticeable that all these great lumps of gold have been found in Australia. In 1730 a nugget, thought at that time to be immense, was turned up at Peru, but it weighed not more than 601b.

at Peru, but it weighed not more than 60lb.

ADDED to the changes in the Government departments at Woolwich, is the proposed abolition of the Royal Military Academy, which has held a high rank among the military educational establishments of the country. The school, it is stated, will be amalgamated with the Royal Military School, Sandhurst, and the building at Woolwich devoted to the purposes of advanced military instruction for the Royal Artillery. The Herbert Hospital at Shooter's-hill is to be given up, and the inmates housed in the Royal Marine Infirmary at Woolwich, which is at present unoccupied. For the future the Royal Marine Infirmary will be constituted a general hospital for regiments and corps of all branches of the service.

An interesting boatrace took place on Saturday after-

An interesting boat race took place on Saturday after-Aninteresting boatrace took place on Saturday afternoon between four homeless boys of Her Majesty's ship "Chichester," and four picked men from the Prussian man-of-war paddle steamer "Adler," at Greenhithe; the course was from the "Chichester" past the "Adler" and round the lower swinging buoy at Greenhithe, a distance of two miles, and back to the "Chichester." The lead was taken and kept throughout by the homeless boys. who, after a hard and "Chichester." The lead was taken and kept throughout by the homeless boys, who, after a hard and
exciting race, won by about six boats' lengths amid
the hearty cheers of their 200 messmates. The
race was watched with great interest and anxiety by
the officers and crew of the Prussian iron-clad frigate
"King William," moored at Greenhithe, who were
rather surprised at the result.

AT the meeting of the Institution of Civil Engineers, on Tuesday, the 6th inst., Mr. C. H. Gregory, President, in the Chair, ten candidates were balloted for, and declared to be duly elected, including one Member, viz.:—Mr. William Adams, Locomotive Superintendent of the North London Locomotive Superintendent of the North London Railway, Bow; and nine Associates, viz.:—Mr. W. F. Badgley, Mr. Arthur Carpmael, Mr. William Hackney, B. Sc., Mr. F. H. Hambleton, Mr. T. C. Hambling, Mr. B. Knorpp, Mr. W. F. Lawrence, Lieutenant R. A. Sargeaunt, R.E., and Mr. G. F. Verdon, C.B. It was also announced that the Council had admitted as Students of the Institution, Massers Happy Cartor, W. A. Dayron and J. H. R. Messrs. Henry Carter, W. A. Dawson, and J. H. R. King.

On Wednesday last, their Royal Highnesses, Princesses Louisa and Beatrice, attended by Lady Caroline Barrington, Mdlle. Bauer, Mdlle. Norelle, and Major-General Francis Seymour, C.B., honoured the Royal Polytechnic Institution with their presence, to hear Professor Pepper's lecture on and witness the experiments with the enormous induction coil by Mr. Apps. Their Royal Highnesses were received by the Chairman and Directors of the Royal Polytechnic Institution, at the private entrance, 5, Cavendish-square, and conducted to the royal box, which was fitted up in an elegant manner by Messrs. Druce and Videon. They retired evidently pleased with and Videon. They retired evidently pleased with the exertions of Professor Pepper and the Directors to entertain them on this occasion. We briefly described this great coil in our issue for the 25th ult. and propose next week to give a further account of both it and its mention. both it and its working.

At the meeting of the Royal Horticultural Society, held on Tuesday, the most prominent amongst flowers was the splendid show of roses from Mr. William Paul. Mr. C. Turner exhibited a very pretty Coleus, Princess Royal. A form of rhododendron Brookeanum was remarkable as a splendid specimen of cultivation. The collection of cucumbers which competed for the prizes offered was magnificent. Major R. Trevor Clarke presided, and the following candidates were elected fellows, viz.:—Henry Blaine, Mrs. Francis Coltman, Geo. Dixon, M.P., Henry J. Dixon, William Finnie, M.P., Francis Fuller, Alfred Gillett, Mrs. G. W. Lenox, Mrs. David Moore, Philip Saillard, Captain Gordon Shute, William Swinsoow, Henry Toogood, Charles Clement Tudway, &c. Messrs. Lane and Son's annual exhibition of spring flowers, now open in the arcades, will continue until the 17th inclusive, on which day the second spring show takes place. AT the meeting of the Royal Horticultural Society the second spring show takes place.

## Mutents for Inbentious.

### ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

ment:—
BOILERS AND FURNACES—2899, 2915, 2930, 2967
BUILDINGS AND BUILDING MATERIALS—2972
CHEMISTRY AND PHOTOGRAPHY—2931, 2959, 2970
CULTIVATION OF THE SOIL, including agricultural implements and machines,—2919, 2941, 2973
ELECTRICAL APPARATUS—2916, 2951
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2917, 2927, 2937, 2938, 2948, 2956, 2960, 2971, 2975
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2899, 2903, 2914, 2961, 2964
FURNITURE AND APPAREL, including beneabled attention.

2964
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—2896, 2307, 2908, 2910, 2922, 2924, 2925, 2926, 2994, 2943, 2948, 2949
GENRAL MACHINERY—2897, 2911, 2918, 2921, 2928, 2939, 2946, 2952, 2956, 2957, 2965, 2971
LIGHTING, HEATING, AND VENTILATING—2898, 2935, 2944, 2962

2962
MEFALS, including apparatus for their manufacture—
2950, 2963, 2968, 2994
MISCELLANEOUS—2901, 2902, 2904, 2906, 2929, 2932, 2933, 2940, 2945, 2946, 2956, 2957, 2958, 2961
BOADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2909, 2936, 2954, 2958, 2969

riages, 88 2958, 2969

SHIPS AND BOATS, including their fittings—2913, 2923 STEAM ENGINES—2911, 2983 WARFARE—2900, 2905, 2912, 2942

2895 N. JARVIE and W. MILLER, Glasgow. Manufacture of oakum, tow, &c. Dated September 19, 1868.

This consists in constructing and arranging the teasing apparatus, so that the portions of the fibrous substances will be firmly held and slowly fed forward, so as to be thoroughly acted up to the last, and so that no partially teased portions may pass through.—Patent abandoned.

2896 H. Fostes, Bermondsey. Graining and bruising leather. Dated September 19, 1868.
This consists in an endless band or belt, of a sufficient width, passing round two rollers or cylinders, mounted and revolving above a table, capable of being pressed up against

the band or belt by a treadle. One of the rollers or cylinders is mounted on an axis, carried in fixed bearings, and is driven with a slow motion, by suitable gearing, whilst the other roller or cylinder is mounted in bearings capable of adjustment, so as to keep the band or belt sluwsy distended, and revolves merely by friction with the band or belt which is driven by the first roller. That part of the band or belt which extends between the two cylinders immediately above the table, is supported above by a backing of wood, fixed to the side frames, so as to keep the band or belt perfectly flat, and prevent it from yielding to the pressure. The table which lies immediately beneath has its surface parallel to that of the backing, and is carried on a frame capable of rising and falling slightly in suitable guides.—Patent abandoned.

2897 G. SANDERS, Birmingham. Safety valves. (A com-

suitable guides.—Patent abandoned.

2897 G. SANDERS, Birmingham. Safety valves. (A communication.) Dated September 19, 1868.

This consists in the application of counteracting valves as a means for balancing safety valves. Compound valves are made use of, so arranged that one valve counteracts the other, the pressure upon each acting is contrary directions. The valves rise from their respective seats in consequence of the difference of these areas; also by the action of the escaping fluid upon an increased area of the larger valve overhanging the valve seating. The valves are weighted in order to counteract the different pressures upon them, consequent upon their different areas, by which means the required blow-off and pressures are regulated.—Patent completed. -Patent completed.

—Patent completed.

2898 J. H. JOHNSON, Lincoln's Inn. Lighting apparatus. (A communication). Dated September 19, 1868.

This relates to the construction of apparatus, whereby any number of gas jets may be ignited and extinguished simultaneously, and at any given hour, by self-acting mechanism; also to certain means for simultaneously lighting and extinguishing any desired number of gas jets, at the will of the attendant in charge of the gas main or mains. The first object is accomplished by the combined action of electricity and clockwork, whilst the second object is accomplished by the action of the pressure of gas, in overcoming, or being overcome, by the weight of a column of liquid which seals the mouth of the pipe through which the gas is supplied to the burner.—Patent completed.

2899 W. C. WOODCOCK, Owerton. Bakers' ovens. Dated

2899 W. C. WOODCOCK, Owerton. Bakers' ovens. Dated September 19, 1868.

The stove or furnace is constructed of firebrick or other refractory material set in masonry, of a square or other section, and of considerable height. This stove is provided with firebars, and a door for feeding the fuel, and an ashpit, on each side of which are air flues to admit coldair. The products of combustion and the consequent heat ascends through the rear and sides of the fireplace, communicating with the enlarged open space above, and after passing through two metal grated floors, to more equally distribute the heat, they reach the first floor of the oven (passing through the first, second, third, and fourth, or more floors contained therein), which is set on the upper part of the masonry, and enclosed on three sides and at the top, above which is the chimney, provided with a damper, standard, wheel, chain, and counterweight, to regulate the draught.—Patent completed.

2900 W. E. Lilley, Birmingham. Cartridges for breech-

regulate the draught.—Patent completed.

2900 W. E. LILLEY, Birmingham. Cartridges for breechloaders. Dated September 21, 1868.

This relates chiefly to the use of a rim-fire cap. A perforated metallic washer is inserted in the tube of the cap
on the top of the fulminate, pressure being afterwards
exorted thereon, so as to expand the washer, whereby the
closed end of the cap is enlarged. The cap is then inserted
through the aperture in a thin "base cup," the paper wad
is placed in the cup around the "rim-fire cap," and sufficient pressure employed to form the head. A second thin
"base cup" is then introduced above the paper wad, and
the turned over cartridge case placed therein. A second
paper wad is then inserted, and sufficient pressure used to
give a bevilled form to the front edge of the head.—Patent
abandoned.

abandoned.

2901 N. STEVENSON, Wimpole-street. Ornamental fountains. Dated September 21, 1868.

This consists of an open basin of crystal, carried by a hollow stem. Branches forming pipes lead from the stem to small subsidiary basins, and pipes starting from the bottom of the basins terminate in a well formed in the upper part of a closed reservoir, with the interior of which it communicates by a valve and air tube. There is a pipe running through the centre of the stem in its entire length, with its lower end entering the closed reservoir, and its upper end rising above the level of the basin. A union pipe of metal or elastic material is provided, by which the air tube is placed in communication with the pipe from a pneumatic pump or a reservoir of compressed air.—Patent completed.

completed.

2902 C. Wheeler, Speenhamland. Turning on or cutting off liquids. Dated September 21, 1868.

The patentee attaches by a flange or otherwise to the vessel containing the liquid, a bent tube or pipe; a second tube passes into a socket formed in the elbow tube, and the junction is effected by a rod or bolt passing through the two. To the second tube he attaches at right angles thereto a long tube, which must be the length of the depth of the vessel containing the liquid. The elbow tube is a fixture to the vessel, but the second tube with the long arm is free to turn therein. By depressing the latter, liquid is free to flow through the long tube, and by raising it, escape is cut off.—Patent completed.

2903 J. LORKIN, Norwood. Coffee and teapots, &c. Dated September 21, 1868.

This consists in constructing a channel, gutter, or water space around the outside of the upper portion of the coffee pot or other vessel, and in forming the lid with a depending rim, to enter or take into the channel or water space, the rim reaching nearly or quite to the bottom of the channel. The outer edge of the channel is preferably higher than the inner edge. When the channel or space is filled with cold water it not only forms a water lute or seal, to prevent the escape of steam, but also serves to condense the vapour, so that the liquid resulting from the condensation falls down into the pot, and the aroma is thus restored to the main contents of the pot.—Patent abandoned. abandoned.

2904 P. E. S. W. STOCKMANN, Keppel-street, W.C. Tents. Dated September 21, 1868.

The patentee employs instead of centre poles hollow rods or tubes of metal. Upon the lower ends of these rods

or tubes he forms screws, which he screws into suitable sockets. These sockets are formed on or connected to plates or flattened surfaces, having three or more arms or branches. These arms or branches are suitably bent downwards at their outward edges, to cause them to enter the ground to a slight extent. At or near the upper parts of the central tubular supports already described, arms or stretchers are pin jointed, or otherwise connected. These arms or stretchers are hellow, and serve to connect the central tubular supports with other tubular supports arranged on either side thereof, and when several of such side tubular supports are arranged side by side, they are connected to each other by connecting pieces, which extend from the one to the other, and these connecting pieces are also of tubular form. By these means the central tubular supports are held firmly together.—Patent completed.

2905 J. Kirk and J. Batstone, Westminster. Fixing

completed.

2905 J. KIRK and J. BATSTONE, Westminster. Fixing armour plates. Dated September 21, 1868.

This consists in attaching a lighter plate (say, about one-fourth the thickness), to the back of the armour plate, by means of eye bolts, and passing the shanks of the holding bolts through this back plate, the heads of the holding bolts being sunk into the back of the armour plate, and the shoulder of the bolt head abuting against the front of the back plate.—Patent completed.

the front of the back plate.—Patent completed.

2906 J. G. Piton, Cornhill. Bushing blocks and rollers.

Dated September 21, 1868.

This consists in constructing the sheaves of blocks and rollers with loose bushes, composed of one or more concentric rings of metal, or other suitable substance or material, a recess being formed in the sheave or roller, to receive the largest of such said rings, the other smaller rings fitting easily thereon and into each other, so that, when placed on the centre pin or axis of the sheave or roller, it moves thereon more freely than when the bush is fixed in the sheave or roller.—Patent completed.

2907 C. VERO. Atherstone. Hats. Dated September 21.

2907 C. VERO, Atherstone. Hats. Dated September 21,

2907 C. Verro, Atherstone. Hats. Dated September 21, 1868.

The first object is to produce a soft felt waterproof hat, having a fine outer surface and a coarser interior. The patentee produces in the usual way a soft felt hat of the coarser material, but thinner than usual, and he covers it with thin sheet guist-percha, or with a thin sheet of a composition softened by heat. Over the guita-percha he places a similar thin soft felt hat of finer material, and the whole is placed in a heated mould. By means of a hatter's hydraulic bag press, he presses the compound hat to the form of the mould, the heat of the mould softening the guita-percha, and causing it to stick the parts together. The inner hat or body may be made up of two or more thicknesses of felt. The second object is covering hat bodies of cork or of gossamer with felt or with woven fabrics. For this purpose, in place of causing the hat body and covering to adhere, by passing a heated from by hand in succession over every part of their surface, the body, with the covering is placed in a heated mould, and pressed together by a hatter's hydraulic bag press.—Patent completed.

2908 S. Fox, Deepcar. Umbrellas. Dated September 21,

2908 S. Fox, Deepcar. Umbrellas. Dated September 21,

1868. The object is to give to an umbrella or parasol, when open, a greater spread for a given length of rib, a greater stiffness to resist the action of the wind, and an improved droop or downward curve at the tips of the ribs. These objects are attained by giving to the ribs varying degrees of stiffness or elasticity throughout their length. For this purpose, strengthening pieces are applied to each rib, for a distance on each side of the "middle bit," which is fastened to the rib, and to which the end of the stretcher is jointed, or each rib may be thus strengthened for a distance on that side only of the middle bit which is towards its outer tip, the strengthening piece being applied to the rib close up to the middle bit.—Patent completed.

2909 F. W. Fox, Bristol. Locomotive engines and carriages

2909 F. W. Fox, Bristol. Locomotive engines and carriages

2909 F. W. Fox. Bristol. Locomotive engines and carriages Dated September 22, 1868.

The object is to dispense with the bogic trucks for railway engines and carriages. The patentee connects the contiguous ends of the framework of the engines or carriages or engine and carriages combined, by means of springs or elastic rings inserted in both or one of the frames, through which springs or elastic rings a circular bolt passes, securing the frames together in such a manner that they can freely turn laterally upon the bolt.—Patent abandoned.

abandoned.

2910 W. H. J. Grour, Commercial-road. Manufacture of tobacco pipes, &c. Dated September 22, 1868.

This consists of a table plate of equal thickness, and the required size, having projections thereon for the purpose of attaching a lever and screw of any desired length or diameter. Sides are screwed to the said table plate which have brackets of iron, steel, or brass, for supporting a horizontal spindle or shaft with a quadrant at each end; these have cogs or teeth thereon, and are made to gear into racks having cogs or teeth on one side. The racks are made to slide in grooves fixed to the said table plate, either in a vertical position or at an incline, to suit the action of the quadrants. A connecting rod is attached to the lever by means of a knuckle or circular joint, the other end of the connecting rod being connected to the quadrant spindle. The lever, being put in action, imparts a vertical motion to the screw, while the quadrant spindle receives a rotary motion at the same time.—Patent completed.

2911 W. L. Wise, Adelphi, W.C. Axie baxes, Dated

2911 W. L. Wise, Adelphi, W.C. Axle boxes. Dated eptember 22, 1868.

2911 W. L. Wise, Adelphi, W.C. Axie coxes. Dasen September 22, 1868.

This consists in a peculiar construction of axle box, in which the oil or other lubricant employed is contained in the lower part of the box itself, and is drawn up by capillary attraction through wicks to a saturated pad, which transfers it to, and ithus lubricates, the neck of the axle. The excess of oil or other lubricant, after passing on to the axle neck and falling therefrom, passes, on its return to the lower part of the box, through a filtering medium formed of canvas.—Patent abandoned.

2912 W. J. Murphy and J. B. O'Hea, Greenwich. Rifed barrets. Dated September 22, 1868.

This consists in the use of a punch or a mandril or core, having on its surface spiral projections or grooves, or both, according to the rifling desired, instead of a plain, cylindrical, or slightly conical punch, mandril, or core, wherewith to form the barrel.—Patent completed.

2913 C. E. BROOMAN, 166, Fleet-street, Registering speed vessels. (A communication). Dated September 22, 1868. This relates to registering the speed of vessels by pnear-

matic means, and consists in the employment, in combina-tion with a vane or screw, which is immersed in the water and dragged by the vessel, of an air chamber or vessel, which is alternately compressed and expanded by the revolutions of the vane or screw, and of a corresponding air chamber on board communicating by an airtight tube with the immersed air chamber.—Patent abandoned.

with the immersed air chamber.—Patent abandoned.

2914 B. C. Scott, Kingston. Measuring liquids. Dated
September 22, 1868.
This consists in so constructing measures as to dispense with the necessity of employing funnels. A spout
is affixed to the bottom and under side of the measure, a
hole being made through the bottom for that purpose;
into this hole a valve or plug fits watertight, and is connected to a vibrating lever adjusted to the top of the
measure at the handle.—Patent abandoned.

measure at the handle.—Patent abandoned.

2915 W. LEATHAM, Leeds. Preventing accidents to steam boilers. Dated September 22, 1868.

A chamber is mounted on the top of the boiler, which, near the bottom, is connected by two pipes with the interior of the boiler. These pipes are of different lengths; one of them opens into the boiler at such a level that its mouth becomes uncovered as soon as there is too little water in the boiler, while the other descends lower into the boiler. At the top of the chamber is an opening closed by avalve attached to a float within the chamber; when there is a proper quantity of water in the boiler, so that both the connecting pipes dip into the water in the boiler, the pressure steam forces water up the connecting pipes into the chamber and fills it until the float is raised so as to raise the valve. Directly, however, the water in the boiler sinks so as to leave uncovered the mouth of one of the connecting pipes, steam rises up this pipe, whilst the longer pipe acting as a syphon displaces the water from the chamber, and the float being no longer supported, falls, and so opens the valve, when steam immediately rushes through the opening, and is led by a pipe to a whistle, which it sounds.—Patent completed.

whistle, which it sounds.—Patent completed.

2916 R. Harling, Silvertown. Telegraphic instruments
Dated September 22, 1868.

This relates to improvements in telegraphic instruments on the Morse principle. Instead of the ordinary
style or pen, a rotating pen or marker is used, for printing
or embossing the paper. The pen consists of two concave
discs of steel or other metal, with tapered edges, placed
together so as to form a hollow chamber. These discs
are attached to the open end of a metal bar or thimble,
which serves as an ink reservoir. This box is made with
a hollow central stem to receive a screwed spindle, and a
clamping nut serves to retain the outer disc in place.—
Patent completed. Patent completed.

Patent completed.

2917 T. Lucas, Bury, and W. Grimshaw, Ashton.

Preparation of wool for letting. Dated September 23, 1868.

An ordinary carding engine is made use of, for the purpose of placing the fibres of the wool with their length in the same, or nearly the same, direction. As the wool leaves the doffer, it is received on a table, placed upon a reciprocating carriage, which traverses the desired length of a sheet, and when any required number of folds have been placed on the table, the doffer is stopped, and the wool passing from the doffer is cut to the desired length, and now lies on the table, which is moved on a pivot through any desired angle.—Patent abandoned.

2918 F. O. CALVERT, Manchester. Dyeing and printing Dated September 23, 1868.

This consists in the use of phosphoric acid, combined with various bases, such as lime, magnesia, and others, either with or without tanning substances, as mordants for dyeing and printing. The bleached or scoured yarns or fabrics are passed into a weak solution of one of the phosphates above described, previously dissolved in an acid, and then into a bath containing a vegetable, animal or coal tar dye.—Patent abandoned.

2919 E. H. PRENTICE, Stowmarket. Treating sewage
Dated September 23, 1868.
This consists in the addition of phosphoric acid, or
compounds thereof, known as superphosphates, or any
soluble salt of phosphoric acid, to the sewage matter or
other water to be acted upon, in the proportion of about
from 121b. to 151b. to 1,000 gallons of sewage, and in the
precipitation of such phosphoric acid or soluble phosphates,
by the addition of lime or any other earthy or alkaline
base, in the proportion of sowage.—Patent abandoned.

2920 J. MACKINTOSH and W. BOGGETT. Applying band.

2920 J. MACKINTOSH and W. BOGGETT. Applying bands to boots, &c. Dated September 23, 1868.

This relates to a patent, dated March 28, 1868, (No. 1065) and consists in the application of the same kind of fillets, thou described, to other parts of boots and shoes, as well as the fronts. A vertical cut is made down each side of the boot to the depth of about 5in., and four of five illets are introduced transversely across the opening between the leather and the lining.—Patent abandoned.

the leather and the lining.—Patent abandoned.

2921 E. W. HALLIDAY, Hammersmith. Lubricating machinery. Dated September 23, 1868.

A disc or plate, working between two fixed plates, is employed. A hole or holes are formed in the movable disc or plate, which alternately come opposite a hole or holes in one of the fixed plates, and then opposite a hole or holes in the other fixed plate; one of such fixed plates forms the bottom of the oil or grease cup, whilst the other is held in position by bolts and nuts, and is kept up to the movable plate or disc by means of a spring or springs or other means. The movable disc or plate is fixed to and operated by a rod or shaft, to which motion is given from any suitable part of the machine or engine.—Patent completed. 2922 H. LOMAX, Over Darwen. Sewing machines. Dated September 23, 1868. This consists in an increase.

September 23, 1868.
This consists in an improved construction of those parts of the sewing machine which press and move the material operated by means of what is usually termed a presser foot. A presser foot of novel and improved construction is employed, which consists of two parts, an outer frame, and an inner foot that presses and moves the material.—Patent completed.

2023 H. J. B. KENDALL, Great Winchester-street, E.C. reservative paint for ship's bottoms. Dated September 29

The composition consists of the following ingredients:

The composition consists of the following ingredients:

Arsenate of copper, exide of iron, carbonate of lime, crystallized strychnine, concentrated anhydrous extract of tobacco, crystallized borax. To these ingredients coal tar is added, and the whole is ground.—Patent abandoned.

2024 A. BARCLAY, Kilmarnock. Barometers and thermometers, and their combination with watches. Dated Sep-

2024 A. BARCLAY, Kilmarnock. Barometers and thermometers, and their combination with watches. Dated September 23, 1868.

The construction of barometer which it is preferred to employ consists of a thin hollow tube, of a section somewhat elliptical or flat. This tube is exhausted and fixed at one end to the case or framing of the instrument, whilst the other end is free and attached by a link to a lever, movable about a centre, and which at its opposite end carries a toothed rack, gearing into a pinlon, on the axis of which the indicating needle is fixed. The link is to be made of a more expansive metal than the tube, so as to counteract the expansion of the tube by heat. The barometer tube is placed in the case of the combined instrument so as to eneircle or surround the mechanism of the watch. The thermometer consists of a metallic tube, with or without a bulb at one end, filled with mercury or other liquid, which in its expansion or contraction causes the movement of alever, to which it is connected by a link in such a manner that the movements in the tube are communicated to it, and thence by means of a rack fixed at one end of the lever, which actuates a pinion carrying the indicating arm. The indicating arm is provided with a pencil, the point of which bears against a graduated sheet of paper, which is maintained travelling at an uniform and known rate, so that as the variations in temperature cause movements of the needle, the pencil point varies in position accordingly, and these variations are depicted upon the graduated travelling web or sheet of paper.—Patent completed.

2025 A. BOOTH and J. HARRISON, Stalybridge. Secing

paper.—Patent completed.

2925 A. Booth and J. Harrison, Stalybridge. Secing machine. Dated September 23, 1868.

This relates, first, to supplying the under thread in greater quantity than has hitherto been practicable, and consists in substituting a reel or bobbin, carrying the under thread in place of the shuttles or spools, such reel or bobbin being disposed in a cylindrical box or cavity, formed in the table or arm of the machine, parallel with the vertical needle bar, and placed upon a stationary circular at the bottom of the box or cavity. Second, to a novel feed motion, which is arranged to work in any direction, and consists of a sleeve surrounding a cylindrical bar, through which the needle bar reciprocates. Third, to a novel description of tension for the threads, which consists in applying the pressure of a three-legged spring to a seleve, upon which the bobbin is fixed.—Patent abandoned.

abandoned.

2926 J. H. GLEW, City-road. Button holes. Dated September 23, 1868.

This relates to a patent, dated January 10, 1868 (No. 93), and consists in inserting between the leathers or other substances of which the said boots shoes, gaiters, or other articles are constructed, pieces of vulcanized indiarubber, or other suitable material, having slits or holes therein, the slits or holes being placed over corresponding holes in the leathers. Both surfaces of the leather or other material, and also the india-rubber itself, may be conted with any suitable adhesive composition, so that the surfaces may adhere firmly one to another, or the two leathers may be also stitched together.—Patent completed.

pleted.

2927 C. Heptonstall, Kirkburton. Looms. Dated September 23, 1868.

This relates to the letting-off and taking-up motions or self-acting means of letting-off or delivering the warp, and of taking up or carrying forward the fabric as woven. A series of short beams or bobbins are employed, for holding and supplying the warp in sections; these are mounted in suitable framework, placed at the back of the loom in the usual manner. On each of these beams or bobbins a ratchet wheel is formed, to which is applied a catch lever hinged to the framework. The warp passes from these bobbins over one or more rails and the back beam, thence through the healds and the reed to the taking-up apparatus, in the usual manner, to each section of warp threads. Betwirt the rails a pendent tension weight of suitable size or weight, according to the amount of tension required, is suspended, or springs may be used. These weights are connected by cords or a chain to the catch levers so that as any one of the weights is raised by the taking-up motion, it lifts the catch lever out of the teeth of the ratchet wheel with which it is in connection, and thereby leaves the bobbin at liberty to turn on its axis, and let off warp: and as the weight lowers the catch lever, again takes into the ratchet and stops the rotation thereof, and consequently the let-off. The invention relates also to the taking-up motion in looms for weaving corsets, or other woven fabrics, and consists, first, in the application of worms and wheels, with a new combination of levers and ratchets for driving the grooved or fluted taking-up rollers. And, second, in the application of a toothed lever, to fit into and form a nip or hold on one of the fluted rollers, and tone an inpor hold on one of the fluted rollers, and thereby to employ only one series of such rollers instead of two series.—Patent completed.

such rollers instead of two series.—Patent completed.

2928 W. Thomas, Carnarvon. Circular saus. Dated September 23, 1868.

The saws are formed of a number of triangularly or other suitably-shaped segments, each segment forming a separate and independent tooth. These teeth or segments are retained or held between two circular discs or plates, in one of which a number of pins or dowels are securely fixed, two or more to each tooth; the pins projecting through the several teeth enter holes formed in the second disc. The two plates, with the segments between them, forming a saw, are placed upon an ordinary saw spindle, and screwed up firmly between washers.—Patent completed.

spinate, and screwed up irmiy between washers.—Patent completed.

2929 A. M. Weiri and M. A. Weiri, Bayswater. Previously Sympaling. Dated September 24, 1868.

This consists, first, in certain improvements in the valve boxes, valves, or taps employed for opening and closing communication between the tubes and compressing air vessel, or between them and the external atmosphere. Second, in employing in connection with the compressing instrument, a self-acting relief valve, for the purpose of maintaining the pressure of the air contained therein in equilibrium with that of the external atmosphere when signals are not being sent. Third, in an improved arrangement of the sending mechanism, whereby one movement of the handle or key is made to operate upon both the valve and air chamber at the same time. Fourth, in the arrangement and adaptation of mechanism, in connection with compressing or exhausting instruments, whereby the patentees are enabled to transmit motion to hammers or other instruments for ringing bells, discharging guns, exhibiting semaphore and other signals.—Patent completed.

2930 H. WOODS, Salford. Heating water. Dated Septem-

2930 H. Woods, Saltord. Heating water. Dated September 23, 1868.

The water to be heated is contained in a tank or cistern, made of wood or metal, or other material, and of sny suitable dimensions. The tank is fitted with one or more sets of steam chests or main pipes, which are thred in the interior of the said tank, and at a short distance above the bottom thereof, or are formed upon the bottom of the said tank, each of the said chests being connected to a corresponding chest by means of a number of bent tubes, each of which is attached by one end to one of the chests, and by the other end to the other end of the chests. The tubes penetrate into the body of water in the tank to a suitable distance in a vertical or other suitable direction, in order that the steam, when passing from one chest to the other, through the said tubes, may impart heat to the water. The steam eners one of the chests, and passes through the tubes to the other chest.—Patent completed.

2031 C. HENGST, H. COATSON, J. B. MUSCHAMP, and N.

chest.—Patent completed.

2931 C. HENGST, H. COATSON, J. B. MUSCHAMP, and N. WILSON, Holborn. Manufacture of carburetted hydrogen. Dated September 24, 1863.

This consisis in producing carburetted hydrogen or luminous gas, from the volatilization of hydrocarbonaceous fluids, known under the name of dead oils, gas tars, petroleum, vegetable tar, common fat, or oelic acid, in any form. In the process of volatilization, the hydrocarbona or dead oils are taken and placed in a receiver or tank, so as to obtain the necessary head or fall, to insure their flowing freely into the retort, and there combining with superheated steam. The heat of the superheated steam volatilizes the hydrocarbon in the retort, and it passes off through the exit pipe on its way to the gas holder. Intervening between the gasholder and the retort, is a condenser of any known form.—Patent completed.

denser of any known form.—Patent completed.

2932 W. Dunn, Newington-green. Substitute for the soldering of pipes. Dated September 24, 1868.

The object is to dispense with soldering in the connecting of cocks, unions, flanges, or Ts, to metal or other pipes. At the end of one pipe, a boss of any suitable metal, and of any desired shape applicable to the purpose, is affixed. This boss is provided on its exterior with a screw thread, and has under it a projecting nose at the fore end. A nut is then taken and tapped with a thread of the pipe to be connected, which is bulged.—Patent completed.

2933 E. Death and J. Ell.wood, Leicester. Pumping apparatus. Dated September 24, 1868.

A spur wheel fixed on the main vertical shaft is made

to gear with a pinion suitably mounted. On this pinion a flange or disc crank connected by a pin to the piston reds of the pumps is formed. The pin traverses in a slot link between and forms part of the two piston rods.—Patent abandoned. abandoned.

abandoned.

2934 E. DEATH and J. ELLWOOD, Leicester. Culting leather, Ac. Dated September 24, 1868.

Its object is the substitution of a continuously revolving roller, with knives or cutters on its periphery, for the ordinary vertical reciprocating apparatus, and consists in the use of a roller with a series of suitably formed knives or cutters, fixed on the periphery of the roller at the requisite distances apart. This roller is caused to revolve in contact with and press against another roller covered with wood, lead, or other suitable substance, that will not injure the cutting edges of the knives or cutters on the said knife rollers.—Patent completed.

2935 D. Cowan, Long-acre. Float values for cistors.

Dated September 24, 1868.

The float valve is constructed of two parts, a float which is an airtight vessel, circular in shape, with a domeshaped cover, and having a central opening up to the cover, large enough to pass over the valve, and a valve of an egg shape with a central spindle, upon which is a button or chack to close upon the valve seat. This button rests in a cup underneath, through which the spindle moves freely in a vertical position.—Patent abandoned.

2936 J. FRY, Marylebone. Wheels. Dated September 24,

1868. This object is to make a wheel, one of the spokes of which can be readily removed and replaced. A circular metal box and nave is cast in two parts with projecting lugs, placed at equal distances on the outer edge of their circumference; the lugs correspond in number with the spokes to be used in making the wheel.—Patent completed.

2937 C. Callow, Burnby. Looms. Dated September 24

1868.

This relates to improved mechanism for "letting off" the warp, as described in the specification of patent No. 2708, 1855. Near one or both ends of the vibrator a loose boss, having three arms thereon, is placed. To the outer arm a link and weight are attached, and to the inner arm is attached, by a screwed or chased rod and nob, a chain, which is passed round the neck of the warp beam to a stud fixed to the framing of the loom. The centre or third arm is operated upon by the upper rod of the vibrator,—Patent abandoned,

third arm is operated upon by the upper rod of the vibrator.—Patent abandoned,

2038 J. F. WARNER, Charles-street, W. Embroidering fabrics. Dated September 24, 1868.

First, there is a rotating bobbin holder, capable of containing an indefinite number of bobbins, and having in the centre a hollow tube or spindle for receiving the threads and geared in relation to the erothet hook or needle, in such a manner that the latter is encircled by the thread, which passes before it, during the movement of the bobbin holder. Second, a system of vertical rock levers, operated by cams, employed in distributing the threads which are to be applied in the form of a chain stitch to the fabric. Third, several crotchet hooks, and one, two, or more vertical thread guides, and a fixed bobbin holder. Fourth, a combination with the preceding mechanism of vertical rocking thread guides, for distributing thread or wool, so as to form the embroidery. Fifth, an arrangement of mechanism for connecting and disconnecting the vertical thread guides with the actuating mechanism. Sixth, a cam of special form, for operating the thread guides, which form a crossed point or stitch. Seventh, a large rotating table, on which may be piaced objects of considerable bulk, which may be manouvred with facility. Fighth, a substitution of hand power for pedal power by the treadle.—Patent completed.

2039 W. T. WATTS and D. F. Fleetwood. Hydraulic.

2989 W. T. WATTS and D. F. FLEETWOOD. Hydraulic. This refers to a patent, dated August 28, 1867. Upon a

main shaft are fixed cams, governing the forcer and like wise the pressure plate. The action of these cams is reciprocating, and by a ratchet motion or other mechanism, the forcer may be caused to advance any desired distance at each revolution of the cam shaft, whilst by the alternating force of the pressure plate cams are intermittent, and pulsative action is given to the pressure plate; or the same result is obtained by interposing hydraulic cylinders between the forcer and pressure plate cams, or either of them, and the die or mould, thus enabling the patentees to regulate, by means of suitable valves, the pressure generated by the action of the cams.—Patent completed.

2940 J. Boggs, Holborn. Making white lead. Dated Sep. tember 25, 1868

tempor 20, 1868.
Where cast blue lead is employed for making white lead, the patentee casts the metallic lead upon very hot plates, and makes the white lead in pots. In effecting corrosion, he uses nitric, nitrous, and acetic acids.—Patent abandoned.

2941 J. TORBITT, Belfast. Treatment of the potato. Dated

2941 J. TORBITT, Belfast. Treatment of the potato. Dated September 25, 1868.

This consists in digesting the washed tuber in water, at a temperature below the gelatinizing point of starch, but sufficiently elevated and continued for a sufficient length of time to soften and render flexible its fibrous structure, so as to permit of the separation of its liquid from its solid constituents, by mechanical pressure.—Patent completed.

constituents, by mechanical pressure.—Patent completed.

2942 C. E. Brooman, 166, Fleet-street. Breech-loaders.
(A communication.) Dated September 25, 1868.

This consists in closing the breech by means of a vertical sliding block worked by the trigger guard, which in the same movement cocks the gun, raises the sliding block, to allow of the insertion of a cartridge, and acts on an extractor. The sliding block has an opening at the lower part, while its upper part is solld, and carries the exploding pin. A transverse pin in the lower part of the block takes into a slot in a plate at the front end of the trigger guard. The guard is pivoted on the hammer pin, and a spring catch secures it when in place. The extractor is a vertical piece, pivoted near its centre, and its lower end has a tail-piece or back projection; a spring presses the tail back, and keeps the upper end or extractor proper in position. The tang has projections, to enter corresponding holes in the breech end of the barrel, and is recessed at the top to guide the cartridge.—Patent completed.

2943 J. L. R. Steckel, Ottawa, Canada. Musical instru-

2943 J. L. R. STECKEL, Ottawa, Canada. Musical instru-rments. Dated September 25, 1868.

This consists in substituting for the circular and com-paratively small holes or openings now in use in wind instruments, openings of an oblong form, and of much lurger area relatively to the size of the tube than is ordi-nary, and increasing gradually in size from the foot of the instrument to the embouchure.—Patent abandoned.

2944 J. WRIGHT and W. H. WILLIAMS, Birmingham.

Gas burners. Dated September 25, 1868.

This relates to fish-tail burners. Instead of forming them solid and drilled out on the interior, the patentees form them of a tube, cast or otherwise produced, and apply a metal tip within the top of the tube, in such a manner that the said tip may be removed for the purpose of renewal, when or as often as required.—Patent completed.

2945 P. KEAN, Glasgow. Dyeing. Dated September 25,

1868.

The dye stuff is placed in a tank or cistern, which is divided into any suitable number of water-tight compartments. The different dyes may be arranged separately in the compartments. The fabrics are carried upon a beam or roller placed at or near one end of the cistern or tank, and are led through the different compartments of the cistern in which the different dyes are placed, by means of sinking and press rollers.—Patent abandoned.

2946 C. SCRIVEN and W. HOLDSWORTH. Planing, boring,

2946 C. SCRIVEN and W. HOLDSWORTH. Planing, boring, and slotting. Dated September 25, 1868.

The tool holder traverses the cross slide by means of screws or other appliances; it is self-acting and adjustable to any length of stroke within the range of the machine. The body to be operated upon is fixed on the table or bed plate of the machine, which is self-acting, longitudinally, as an ordinary planing machine, and can be so used.—

Patent abandoned.

2947 W. E. Newton, Chancery-lane. Adhesive stamps.
(A communication.) Dated September 25, 1868.

This relates to a method of cancelling stamps. The stamps are made with a hole or holes through the body, and are covered or backed with tissue or other thin bibulous paper, coated with mucilage or other adhesive substance. On applying the mucilage, a certain portion of such backing is insulated within the area of the holes.

—Patent abandoned.

or such backing is insulated within the area of the holes.—Patent abandoned.

2948 G. RITCHIR, Hounslow. Sunproof fabrics and tents.
Dated September 25, 1868.

In the construction of waterproof and sunproof fabrics, the patentee takes two sheets of woven cotton or other fabric, and thoroughly cleanses and removes all grease from them, by sosking or boiling them in alkaline solution. The fabrics are afterwards thoroughly rinsed and dried, and cork dust, mixed with waterproof and elastic gum or india-rubber cement, is then spread upon one or both fabrics by a spreading machine. The coated surfaces of the fabrics are then placed together, and these two fabrics are passed between two rollers, by which the mingled cork dust and cement is squeezed, not only into the interstices of the fabrics, but also through the fabrics, to form an external coating to them. The fabrics being thus united inseparably together, and three interstices filled in with cork dust and cement, their outer surfaces are made flat and smooth by other rollers, and may then be painted, if required. By these means a fabric, suitable for being used as a covering for tents, is obtained.—Patent completed.

2949 W. J. LEDWARD, Middlesborough. Mechanical

2949 W. J. LEDWARD, Middlesson, mekkepers, Dated September 25, 1868. LEDWARD, Middlesborough. Mechanical

timekrepers.

timekeepers. Dated September 25, 1868.

The object is to record the time when workmen come to work. A till is employed to receive the tailies of the workmen. These tailies are dropped through the slit or mouth of the till into a series of drawers or boxes ranged vertically one above the other. Each of the drawers or boxes, with the exception of the lowest one, is carried on slidees or guides so that it can be instantaneously slid forward, and so brought under the end of the mouth or shoot of the till. The upper drawers or boxes are all first drawn

back and retained from covering over the lowest box of drawer, and any tallies dropped through the slit or mout of the till drop into the lowest box.—Patent abandoned.

THE

of the till drop into the lowest box.—Patent abandoned.

2950 R. ACLAND and J. HOCKING, Plymouth. Calcining ores. Dated September 25, 1863.

This consists in calcining ores, such as tin and copper, containing sulphur, arsenic, or other foreign substances, by exposing them to heat in contact with heated air by passing through a revolving tube or cylinder kept in constant steady motion, regulated in speed so as to keep them under the influence of heat a greater or less length of time, varying according to the constitution of the ores. The tube is constructed of either wrought or east iron lined with firebrick about 30ft. long, and 4ft. in diameter. On the exterior of the tube are three or more cast iron rings, which work on friction rollers, by which the tube is supported. The rotary motion is imparted by an endless screw working into a cogged ring. The ore is supplied in a regular steady stream at the end farthest from the fire, and by the revolving of the tube, which is elevated at one end.—Patent completed.

2951 E. Prevost, Notting-hill. Electro-magnets. Dated

2951 E. PREVOST, Notting-hill. Electro-magnets. Dated

2951 E. Prevost, Notting-hill, Electro-magnets, Dated September 25, 1868.

A bar of iron of the best quality is forged into a horse-shoe form, and immersed in a bath of molten lead, and allowed to cool slowly. This operation is repeated seven times; during the last, flowers of sulphur are added. The bar is then plunged in a bath of alcohol, at a high temperature, until the metal assumes a yollowish green colour, when sal ammoniac is added. When cooled, the bars possess great electrical power.—Pstent abandoned.

2952 P. J. E. CARON, Paris, Provining the breaking of

possess great electrical power.—Patent abandoned.
2952 P. J. E. Caron, Paris. Preenting the breakage of ropes in hoisting gear. Dated September 26, 1868.
This consists of a pulley turning on an axis in a casticno block, to which are connected the various parts of the machine. The block is provided with two arms, rising on each side of the pulley, and connected at their upper part. These arms form an integral part of the block, and may be cast therewith; they are further provided with lugs, carrying the small axes of the jaws. The jaws are moulded on the outside to the form of the chain, and are provided, at their lower parts with hooks to which are attached springs, whose outer ends are connected to the blocks at the lower parts of arms. Lovers of peculiar form are fixed to the upper part of the movable jaws, which levers are provided with friction rollers at their forked ends embracing the chain.—Patent completed.
2953 H. Daver, Victoria Chambers. Steam engines and

2953 H. DAVRY, Victoria Chambers. Steam engines and

2953 H. DAVEY, Victoria Chambers. Steam engines and pumps. Dated September 26, 1868.
This consists, first, in an improved means by which the admission and emission valves of steam engines are actuated so that the governor is made to vary the points in the stroke of the engine at which the supply steam is cut off with the varying resistances which the engine has to overcome. Second, in an improved means by which the piston of direct-acting steam engines is controlled, so that the engine is made to work smoothly, and is particularly applicable to steam pumps. Third, in means by which steam valves of direct-acting pumping engines are actuated.—Patent completed.

steam valves of direct-acting pumping engines are actuated.—Patent completed.

2954 J. H. JOHNSON, Lincoln's Inn. Permanent way.
(A communication.) Dated September 26, 1868.

This relates, first, to a method of securing the ordinary double-headed rails in chairs, whereby the usual wooden key is dispensed with. And, second, to a mode of constructing an iron permanent way which shall be as nearly as possible uniformly elastic. The chair may be secured in any convenient manner on to a wooden or other sleeper. An iron or steel wedge, which may be curved or bent, is driven underneath and at right angles or transversely to the rail, suitable openings being made in the lower part of the jaws of the chair for the purpose. By this means the rail is forced upwards, and jaumed tightly against a filling-piece which is inserted between one side of the rail and the jaw of the chair. In the second part of the invention, the chairs may hold the rails either in the ordinary manner, or they may be shaped and made so as to hold the rails in the manner first described.—Patent completed.

2955 J. SUTCLIFFE, Levenshulme. Warping mills and

2955 J. SUTCLIFFE, Levenshulme. Warping mills and

2955 J. SUTCLIFFR, Levenshulme. Warping mills and hecks. Dated September 26, 1863.

The object is, in the first place, to make the warping heck last double or treble or any number of times longer than hecks as hitherto made. Instead of putting only one hole on each shank, as hitherto, the patentee puts two, three, or any number of holes for the eyes on one shank, so that, when one hole is cut, the warpier can use another, and so on, until he has used all the holes. The object is, second, to make the warping hecks cheaper. Instead of brass racks and forged eyes, the patentee makes the hecks of flat rods of steel or fron by laying two rods of flat iron or steel side by side instead of the brass racks, and riveting or screwing short pieces of flat iron or steel to them, and putting two, three, or any number of holes in the flat iron or steel to form the eyes. The improvements in warping mills consist in arranging the driving shaft along the top or bottom of the mill at right angles to the mill, and using either wheels or friction pulleys for driving the mill. By this arrangement, the mill has not so many wearing parts, and, consequently, less oll will be used.—Patent completed.

2956 J. Rambottom, Crewe. Communicating in railway

Patent completed.

2956 J. RAMBOTTOM, Crewe. Communicating in railway trains. Dated September 26, 1868.

A slender cord is kept in a state of tension, and extending from the engine or tender at the front of the train along the sides of the carriages to the guard's van at the rear. This cord is supported in brackets fixed to the carriages at an uniform height and lateral distance from the rail, thus allowing the use of open loops to support the cord which is placed in any convenient position within reach of the passengers, but, by preference, a little below the windows or right hand side of the train. One end of the cord is attached to a gong, whistle, or other alarum at the front of the train, and the other end may be attached to a grooved pulley or reel in the guard's van attached to an alarum.—Patent abandoned.

2957 J. HEAL, Ashter-under-Lyne. System of gearing.

2957 J. HEAP, Ashtor-under-Lyne. System of gearing.

29.77 J. Heap. Ashtor-under-Lyne. System of gearing. Dated September 26, 1868.

This is applicable to lathes and also to other machines. The wheel or drum or speed pulley is made hollow, and runs loose on the shaft spindle or axis to which the slow motion is to be communicated. In the interior of this wheel drum or speed pulley is placed an internal toothed spur wheel, which is keyed on to the shaft spindle or axis to which the slow motion is to be communicated. Into this internal toothed spur wheel is geared an exterior

toothed spur wheel, which last has one, two, or more teeth less in its circumference than the internal toothed spur wheel.—Patent abandoned.

wheel.—Patent abandoned.

2958 C. F. Whitworth, G. Pearson, and W. Smith, Manchester. Safety apparatus for railroad inclines. Dated September 26, 1868.

Two main levers are employed parallel to one of the rails, and nearly close to it, so that the flanges of the wheels of the waggons or carriages can act upon them, the normal position of each lever being such as to present an upper surface inclined from near the bottom of the rail under which its axis is fixed to the top of the rail, near the level of which it terminates with a short curve downwards.—Patent abandoned. Patent abandoned.

of which it terminates with a short curve downwards.—Patent abandoned.

2959 P. Spence Manchester. Manufacture of copperus. Dated September 28, 1868.

Iron ores, containing a large amount of protoxide of iron are taken, preferably containing not less than 25 to 30 per cent. of iron, in the state of protoxide. These ores and slags are ground to powder, and the powder is line enough when passed through a sieve of twenty meshes to the lineal inch. Say, 2001b. of this powder are now taken, and having ascertained its proportion of iron in the state of protoxide, the quantity of acid required to combine with all the iron contained is calculated. The powder is put into a shallow basin in the floor of the house, and when the acid to be used is sulphuric acid of the ordinary chamber strength, then, before adding the acid, an ordinary bucket full of water is mixed with the powder in the basin. If the ore contains from 50 to 55 per cent. of iron in the state of protoxide, an equal weight of the acid is now added. In a few minutes, the mixture heats and becomes semi-liquid, then boils, and almost instantly becomes a pasty mass. It is then thrown out, and when cool becomes perfectly dry.—Patent completed.

and when cool becomes perfectly dry.—Patent completed. 2960 J. Petrie, jun., Rochdale. Washing wool, &c Dated September 26, 1868.

This relates, first, to those racks of washing machines which are caused to move to and fro in the fluid, while they vibrate upon a centre of motion, which are commonly called swing rakes, and consists in an arrangement whereby they become balanced. Second, to a method of mounting the rakes by the use of a parallel motion. Third, in a method of effecting a variation in the sweep of swing rakes. Fourth, in a method of delivering the material to the squeezing roller. And, fifth, to a method of constructing chains for travelling surfaces used in washing machines.—Patent completed.

#### APPLICATIONS FOR LETTERS PATENT

Dated March 30, 1869.

Dated March 30, 1869.

946 G. T. Bousfield, Loughborough Park, Brixton,
Surrey. Improvements in sewing machines.

947 C. Weckes, Great George-street, Westminster.
Improvements in the combustion of wood and other fuel,
particularly applicable to firewood.

948 J. Bath, King William-street, City. Improvements
in the construction of sliding or telescopic pencil cases,
adanted also for pens.

in the construction of sliding or telescopic pencil cases, adapted also for pens.

949 H. G. Dixon, Murraygate, Dundee. Improvements in the breaks and seats of velocipedes and apparatus connected therewith.

950 W. W. Harris, St. John's Wood. Improvements in velocipedes.

951 A. Muir, Victoria Bridge Works, Manchester. Improvements in velocipedes.

951 A. Muir, victoria brings works, manuscreat. Improvements in velocipedes.

952 M. M·Leod, Edinburgh. Improvements in railways, and in the mode of working the same.

953 C. E. Brooman, Flect-street, City, patent agent. Improved means of balling or winding threads, and apparatus employed therein, the apparatus being applicable to other purposes.

954 A. Barclay, Kilmarnock, Ayrshire. Improvements in the believe of generators.

954 A. Barclay, Kilmarnock, Ayrshire. Improvements in steam bollers or generators.
955-J. Briggs and J. Almond, Blackburn. Improvements in looms for weaving.
956 T. E. Williams, Newport, Monmouthshire. An improved method of, and apparatus for, distilling hydrocarbon oils.
957 W. F. Prototr, Cheapside, City. An improved construction of sewing machine table.
958 F. Render, Manchester. Improvements in railways.
959 T. G. Webb, Manchester. Improvements in furnaces for the manufacture of glass, commonly called melting furnaces, and in the manufacture of melting pots for the same.

metting turnaces, and L. for the same.

960 H. Y. D. Scott, Ealing, Middlesex. Improvements in lime and other kilns.

961 W. E. Cadman, Holloway, Middlesex. Improvements in decorating surfaces.

Dated March 31, 1869.

962 A. Chambers, Fairfield-road, Bow, Middlesex. Improvements in carriages, vehicles, or conveyances propelled or moved by manual power, parts of which improvements are applicable also to other purposes.

963 B. Dobson and J. Eastham, Bolton. Certain improvements in carding engines.

964 F. W. Follows and J. Bate, Manchester. Certain improvements in lawn mowing machines.

965 T. A. Dillon, Dublin. Improved methods of, and apparatus for, utilizing the waste steam of locomotive engines.

engines.
966 T. Greenwood, Leeds, and J. Keats, Leek, Stafford-

966 T. Greenwood, Leeds, and J. Nears, Lees, Commonshire. Improvements in the manufacture of boots and shoes, and in machinery to be used in such manufacture.

967 A. F. Reird, Pimico. Improvements in earth closets and urinals.

968 R. Johnson, Waterloo-place, Pall Mall. Improvements in the construction of continuous bar or strained wire fonces.

ments in the construction of continuous bar or strained wire fences.

969 G. Wells, Westminster. Improvements in separating copper and bismuth from ores containing metals, either separately or combined with other metals.

970 J. H. Lloyd, Llangetin, Anglesey, North Wales. Improved machinery for working, cutting, shaping, sawing, and hammering tools by power, and for apparatus connected therewith.

971 H. Davey, John-street, Adelphl, Middlesex. Improvements in hydraulic machinery, and in means of actuating ithe same, part of which is applicable to steam engines.

972 W. Langer, Whitechapel-road, Middlesex. A new and improved method of, and apparatus or appliances for, the manufacture of cigars.
973 R. J. B. Mills, Southampton-buildings, Middlesex. Improvements in envelopes.
974 T. Corbett, Shrewsbury, Salop. Improvements in carts, waggons, and drays.
975 B, and H. Craven, Hazlehead, near Sheffield, and J. N. Craven, Highthorne House, near York. An improved brick and tile pressing machine.
976 J. Livesey, Victoria Ckambers, Westminster. Improvements in the permanent way of railways.
977 J. A. and J. Hopkinson, Huddersfield. Improvements in direct-acting steam engine indicators.
978 R. Jones, Botolph-lane, City. Improvements in the preservation of animal and vegetable substances to be used as food.

preservation and assessment as food.

979 W. E. Gedge, Wellington-street, Strand. A novel method of fastening belts or bands by means of buckles termed belt buckles, with shifting wedges.

980 J. B. Gridley, Ingram-court, Fenchurch-street, City.

980 J. D. Grundy, angular of the control of the con Improve

ments in engraving and chasing articles of metal.

Dated April 1, 1869.

982 J. C. Lee, Ashton-on-Mersey, Chester. Certain methods of collecting exercts and the products of combustion ordinarily emitted by chimneys, and of treating the same in order to render them comparatively innocuous, and to obtain useful products therefrom.

983 C. Lange, Strand. Improvements relating to the winding mechanism of watches and clocks.

984 H. Carter and G. H. Edwards, Bow, M ddlesex. Improvements in a breech-loading firearms known as Chassepot rifles.

985 G. Holcroft and W. N. Dack, Manchester. Improvements in, and applicable to, steam engines.

986 J. Beckett and A. W. Field, Llandudno, Carnarvonshire. An improved self-acting brake for railway carriages.

riages. 87 E. O'Connell, Greenwich, Kent. Improvements in paratus for supplying nourishment to infants, invalids,

and others.

988 J. B. Bowcliffe, Manchester. Improvements in the
manufacture of wire cloth for paper making machines.

989 C. D. Norton, Old Street-road, E.C. A new and
improved method of making revolving boot and shoe heels
and tips.

990 T. Higgins, Warrington-gardens, Maida-hill, Middleare Improvements in hets.

990 T. Higgins, warringon-gauce, and a sex. Improvements in lats.
991 J. Caplin, Pentonville-road, Middlesex. Improvements in certain parts of umbrellas and parasols.
992 W. Gibson, Birmingham. Improvements in cramp keys or implements for taking to pieces, putting together, and lubricating breech-loading firearms, and for other like uses.

and lubricating breech-loading nrearms, and for obtain like uses.

93 G. H. Wilson and G. E. Pullen, Commercial-road, Middlesex. Improvements in apparatus for securing or fastening window sashes, and an improved bolt, applicable to sash fasteners of all kinds.

934 W. Allan, Sunderland. Improvements in marine steam engines.

935 W. Bayne and O. E. M'Gregor, Wolverhampton. Improvements in carpenters and joiners' planes.

Dated April 2, 1869.

996 G. H. Smith, Colchester, Essex. Improved means and apparatus for indicating when eggs, vegetables, and other substances are sufficiently cooked or heated.

997 J. Bath, King William-street, City. An improved printing and copying or repeating letter press or machine.

998 H. A. Fletcher, Lowes Engine Works, near Whitehaven. Improvements in steam generators.

998 H. A. Fletcher, Lowca Engine Works, near White-haven. Improvements in steam generators. 999 W. Marston, Loughborough, Leicestershire. Im-provements in bolts. 1000 F. Schafer, Piccadilly. Improvements in covers for vessels, and an improved clip for bottles placed in such

vessels.

1001 J. (Cruttenden and T. Wells, Maidstone, Kent. Improved arrangements of mechanism for facilitating voting by ballot, and in the construction of parts of the apparatus in connection therewith.

1002 W. Y. Craig, Harceastle Collieries, Stoke-upon-Trent, and S. P. Bidder, jun, Hillfield House, Mitcham, Surrey. Improvements in safety lamps, and apparatus employed in connection therewith.

1003 D. Osborn, Great Berkhampstead, Hertfordshire. Improvements in apparatus to be employed in concrete building.

building.

1004 S. K. Hoxsie, Philadelphia, Pennsylvania, U.S. A.
Improvements in coal and grain boat elevators.

Improvements in coal and grain boat elevators.

Dated April 3, 1869.

1005 G. H. Ellis, New Barnet, Hertfordshire. Improvements in apparatus for cleaning boots and shoes, knives, &c., applicable also to hair brushing purposes.

1006 M. Wolfsky, Pligrim-street, Ludgate-hill, City. Improvements in locks and fastenings for bags, satchels, boxes, and other like articles.

1007 R. Allan, Kelvindale, Lanarkshire. Improvements in machinery for the manufacture of paper.

1008 D. Nicoll. Caledonian-road, Middlesex. An improved safe for food, and automatic apparatus for generating preservative and other elastic gases to be used in connection therewith, and for other domestic and general purposes.

ourposes.

1009 E. Wilson, Peckham, Surrey. Improvements in electiopedes, parts of which improvements relate to a stochet and treadle motion applicable to various machines.

1010 W. H. Douglas, High-street, Stourbridge. Improvements in the manufacture of jet and other orna-

ments.

1011 J. Howden, Glasgow. Improvements in the materials for preventing the escape of heat from the surfaces of cylinders, boilers, and other vessels or apparatus containing heat.

1012 U. Scott, North-street, Fitzroy-square, Middlesex. Improvements in railway and other carriages, and various parts of the same, some of which may be used for other nurroses.

purposes.

1013 W. E. Broad, Wychdon, Staffordshire. Imments in the construction of loose railway whee

1014 G. F. Griffin, Great George-street, Westminster. Improvements in the permanent way of railways and

namvays.

1015 D. J. Hoare, Princes-terrace, Bayswater. Improvements in atmospheric railways.

1016 S. Sharrook, Liverpoel. Improvements in | the statement of reefs.

1017 F. Boyd, Boston, Suffolk, Massachusetts, U.S.A. Certain new and useful improvements in the construction of breech-loading firearms.

1018 F. W. H. Medhurst, Chancery-lane. Improvements in lamps.

1019 J. G. Tongue, Southampton-buildings, Chancery-lane. Improvements in parasols or umbrellas.

Dated April 5, 1869.

1020 G. A. Ermen, Eccles. Improvements in breech-loading firearms and cartridges relating thereto.

1021 W. Johnson, Elms, Sketty, Swansea. An improvement in machinery for compressing the carbonaceous, resinous, or other combustible substances employed in the manufacture of compressed fuel, which improved machinery may also be employed in moulding clay and other building materials.

uilding materials. 1022 J. Wood, J. Hampson, and L. and G. Fish, Preston.

building materials.

1022 J. Wood, J. Hampson, and L. and G. Fish, Preston. Improvements in looms for weaving.

1023 J. U. Askham, Sheffield. Improvements in the manufacture of anvils.

1024 J. Fletcher, Heywood, Lancashire. Improvements in the construction of firebars to be employed in furnaces.

1025 F. Commasi, Rue du Colysee, Paris. Improvements in obtaining motive power from flow of the sea, and in machinery for applying the same.

1026 W. G. White, Laurence Pountney-lane, City. Improvements in the manufacture of iron or steel safes, safe and strong-room doors, and other like structures, parts of which improvements are applicable to other purposes.

1027 W. Jones and T. Sheffield, Manchester. Improvements in boilers employed for generating steam.

1028 J. Winter, jun., Wardour-street, Soho. Improved apparatus for filling glass bottles and jars with soups, jellies, fruits, and other edibles for the purpose of preserving them, the axid apparatus being also applicable for filling bottles with sauces, wines, spirits, beer, liquors, and other still and effervescing beverages; also machinery, in combination with the above apparatus, for corking or stoppering such said bottles and jars.

1029 C. Cairns, New York, U.S.A. Improvements in heating by steam for manufacturing and other purposes.

1030 J. W. Drummond, Schenectady, New York, U.S.A. Improvements in looms for weaving.

1031 J. Greenslade, Steeple, Essex. Improvements applicable to traction engines.

1032 J. Sterriker, Great Driffield, Yorkshire. Improvements in pressing apparatus for expressing oils and other matters from seeds or other similar substances in which

ments in pressing apparatus for expressing oils and other matters from seeds or other similar substances in which those matters are contained.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office MoneyOrder should be sent, payable to ROBERTSON, BROOMAN, and Co, Patent Department, 166, Fleet-street, London, E.O, to whom all communications upon the subject should be addressed. tions upon the subject should be addressed.

Science and Art.—A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brocches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[ADVI.] SCIENCE AND ART .- A striking instance of the

### MECHANICS' MAGAZINE.

LONDON: FRIDAY, APRIL 16, 1869.

#### THE GREAT INDUCTION COIL.

NE of the greatest scientific wonders even in this wonder-producing age is unquestionably the great induction coil—or inductionably the great induction coil—or inductionium, as the German physicists term it—at the Polytechnic Institution. It is an instrument of remarkable power and capacity, and possesses the highest scientific interest. We possesses the highest scientific interest. We briefly described this apparatus three weeks since, but, as a marvel of science, it deserves a more detailed notice than our time then permitted us to give. In designing this induction coil, which is about six times as large as any previous production of the kind, Professor Pepper's object was to obtain an easily controlled source of electricity, combined with a degree of tension sufficient for the scenic requirements of the Polytechnic. In carrying out this object, the Professor enlisted the services of Mr. Apps, of the Strand, who has himself effected many important improvements in induction apparatus, and to whom is due the construction of the present powerful machine; but, although so extremely powerful, it is nevertheless perfectly safe to the manipulator, so carefully has every contingency of accident been guarded against. The machine consists of an ebonite barrel, 9ft. 10in. in length, supported at each end on two ebonite pillars. The barrel was made at the Silvertown Works, and is the largest ever turned out there. I contains the compound coil, and of itself weighs 477lb., the whole machine weighing 15cwt.

The primary wire is of copper of the highest conductivity 0.0925 in. diam. (B.W.G., No. 13), and 3,770 yards in length; the number of revolutions of the primary wire round the soft-iron core is 6,000, its arrangement being three, six, and twelve strands. The total resistance of the primary coil is 2.201400 British Association units; and the resistances of the primary conductors are respectively for the three strands, 0.733800; for the six, 0.366945; for the twelve, 0.1834725 B.A. units. The soft iron core is composed of straight wires of very soft iron, each wire being 5ft. in length, and 0.0625in. in diameter. The diameter of the bundle of core wires is 4in., and their weight 123lb. The secondary wire is 150 miles in length, 0.015in. (B. W. G., No. 29), diameter, and is covered with silk.
total weight of the wire is 606lb., its electrical resistance 33,560 B.A. units. This secondary coil is 4ft. 2in. long, and the insulation is calculated for safety at 95 per cent. beyond absolute requirement. The secondary wire is insulated from the primary by an ebonite tube 8ft. in length, and lin. in thickness. The condenser is made with sheets of varnished paper and tinfoil, arranged in six parts, each containing 125ft. super, or a total of 750ft. super.

The machine was originally tried with a contact breaker detached from the great coil,

and having an independent electro-magnet; this worked well up to ten Bunsen cells with the great inductorium, but when the battery was increased to thirty or forty cells it became unmanageable. A Ruhmkorff break, with platinum amalgam and alcohol above it, was substituted, which saved the points, but the spirit was now and then violently ejected and set on fire. Professor Pepper then proposed a modification, which has proved successful, remaining in perfect working order during a series of experiments extending over eight hours. The commutator regulating the

is most carefully and effectually insulated from the floor and surrounding apparatus, as are also the separate portions of the appaare also the separate portions of the apparatus from each other. The battery power is at present supplied by forty Bunsen cells, each containing a pint of nitric acid. It is, however, intended to substitute for this, a Grove's battery of the largest size ever made, and which is in course of construction. It will consist of pipeclay cells, 2ft. square upon the sides, and 3in. wide, with walls an eighth of an inch thick of an inch thick.

In working the great induction coil, the sparks obtained from it with five Bunsen cells are 12in. in length; ten cells give sparks 14in. in length; fifteen cells give 17½in. sparks; twenty cells give 21in. sparks; twenty-five cells give 23in. sparks; thirty cells give 23½in. sparks; thirty-five cells give 26in. sparks; forty cells give 27½in. sparks; thirty-five cells give 27½in. sparks; forty cells give 27½in. sparks; forty cells give 27½in. sparks; and with fifty cells, sparks from 28in. to 29in. in length were obtained. After eight hours working, the coil gave, with fifty cells, a spark 25 in. in length. It was also found that of the proportions of the condenser used, one-half gave the longest spark. The spark is not such as is generally produced under similar circumstances, but is a thick wire of light, surrounded by a wide waving flame 2in. or 3in. thick, and, which can be blown aside from the spark. The spectroscope gives a perfectly continuous spectrum, like the light of day, only that it is barred with the bright lines of the substances in combustion. flame of the spark, with a very slight blast of air, rises to, at least, 12in. in height when it is passing about the same distance horizontally.

Besides the gigantic Grove's battery, there

is also a Leyden battery in course of con-struction, the present one being inadequate to represent the full power of the coil. The first part of this battery, consisting of 250ft. super of coated glass, is now nearly completed. There is also a very large and elegant arrangement of Gassiott's cascade in course of construction, which is also to work with the great induction machine, and which will embody several important improvements that have been suggested by Mr. Gassiott. The most recent experiments with the coil have shown that as yet no limit as to the quantity effects can be established, and it is exceedingly probable that by a very few minutes' working, the large coil would charge, at least, 1,000 Leyden jars of very large size. The coil too, is probably destined to throw a new light upon scientific research, and to solve the pro-blem—what is ozone? In reference to the amount of this element, and the density at which it may be produced, very few experi-ments have as yet been made. But enough is seen in the extraordinary reddening effect of the flame of the spark on litmus paper, to show that we are likely very soon to solve the ozone problem.

#### COLLECTING AND UTILIZING SEWAGE.

HE two main points in the sewage question are, the effectual removal of refuse and foecal matter from our dwellings, and its effi-cient utilization upon our lands. Upon these points there exist a great variety of opinions, some advocating one method of removal and utilization, and some another. Into the various methods proposed, suggested, or in use, we need not here enter; they are sufficiently well known to all who know anything at all about the matter. We point to our Metropolitan main drainage as a sufficient answer to the first point in question, and to the Croydon irrigation works as an equally sufficient answer to the second. But it may be said that our cities and towns are not Londons nor Croydons, and that many a cluster of habitations are neither cities nor

sewage? Of course, everybody will say there are many ways of doing that. admit there are, and we will now point out one of them, the most recent that has come under our notice. This is the system of M. Delbriel, which was explained to a meeting of gentlemen practically interested in the sewage question on the evening of yesterday week. The meeting was held at the Inns of Court Hotel, Holborn, the Duke of Castelluccio in the chair. M. Delbriel's system of collecting and utilizing sewage is better known in France, where it is practically applied in several places as vidance a vapeur. It consists in using a traction engine, to which are attached tanks, into which the sewage is pumped by the engine. During the extraction of the sewage, the mouth of the cesspool is covered with sailcloth steeped in sulphate of zinc. The mephitic vapours are drawn off from the tanks by means of pipes which communicate with the engine furnace in which they are burned. By these means, it is affirmed that no unpleasant smell nor noxious vapour ever finds its way to the air, whilst the sewage in the highest condition for fertilizing purposes does find its way on to the lands of the farmers. Depôts are established where the sewage is deposited, and from which it is distributed to the farmers. Or otherwise it is supplied on to their lands direct from the tanks. In all this there sounds to our ears-who have been accustomed to a widely different dealing with the same question-a return to the old cesspool system, the engine doing duty for the horse and men of the old night cart. But it must be borne in mind that with all our sanitary progress there are yet many spots in Great Britain where the system would be a great boon, and to these M. Delbriel proposes its application. That it has proved a great success in France is due to the very different sanitary and agricultural conditions of that empire as compared with the United Kingdom. On the whole, M. Delbriel's Kingdom. On the whole, M. Delbriel's system is well worthy of consideration, and, therefore, we subscribe to the following resolution, which was passed at the meeting in question:—"Considering the present great waste of the sewage of towns, &c., and the necessity of diverting it from rivers and streams, and the value of applying it to the purposes of agriculture, this meeting is of opinion that M. Delbriel's system is worthy the attention of the public, and more especially all persons interested in this important question, and that it is desirable that M. Delbriel should issue a translation of his pamphlet."

#### CLEANING THE EXTERIOR OF HOUSES.

EVERY building in which the constructive material does not constitute to a great extent the ornamental and decorative as well, extent the ornamental and decorative as well, must, in a comparatively brief period of time, present apparent traces of external ruin and decay. A house just completed, of which the walls are covered with stucco, or, in Mr. Ruskin's language, "slime," looks well enough for about a year, if it be erected in London or any of our large provincial towns, where the numerous influences of a mocky and connumerous influences of a smoky and contaminated atmosphere quickly contrive to take the shine off it. Even in more favour-able localities, a "slimed" house cannot be expected to appear decent for more than three years, the term of the shortest lease of tenancy. Where painting is resorted to, the necessity for renewing the "vencering" of the exterior of a building is demonstrated much earlier than in the former instance. At present, provided there is no absolute danger of a house falling down, the owner may please himself about its exterior appearance. He may paint or renew the face of it once a year if he pleases, or he need not do it from the time admission of the battery current is provided towns. Then naturally follows the question it is erected to the day it is pulled or burnt with a locking apparatus, and the whole coil of how to deal with a limited amount of down, if such suits his convenience. It is on this

Digitized by Google

account that the shops and buildings in our streets and thoroughfares present so bizarre and incongruous an appearance. In one case, we have a tradesman determined to go along with the spirit of the age, and putting up a new shop front, and painting his house, in order to bestow upon it a fictitious look of modernism. In the other, either next door or vis a vis, there is to be found an example of the old school, who considers respectability to depend upon small and dirty panes of glass, and his solvency to be in the inverse ratio of the light and air admitted into the interior of his premises. As a consequence, we find a handsome and elegant façade, fit to figure in the chief street of any metropolis, kept in countenance by a murky, dismantled old building that would have been a disgrace to the purlieus of St. Giles in its palmiest days. While builders are bound by tolerably strict regulations respecting the actual erection of houses, and the compliance with sanitary requirements, there is no clause which takes the slightest notice of the maintenance of their work. It may be maintained in a complete state of repair and efficiency, or it may be suffered to fall into decay with impu-

This question has been recently taken into reconsideration by our Gallic neighbours, and towards the end of last year an order was issued by the Prefect that the façades of all dwellings in the 3rd, 4th, 9th, and 10th divisions (arrondissements) of Paris should be periodically cleaned, the law to take effect on and after May 1 of the present year. So far back as 1852 there was a law promulgated to the same intent, but its injunctions have been so frequently neglected that the authorities have thought it requisite to call prominent attention to it by issuing what might be termed a new edition. The old Act ran as follows :-- "The façades of houses are to be kept in good repair. They are to be rubbed, plastered, painted, or the surface either renewed by cleansing in some manner or another, at least once in every ten years, at the expense of the proprietor. A noncompliance with this regulation will subject the offending party to a fine not exceeding £5." Although the legislation thus insisted on the general principle, the particular modus operandi, or means of putting the principle into execution, was left altogether to the discretion of the owner. The favourite method which has been successfully practised for the last two years, is that of cleaning the walls by the employment of a jet of water projected under steam pressure. There are many advantages steam pressure. attached to this plan of proceeding. It not only restores the façades to their original appearance, but it does not injure the more delicate, decorative, and ornamental portions of the building, neither does it destroy the then protecting coat which the stone has received from the influence of the atmosphere. By this method we ensure the fulfilment of several valuable conditions. First, cheapness; second, the preservation of the more fragile and sculptural work upon the edifice; and, third, universality of application. If, in addition to the enforcement of some regulation of this description, with respect to the buildings in our principal streets and thoroughfares, those in our narrow courts and alleys were brought under the same jurisdiction, the result, in a sanitary point of view, might not be inconsiderable. It has been calculated that were the exterior of the buildings in London kept in a clean fresh condition, instead of being nearly black from top to bottom, there would be a gain of nearly half an-hour's daylight in every twenty-four hours.

### THE INSTITUTION OF NAVAL ARCHITECTS.

large vessels in Her Majesty's navy. favourable report on the proposed method, by Sir W. Armstrong and Mr. Penn, has led apparatus, constructed from Captain Inglefield's designs, being fitted to H.M.S. "Achilles." Several methods have already been proposed, and some of them successfully put into practice, for bringing hydraulic or steam power to bear on the tiller. of these, steam has been the prime mover. The "Minotaur," for instance, has an hydraulic steering apparatus, worked by a donkey engine, which has always to be kept at work pumping water to waste, so as to insure the assistance of the apparatus when needed. Here is a decided want or economy.

the chief features of Captain Inglefield's plan

the chief features altogether. The motive power he resorts to is the hydrostatic pressure at the lowest point of the ship's bottom. The water is admitted here through a Kingston valve at a depth of 20ft. The pressure of this water, acting on a piston of 36in. area, works a reciprocating pump. From this pump a couple of wrought-iron 2-inch pipes are led to two cylinders, one on each side of the lower tiller, these pipes being constantly full. By means of a slide contained in a slide box, and worked by a wheel in the pilot house, the engine is set in motion, and the hydraulic pumps brought into action. This slide can be made to lock the water in the two cylinders, and so the helm may be kept over at any angle that is desirable. Now, all this is very nice. We have been working our helm at no expense to ourselves. This is certainly economy. In fact, it is too good to be true. How are we to account for the apparent impossibility? It is this—the ship is now deeper in the water, owing to the weight of the water we have admitted through the valve. All this water must be pumped out again. However, on this score, Captain Inglefield quietens our apprehensions. He tells us that the "Warrior's" helm can be put hard down every fifteen minutes for ten days, by admitting no more water than is admitted into her condensers in the course of one hour. getting rid of this water, therefore, cannot offer much difficulty, nor can it be a serious objection to this method. The chief advantage of Captain Inglefield's method can be put thus: the power that he relies on is that of a faithful servant, who, though he costs next to nothing to keep, is always wakeful ready, and fresh, while the power relied on in other methods is that of a pampered menial, who eats his head off in his idleness, and when he is wanted on an emergency is sure to be caught napping.

At the meetings of the Institution, last year, Mr. Saxby read a paper on testing iron by magnetism. This year the same subject was followed up by Mr. Saxby in a further paper, "On the Qualities of Boiler Plates. Last year, the Secretary for War allowed Mr. Saxby to make a course of experiments at the Enfield Factory, and, if successful, Mr. Saxby was to have his expenses paid. This reminds us of the old quack's cry, "No cure, no pay!" In this case, the cure, so to speak, has been so far successful that the patient has actually paid the fee. An example will best show the nature of Mr. Saxby's investigations at Enfield, and the success attending them. One individual barrel was selected as the subject of experiment. This was tested by the magnet, first, as it came from the fire; again, a second time, after it had been turned up in the lathe; and, a third time, after it had been ground and bored. In each stage the magnet pointed out a flaw not far from the muzzle, and running down the barrel for a few inches. In short pieces, cut off from the barrel, and examined care fully, what are technically called "greys" were discovered in flaws in the metal. If

the metal, but the lynx-eyed magnet is not to be baffled by a stone wall, or a few inches of iron. It affords a means of detecting flaws, which at present we have no other means of ascertaining.

During the past year, Mr. Saxby has been devoting his attention more especially to applying his magnetic test to boiler plates. The master boiler maker in one of the Government yards supplied Mr. Saxby with a carefully-selected piece of a partly-used plate, that had passed through all the Admiralty tests. This specimen was not a foot square, and was given as a sample of the very best rolled plate that could be got for love or money. The magnet assailed this champion of a plate, and with a quickness that was almost suggestive of error, pointed out a weak point. However, the place was marked, and the master boiler maker, on re-examination, was forced to confess that his specimen plate was not without its weak point. A plate, formed of three, rolled together, is transparent to the magnet's eye, and it will tell whether the middle layer of the sandwich is as good and sound as the outer layers. In fact, the author of the paper says that no trick of trade like this can escape detection by the magnetic test. In these days of freedom of thought and liberalism, we are taught to put no faith in tests, and to disbelieve all claims to infallibility. Here, however, we find a gentleman putting forward a test which we cannot but allow has some virtue in it, and one for which he claims the higher attribute of infallibility.

### THE ROYAL INSTITUTION.

AST week, at the Royal Institution, Pro fessor Robert Grant, F.R.S., Superin tendent of the Observatory at Glasgow, gave the first of a series of nine Tuesday afternoon lectures upon "Stellar Astronomy." opening lecture dwelt principally upon the historical part of the subject and upon elementary facts. On the following Thursday, Professor Tyndall delivered the first of a course of lectures upon "Light." His opening address also was of a very elementary character, but he introduced a new experi-ment to prove that the angle of incidence of light is equal to the angle of reflexion. A rod of brass, graduated in inches, was supported in a horizontal position, and from its centre a thread, drawn tight by a plummet descended into a basin of water, coloured with ink in order to get rid of all but surface reflexion. A small dimple was necessarily made at the place where the thread entered the ink. A small paraffin lamp was then placed with its flame nearly touching the rod, and at about a yard from the central thread. Upon bringing the eye along the other end of the rod, and watching the small dimple in the water, it was seen to be most brilliantly illuminated when the eye was at the distance of a yard from the centre of the rod, thus proving that the angle of incidence is equal to the angle of reflexion. To whatever distance the lamp was shifted from the central thread, the eye had to be placed at a similar distance on the other side to get the most brilliant reflexion. On Friday evening, Dr. Carpenter, V.P.R.S., lectured upon "The Temperature and Animal Life of the Deep Sea. The lecture was highly interesting, but we are obliged, for want of space, to defer our notice of it until next week.

### HANCOCKS' NEW SCREW PROPELLER.

[N the MECHANICS' MAGAZINE for September 18 last we described and illustrated CAPTAIN INGLEFIELD, R.N., read a paper on a method proposed by him for applying hydraulic power to the steering of Here the "greys" lay hid in the thickness of recorded a series of experiments which had

Digitized by GOOGLE

been made with it against a Smith screw, and which were highly in favour of the Hancock screw. We are glad to be able to state that recent and independent trials of the system in Holland have confirmed the results of the experiments made in England. It appears that M. Van der Made, of Dordrecht, ordered a screw from Messrs. Hancock for a steam launch 30ft. long and 6ft. beam. The engine The engine has a cylinder 4in. diameter and 7in. stroke, and the propeller with which she was originally fitted was a Smith screw, 30in. diameter and 3ft. pitch. The steam was used at 70lb. pressure. The Hancock screwis 28in. diameter and 28in. pitch, and the result of working is found to give an increase of 25 per cent. in speed against the tide over the Smith screw, the conditions of working being the same in both cases. These results are stated in a letter now before us from M. D. J. P. Van der Made, who is a son of the proprietor of the launch, and is at present a student at the Royal School of Naval Architecture, South Kensington. This result is highly gratifying, because with 2in. less diameter in the Hancock screw we might not have been surprised at equal or even inferior results to the Smith screw. But it is a great point in its favour that it made an absolute gain of 25 per cent. With such results, the Hancock screw has a promising future before it, and we shall be greatly deceived if it does not realize our predictions of success.

# THE NEW INSTRUCTIONS OF THE GAS REFEREES.

THE requirements of the Gas Acts of 1868 have necessitated the preparation of a new set of instructions by the gas referees, and this time, we presume, we are not wrong in concluding that they are definitely issued to the examiners. These revised directions offer but little that is new, and we only refer to them for the purpose of taking up one or two points which we left unnoticed in our last remarks. Let us, first, however, congratulate the referees on the progress they have made in chemistry during the last six months. Within this period they have been converted from the old to a new (not the newest) system of chemical nomenclature. What they called sulphate of baryta in October, 1868, is sulphate of barium in April, 1869. The equivalent weight of the substance, which was 117 in October, is now 116.5, in accordance with more recent determinations. Next October we shall probably arrive at barium sulphate, and find the atomic weight adjusted to the very latest deter-mination of Stas calculated to two or more decimal places. This, at all events, indicates a willingness to receive instruction, which is beyond all praise.

One point to which we have not before alluded is the introduction of corrections for variations of temperature and atmospheric pressure, in determining the quantity of gas burnt, in estimating its illuminating power and purity. This, at first sight, gives an appearance of wonderful accuracy, but a little reflection shows it to be exceedingly absurd. In the first place, no regard is paid to these variations in charging the consumer for his gas. A cubic foot, as measured by the meter, is charged as a cubic foot, whether the barometer stands at 28in. and the temperature is 82deg. Fah., or whether the pressure is 31in. and the temperature 40deg. Fah., just as a gallon of spirit is a gallon of spirit, whether it is measured in the depth of winter or the height of summer, although everybody knows that a considerable change of volume takes place in spirit within the range of temperature of the two seasons. On this ground alone the introduction of these corrections is distinctly objectionable, but we object to them for the further reason that they do not and cannot conduce to accu-

gas, passing through a meter at the rate of 5ft. per hour assumes the temperature of the surrounding media, and we know that it is subjected to a pressure differing some-what from that of the atmosphere. This, then, and the fact that the corrections are only made for differences of two degrees of temperature, and tenths of an inch of pressure, completely takes away the appearance of scientific precision from the results obtained. But it is, when we come to the instructions for sulphur determinations that the absurdity comes out most strongly. The experiment goes on for twenty-four hours. The barometer and thermometer are read once each day, and the mean of these two observations is taken to represent the pressure and temperature of the twenty-four hours. But suppose-and it is no violent supposition—that in the course of the twenty-four hours, the barometer sinks 0.5 and rises again 0.6, the thermometer, in the same time having a range of 10deg., what idea would the mean of two such readings as these give of the average pressure.

Such is the statement we should find in the examiner's record, but in the same time, the maximum and minimum readings have been as follows:—

It is clear, that these latter calculations would be much nearer the truth than the former, but, after all, might be very wide of the actual truth. We shall probably be told that, on the whole, it will be found perfectly fair, the governed every entitle hing all night fair-the general average will bring all right. No doubt of it; and why give all this unnecessary trouble. If the referees had ascertained the mean pressure and temperature in London for the past year, they would probably have found that the pressure was 29.8, and the temperature nearly 52deg. On looking to tables, we find that to correct the volume of gas under these conditions, 9 have to be added to 1,000, a result which we know to be scientifically valueless, but which would be rather against the companies as regards illuminating power. As, however, the temperature will always be taken in the photo-As, however, the temmeter-room, the corrections are certain to be on a vast majority of days in favour of the companies.

There is one other point, with respect to these sulphur determinations, which we must notice. The referees direct two experiments to be made simultaneously, and the mean of the two results to be taken, to express the amount of sulphur in the gas. Now, as everybody knows that some sulphur always escapes in the process they employ, and as the apparatus they supply is singularly well adapted to facilitate the escape of a great deal; and as, moreover, the sulphur found can only come from the gas burned, any reasonable man would conclude that the maximum result must be nearest the truth. So, no doubt, the referees well know, but they do not act on their conviction.

they do not act on their conviction.

We come next to the ammonia determinations, which we must dismiss very briefly. We will suppose the gas to contain the five grains of ammonia in 100ft., as permitted, and that 20ft. have been burned. Thus the liquid in the cylinder will contain one grain of ammonia. Half this liquid is to be set as is distinctly objectionable, but we is distinctly objectionable, but we be is distinctly objectionable, but we be introduction of these corses is distinctly objectionable, but we be introducted in the further reason that o not and cannot conduce to accultions to be rigidly accurate, which is suppossing the test solutions.

ing a good deal, it is no reflection on the most careful examiner to say that he is never likely to hit the exact point of saturation. Some amount of error is inevitable, and in calculating the results for 100ft., this error will be multiplied just fifty times. The error, we need hardly say, is certain to be in favour of the gas company. It must not be supposed, from what we have said, that we at all sympathise with the offensive agitators who are continually worrying the gas companies, and striving to depreciate the value of their property. All we wish for is to see a sound, scientific, and fair system of gas testing; and this, we hope, the referees will in time supply us with. We can afford no more space for this subject to-day, but some further practical considerations remain, which we shall refer to on another opportunity.

METEOROLOGICAL RESEARCH BY AID OF THE ELECTRIC TELE-GRAPH.—No. I.

METEOROLOGY in its largest sense is a subject which althous IVI subject which, although great collections of observations have been made, is hardly yet a science; yet the interpreters of this part of the book of nature have already begun to spell out some phrases, which show that the language is not wholly unintelligible. And here, therefore, we may go on hopefully, recollecting always that the collection of facts is a matter of comparatively small value, except we can also trace in them some rule or order. The mere gathering of raw facts may be compared to the gathering of the cotton from the tree. The separate filaments must be drawn into a connected thread, and the thread woven into an ample web, before it can form the drapery of science." These words were addressed by the celebrated Dr. W. Whewell to the British Association, in 1841, but they apply with equal force to the present time, and should be on the mind of every meteorologist. In 1848, a short but remarkable paper was read to the British Association, by John Ball, M.R.I.A., which, as being probably the earliest distinct state-ment of the advantages likely to result from pressing the electric telegraph into the service of meteorology, may be reproduced with interest.

What is properly termed the weather, is a general expression for the physical condition of the atmosphere with reference to heat, pressure, moisture, and the velocity and direction of its motion. Two classes of causes determine these conditions at any given point of the earth's surface. The first class may for short periods of time be considered as constants, depending on the position of the point of observation on the globe, and the physical conformation of the adjoining districts. The second class, upon which the proverbial uncertainty of the weather depends, arises from the influence exerted by each portion of the atmosphere upon those surrounding it, by virtue of which a disturbance of equilibrium at any one point is rapidly propagated in all directions. In common language, this is expressed by saying the direction of the wind is at once the cause and the indication of changes of the weather. However far we may be from a general solution of the problem of atmospheric disturbances, meteorologists have made considerable progress in tracing the connection between successive states of the weather, owing to the mutual influence of contiguous portions of the atmosphere. These cases have been studied a posteriori, comparing the known results with observations extending over considerable areas. Now that we have the means of receiving information in an indefinitely short space of time by the electric telegraph, these problems, under favourable circumstances, may be studied a priori. In London, we may receive instantaneous intelligence of the condition of the atmosphere, as to the five above-mentioned elements, from nearly all the extremities of Great Britain. With a delay of about four hours, we can the similar intelligence from the western part of Ireland, and with a still shorter delay, our communications may extend to the centre of France, the banks of the Rhine, and even to Hungary and Poland. I do not pretend to say that with such elements for calculation, we should at once be enabled to predict changes in the

determinations thus arrived at would possess a high degree of probability. The ordinary rate at which atmospheric disturbances are propagated does not seem to exceed twenty miles per hour; so that with a circle of stations extending about 500 miles in each direction, we should in almost all cases be enabled to calculate on the state of the weather for twentyfour hours in advance.

Very remarkable it is that this paper shadowed forth so completely the actual system of telegraphing the weather carried out by Admiral Fitzroy in 1860; and still more remarkable is the fact that the results anticipated from the employment of the telegraph in meteorological research should have been fully realized in the Admiral's weather forecasts and storm warning signals. The only wonder is that the plan was suggested so many years before its adoption, more especially as the idea of telegraphing the state of the weather was familiar to men's minds, and repeatedly brought into public consideration.

In the "Annuaire Meteorologique de la France" for 1849, M. C. Martins urged the establishment of meteorological stations at the French telegraph offices; adding, "some day their employee, habituated already by the nature of their duty to exactness and observation, will be charged with the duty of reading and using meteorological instruments.' recommendation was, however, not carried into practice until 1857, when M. Leverrier, the Imperial Astronomer, arranged a meteorological service for France, by the agency of the telegraphs, for the purpose of sending around the coasts intelligence of existing weather. Twenty-four towns suitably chosen upon French territory, and provided with the requisite instruments, sent every morning to the Observatory at Paris the state of the sky, the direction and force of wind, the temperature, and the barometric pressure for the whole extent of France. Soon after, an interchange of these telegraphic communications was effected with foreign observatories.
Madrid, Lisbon, Turin, Florence, Rome,
Brussels, Copenhagen, Stockholm, Haparanda, Warsaw, St. Petersburg, and Moscow, transmitted observations. Finally, Constanti nople and Algiers were in the exchange. All these observations were published daily in the "Moniteur," and reproduced by the daily journals. The interest taken in the meteorological returns is sufficiently evinced by the continuance of their publication to this day. To the mere newspaper reader, probably the thermometric observations are the most noteworthy, as the vicissitudes of temperature are frequently very striking over so large an area. But to all classes engaged in commerce and agriculture, this quick intelligence of existing weather must have been of great advan-

The system of giving warning of storms by signalling their advent from place to place was suggested while the old semaphoric telegraphs were in use; and the idea of effecting this object occurred at once to various persons in England and America when electricity became man's messenger. Captain Maury, then Director of the Observatory at Washington, in his well-known "Sailing Directions, edition of 1858, emphatically brought the subsubject forward in these words: -- "With a properly devised system of meteorological observations to be made at certain stations whereever the telegraph spreads its meshes, and to be reported daily by telegram to a properly organized office, the shipping in the harbours of our seaport towns, the husbandman in the fields, and the traveller on the road, may all be warned of every extensive storm that visits our shores, and while yet it is a great way off."

The British system of telegraphically communicating meteorological observations from distant stations to a central office in London had its origin at the meeting of the British Association for the Advancement of Science, held at Aberdeen in 1859 under the presidency of the lamented Prince Consort. The consideration of the subject resulted in the fol-

lowing resolution :- "The Committee of the Section of Mathematical and Physical Science, having represented the probable importance of occasional telegraphic communication between a few widely-separated parts of Great Britain and Ireland, by which warning may be given of storms, the General Com mittee recommends application to the Board of Trade for such an arrangement as may further this object authoritatively." Early in the following year, two meetings were held at Buckingham Palace relative to this subject, and it was decided that Admiral Fitzrov. the chief of the Meteorological Department of the Board of Trade, and who was also a member of the Council of the British Association, should be directed to organize a plan and carry it out as an experiment. When and carry it out as an experiment. the British Association met at Oxford in July, 1860, Admiral Fitzroy read a paper on "British Storms," and explained the measures proposed for meteorological telegraphy. These proposals obtained approval; there was no opposition. Thus supported, the Admiral at once put his plan in operation. In September of the same year, twenty selected telegraph stations, situated upon the coasts of the British Isles, were furnished with the necessary instruments, and com-menced making and reporting meteorological observations. Arrangements were also com-pleted with the French Government for a Arrangements were also commutual exchange of certain observations daily. The publication of the daily observations thus obtained was at once commenced in the newspapers; and the public was, for the first time, put in possession of reliable and accurate reports upon the daily weather, which were universally appreciated. The vague and unreliable statements of the prevailing wind and weather, hitherto received by telegraph, and published in the newspapers by private agency, had long been deemed insufficient and unsatisfactory. The new system of meteorological telegraphy thus commenced by Government has continued uninterruptedly to the present time.

As we have seen, it was from the first contemplated that simultaneous observations, rapidly transmitted to the central office, would afford ample prevision of dangerous winds and storms. The possibility of effecting this object was apparent to Admiral Fitzroy, for his previous investigation into the characteristics of British weather had led him to conclude that such observations were capable of yielding information sufficiently prognosticative to enable notice of approaching storms to be sent to all the coasts in time to allow of preparation being made for their advent. Accordingly, he proceeded to devise and inaugurate a scheme by which such information might be most simply signalled at the seaports and coastguard stations. first storm-warning signal was made in February, 1861, to the north-east ports. It was derided and disregarded at the Tyne ports, and on the three following days awful losses of ships and lives occurred on the east coast of England. The system of storm signals thus auspiciously inaugurated gradually gained the confidence of the seafaring community, and developed its accuracy and utility.

THE Emperor of the French recently examined THE Emperor of the French recently examined the Henry breech-loading rifle, which was introduced to his Majesty by Mr. E. H. Newby, of King William-street, City, on behalf of the inventor. The Emperor was accompanied by his Minister of War, Marshal Niel, and both readily understood the construction and manipulation of the weapon. The Emperor expressed himself as being much pleased with the working of the rifle, as did also Marshal Niel. Mr. Newby, at the same time, introduced to His Majesty's notice a new cartridge pouch, the invention of Major-General Morris, of the United States Army, the European agency of which has States Army, the European agency of which has been placed in Mr. Newby's hands. Both the Emperor and his minister appeared pleased with the arrangement of the pouch, and, at the close of the interview, his Majesty intimated that it had given LONG AND SHORT IRONCLADS. BY MR. E. J. REED, C.B.

(Continued from page 258.)

S far as our experience goes, then, I am warranted A in making the assertion, that in armoured ships, as the extent and thickness of the armour to be as the extent and thickness of the armour to be carried are increased, the proportion of length to breadth should be diminished, and the fulness of the water-lines increased; and that the shorter, fuller ship can be propelled at as great a speed as the longer finor ship with about the same, or only a little greater, horse power. The constants of performance will undoubtedly be lower in the shorter ship; but they are only hymothetical standards of merit and they are only hypothetical standards of merit, and the benefits in point of first cost, handiness, and maintenance, resulting from moderate proportions, are tangible facts, far outweighing in importance, the small economy of steam power resulting from the adoption of greater proportions and fineness of

One other point requires attention, when we are dis-One other point requires attention, when we are dis-cussing the propriety of building very long ironclads— the fact that in such ships the proportion of frictional resistance to direct head resistance becomes consider-ably increased. It appears probable, even, that if very extreme proportions were adopted, the advan-tages resulting from the reduction in head resistance would be more than counterbalanced by the increase in frictional resistance. To illustrate this statement, in frictional resistance. To illustrate this statement, I will suppose a fully armoured ship to be lengthened amidships, and made finer at the extremities, with a view to increased speed in proportion to engine power. In such a case, a great weight of armour would be added; the strength of the hull proper would require to be increased; and the immersed surface would be made so much greater, as to render the residual to the strength of the str surface would be made so much greater, as to render it questionable whether the saving in horse power, or the increase of speed, if any, would be at all conmensurate with the increased cost, or make amends for decreased handiness. Adding to this, the consideration that a greater area of immersed surface means a greater area subject to fouling, and that one of the chief causes of falling off in speed of a sea-going iron-built ship is foulness of bottom, we may, I think, fairly conclude that this is a feature of the question which ought not to be overlooked. which ought not to be overlooked.

That this is so will, perhaps, appear more clearly ships. Before doing so, I would observe that the advocates of long ironclads have at various times urged the importance of increasing the proportions borne by the displacement and the midship section to the indicated power, and have declared our recent ironclads to be wanting in these, which they consider the "chief elements of naval architecture." Having the "chief elements of naval architecture." Having so fully stated my own opinion on this matter in a previous part of this paper, I need hardly say that in using, as I shall do, these measures of efficiency, I only wish to make a comparison between two long ships, in a manner of which those who favour long ironclads must approve, and that I by no means agree to this method of comparing the merits of armoured ships.

The trials to which I refer, are those which took The trials to which I refer, are those which took place in the spring of last year, in which the "Warrior," "Minotaur," and "Bellerophon" were engaged. Taking the six hours' trials at see of the two long ships, it is found that the proportion of horse power to displacement in the "Minotaur" was 1,608 to 1,000, and in the "Warrior" 553 to 1,000, while the proportion of horse power to midship section immersed was 468 to 100 in the "Minotaur," and 404 to 100 in the "Warrior." In other words, the horse power is less per tan of displacement and section immersed was 468 to 100 in the "Minotaur," and 404 to 100 in the "Warrior." In other words, the horse power is less per ton of displacement, and per square foot of midship section in the "Warrior," than in the "Minotaur," although the latter is the longer ship, and has the greater proportion of length to breadth. It is proper to state that the "Minotaur" steamed faster than the "Warrior," so that her proportion of horse power was, on that account, somewhat greater than that of the "Warrior;" but in order that the proportionate expenditure of power might be the same in the two ships, the "Minotaur's" indicated power would have to be diminished by from 400 to 500 horse power, which is doubtless a greater diminution than would be necessary if the "Minotaur" were driven at the "Warrior's" speed. Here, then, we have a result which follows from the adoption of a standard of merit brought forward by the advowe have a result which follows from the adoption of a standard of merit brought forward by the advo-cates of long ironclads, but which goes against the theory that increased length and proportions tend to increased economy of steam power. I shall be glad to see this seeming contradiction explained, if that be possible; for my own part, I am inclined to think that these facts are confirmatory of the opinion previously expressed, that in very long ships the increase of frictional resistance is so considerable as to become, at least, as important as the decrease in direct head resistance. At the same time, I do not wish to appear to base a general theory on one or two trials; and there can be little doubt that limits do exist at which the increase of length ceases to be beneficial, whether these limits have as yet been reached or not.

reached or not.

In the course of last year, special attention was drawn to the relations which should subsist between the form and dimensions of ironcled ships, and the weight of material in the hull, in a paper read by me

before the Royal Society, and since published in their "Transactions." By the phrase "weight of material," I mean the weight of hull per unit of surface, say, per square foot, and when the armour is included, this is very different in different ships, varying with the extent and thickness of the armour. The methods and arguments of the paper are, in reality, applicable to both completely and partially armoured ships, including, in the latter class, ships like the "Warrior," without any protection at the extremities, and the very much more efficient ships with armour belts, and central, bow, or stern batteries. In order to make a fair comparison, however, between ships having different arrangements and thicknesses of armour and backing. I have thought it proper to distribute the total weight of protecting material over the whole length of the broadside in each case; thus, in fact, turning all ships into equivalent, but completely protected ships, for the purpose of comparison. By this means, a fair idea can be obtained of the relative defense are taken to compare their performrison. By this means, a fair idea can be obtained of the relative defensive powers of the ships considered before any steps are taken to compare their perform-ance under steam. To afford a general view of the methods employed, and the results arrived at, I have given the following abstract, which is a reprint of that sent to the Royal Society.

Abstract of Paper sent to the Royal Society "On the Relation of Form and Dimensions to Weight of Material in the Construction of Ironclad Ships.

The object of the paper is to show that the proportion of length to breadth in a ship, and the form of her water lines, should be made in a very great degree dependent upon the weight of the material of degree dependent upon the weight of the material of which her hull is to be constructed—that an armourplated ship, for example, should be made of very different proportions and form from those of a ship without armour, and that as the extent and thickness of the armour to be carried by a ship are increased, the proportion of length to breadth should be diminished, and the water lines increased in ful-

ness.
It is highly desirable that this subject should receive the attention of men of science, not only because it bears most directly upon both the cost and the efficiency of future ironclad fleets, but also because it opens up a theoretical question, which has because it opens up a theoretical question, which has hitherto, the author believes, received absolutely no consideration from scientific writers upon the forms and resistances of ships, viz., the manner in which the weight of the material composing the hull should influence the form. Prior to the design of the "Bellerophon," the forms of ships were determined in complete disregard of this consideration, and even the most recent works mon the subject mined in complete disregard of this consideration, and even the most recent works upon the subject incite the naval architect to aim always at approaching the form of least resistance. The investigations given in the paper show, however, that the adoption of a form of least resistance, or of small comparative resistance, may, in fact, lead to a lavish outlay upon our ships, and to a great sacrifice of efficiency; while, on the other hand, the adoption of a form of greater resistance would contribute in certain classes greater resistance would contribute in certain classes of ships to great economy and to superior efficiency.

of ships to great economy and to superior efficiency.

In order to indicate clearly, but approximately only, the purpose in view, the author first considers the hypothetical cases of a long and a shorter ship, both of which are prismatic in a vertical sense. The length of the long ship is seven times its breadth, and its horizontal sections consist of two triangles set base to base. The length of the short ship is set base to base. The length of the short ship is five times its breadth, the middle portion being parallel for two-fifths of the length, and the ends being wedge shaped. It is assumed also, that at a speed of 14 knots, the long ship will give a constant of 600, and the short ship a constant of 500 in the Admiralty formula:— Admiralty formula:—
Speed 3 × Mid. Section

being weightless.

Indicated horse power.

The draught of water is in each case 25ft., and the total depth 50ft.

It is taken

It is taken for granted, that the form of the long ship has been found satisfactory for a ship of such scantlings that we may consider her built of iron of an uniform thickness of 6in., the top and bottom

an uniform thickness.

Now let it be required to design a ship of equal speed, draught of water, and depth but of such increased scantlings (whether of hull proper or of armour) that the weight shall be equivalent to an uniform thickness of 12in. of iron, the top and bottom being weightless as before. First, the new ship has the proportions of the long ship given to her, and secondly those of the shorter ship. In each case the engines are supposed to develope seven times their nominal horse power, and to weight (with boilers, waters, &c.), 1 ton per nominal horse power. The coal supply in each case equals the weight of the engines, so that both ships will steam the same distance at the same speed. But as the equipment of the smaller ship will be less weighty than that of the larger ship, we will require the larger ship to carry 2,000 tons, and the smaller 1,500 tons additional weight.

Assuming the breadth extreme in each case to be

Assuming the breadth extreme in each case to be the unknown quantity, we can, from the Admiralty formula given above, deduce an expression for the indicated horse power; thence under the assumed

conditions the weights of engines and coals can be found; and these being added to the weights of hull (calculated on the assumption that the sides are of expression for the total displacement, in tons, of each ship. Another expression is found for this displacement by finding the weight of water displaced. The two expressions are equated, and a quadratic equation is formed, from which the breadth extreme is determined, and from it all the

other values can be found.

The accompanying table shows the results obtained by this method of the two classes of ships:—

	ĺ	Long Ship.	Shorter Ship.
Nominal horse power Indicated Weight of hull , engines , coals		\$81ft. 88 1,850 H.F. 9,450 " 12,570 tons. 1,350 " 2,000 " 17,270 "	342ft. 68j, 1,337 H.F. 9,359 7,576 tons. 1,337 1,500 11,750

It will, therefore, be seen that by adopting the proportions and form of the shorter ship, a ship of the required scantlings and speed will be obtained, on a length of 342ft., and a breadth of 68½ft.; whereas if the proportions of the long ship are adopted, the ship, although of the same scantlings and speed only, will require to be 581ft. long and 83ft. broad, the steam power in both cases being as nearly as possible the same.

cost. croad, the steam power is some cases soing as nearly as possible the same.

Considerations of this character, worked out more fully, led the designer of the "Bellerophon" to depart so considerably from the form and proportions of the "Minotaur."

The next part of the investigation is based upon the official reports of the measured mile trials of the "Minotaur" and "Bellerophon," when fully rigged, and upon calculations made from the drawings of those ships. It is assumed that a primmatic vessel having the same mean draught as each of these ships, those ships. It is assumed that a prismatic vessel having the same mean draught as each of these ships, and having the same form and dimensions as the mean horizontal section—which equals the mean displacement in cubic feet, divided by the mean draught of water—will give the same constant as the ship herself at the assumed speed of 14 knots, which, as nearly as possible, equals the speed obtained by both the "Minotaus" and the Bellerophon" on the measured mile. For each ship the weight of the armour and backing is supposed to be uniformly distributed over vertical prismatic sides of the dimensions of the armoured sides, and the weight of hull is similarly distributed over vertical prismatic sides of the dimensions below water of the mean horizontal section, and above water of the mean horizontal section, and above water of the mean horizontal section, and above water of the same constants of performance as the ships. The detailed calculations in the paper show that the weight per square foot of the material in the hulls of the two ships, when distributed over the sides of the representative prismatic vessels, is very nearly the same for both, and the same holds the sides of the representative prismatic vessels, is very nearly the same for both, and the same holds with respect to the weight per square food of armour and backing. The "Minotaur" is rather heavier in both respects, but for the reasons given in the paper, the means of the values found for the two shaps are en, and are found to be

armour and Weight per square foot of hull =11 ton. backing .

The questions next considered are these :- presuming it to be necessary to build another ship which shall also steam 14 knots, carry the same proportionshall also steam 14 knots, carry the same proportionate supply of coal to engine power, and proportionate quantities of stores, but shall have her armore and backing of double the weight of armore and backing of the "Bellerophon" and "Minotaum," then, first, what will be the size, engine power, and having the same mean draught and depth of armour; and, second, what will be the size, engine power, and having the same mean draught and depth of armour; and, second, of the "Bellerophon" type, and having her mean draught and depth of armour; this conclusion implying of course that the same constants of performance as draught and depth of armour? this condition implying of course that the same constants of performance as before will be realized in each case. On assessme of the great disproportion in size between the two types of ship, it is obvious that the smaller one will require much less weight of equipment. It is assumed, therefore, that the additional weights of the smaller ship (exclusive of engines, boilers, and coals), amount to 700 tons, and those of the larger ship to 1000 tons. The developed power of the engines, proportionate supply of coal, and the weight of engines, &c., are taken exactly the same as in the hypothetical case first given. first given.

By proceeding with the investigation for each case By proceeding with the investigation for each case in a way similar to that sketched for the hypothetical ships, only treating the breadth extreme of the mean horizontal sections of the new ships as the unknown, the following results are obtained:—The new ship of the "Minotaur" type which fulfills the required conditions will be nearly 490ft. long, 72 ft. breadth extreme, and have a total displacement of 14,253 tons, whilethe new ship of the "Bellerophon" 70,000 of the above-mentioned guns.

type is 380ft. long, 71ft. breadth extreme, and has type is scott long, the breadth extreme, and has a total displacement of 10,950 tons. It thus becomes obvious that a correction is needed in the weight per square foot of hull in the new ship of the "Minotaur" type, as her length has been so greatly hereased; it is considered that an increase of at Mereased; it is considered that an increase of at least 10 per cent, is required, and this is the allowance made. On the other hand, the new ship of the "Betterophon" type is still shorter than the "Minotaur" herself, and the displacement is not much greater than the actual displacement of the "Minotaur," so that so correction is needed in her weight per square foot of hull. When the correction has been made for the new ship of the "Minotaru" type, the final results in round numbers are as follows for the two classes of ship:—

	New ship of "Minotaur" type.	New ship of "Bellerophon" type.
Length Breadth Tonnage Nominal horse power Indicated Weight of hull " armout"	510ft. 75 ,, 13,770 tons 1,080 H.P. 7,560 ,, 7,100 tons 5,190 ,,	380ft. 71 ,, 8,620 tons 1,080 H.P. 7,560 ,, 4,460 tons 8,630 ,,
backing ) ,, engines and coals ,, stores carried Displacement	2,160 ,, 1,000 ,,	2,160 ,, 700 ,,

Taking the cost per ton at £55 (which is the average cost per ton of tonnage for the hulls of armour-clad ships), the saving made by adopting the new ship of the "Bellerophon" type would amount to £283,256, or considerably more than a

amount to £25,250, or considerably more than a quarter of a million sterling.

It must also be considered that the ship of the "Bellerophon" type would cost less for maintenance and repair, and be much handier in action.

(To be concluded in our next.)

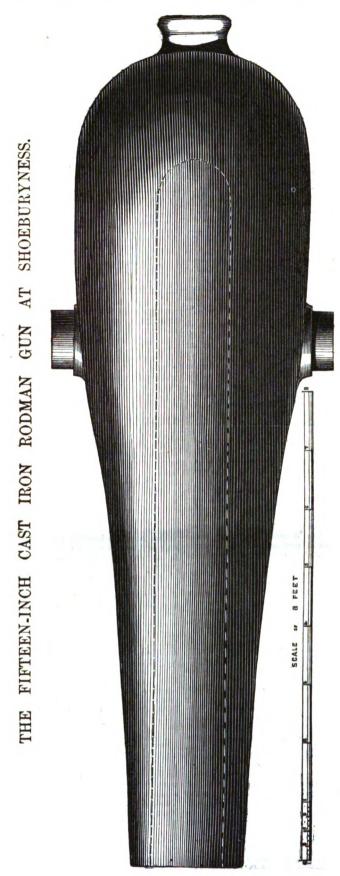

### EMIGRATION TO VICTORIA, AUSTRALIA

WE are glad to learn that the Government of Victorie is taking initiatory measures for the carrying out of emigration on a much more speedy, extensive, and comfortable plan than has hitherto been tried by ocean steamships of large size, registering not less than 2,500 tons, in which the accommodation and general management shall be far in been tried by eccen steamsnips of large size, registering not less than 2,500 tons, in which the accommodation and general management shall be far in advance of that in sailing ships. If the grand problem of bridging the distance between England and Australia in much less time, and at reasonable expense, can be accomplished, the disfavour with which Australia has been more or less viewed, when compared with Canada and the United States, will in a great measure be overcome, and will in all compared with Canada and the United States, will in a great measure be overcome, and will in all probability tend to a very large increase of emigration from Great Britain. In the settlement and opening up of a new country, great inconveniences are always found in the difficulty of communication between the town and country districts. This has to a great extent been overcome in Victoria, by the formation extent been overcome in victoria, by the formation of railways; existing lines will in process of time be largely supplemented by others, and we understand that tenders will soon be invited both in England and the Colony for railway works of considerable magnitude, from Melbourne to Belvoir on the River Murray, the estimated cost of which will be £2,100,000. To artizens and working men about emigrating, we have good authority for stating that ample employment may be looked for, for some long time to come, in the Colomy of Victoria.

### LAUNCE OF A CORVETTE FOR JAPAN.

ON the 77th ult. there was launched from the yard of Messwa. Hall Abordes Messes. Hall, Aberdeen, a large steam corvette, an order from the Japanese Government. The vessel is sane specimen of workmanship, and greatly wessel is An especimen of workmanship, and greatly admired for compact strength and beauty of outline. The corvette, which was christened the "Ibo-Sho-Mara" (the Whirlwind), is of 1,500 tons register, with engines of 250-horse power, measures 210ft. keel, 28ft. beam, and has a depth of 29ft. from the mapper and 21ft. from the main deck. The "Iho-Sho-Mara" is to carry ten guns of large calibre, and is constructed after the model of a first-class British. man-of-war. The vessel is built of British oak and teak; will be full ship rigged, and is intended to sail under steam and canvas combined, or either singly. The upper deck is laid on iron diagonals for lightness, while between wind and water for a depth of 4½ ft. the corvette is to be iron-plated 4½ in. thick, this shield being backed by 6in. of teak. The corvette, which is to be commanded in the first place by Captain James and Lieutenant Inglebach, has been built at an expense of some £65,000.

THE RODMAN GUN.

SINCE the appearance of our article on "American Ordnance," which appeared in the MECHANICS' MAGAZINE, of the 25th ult., a desire has been expressed that we should give a description of the Rodman Gun at Shooburyness. We therefore annex a sealed engraving to which the following particulars refer. The dimensions of the gun are:—Extreme length, 176in, or 14ft. 8in.; length of bore, 12ft. 2in.: greatest diameter at breech, 48in.; minimum at muzzle, 23 in. Weight of solid shot, 450 lb. The ordinary service charge is 35 lb. of powder, and 50 lb. charges may be used

occasionally at long ranges, The official instructions issued to captains of ships state that when attacking ironclads 60 lb. charges may be used for not more than twenty rounds. Licutenant Rodman's system of casting guns consists simply in passing a stream of water through the core in order that the interior of the gun may be cooled as fast, or a little faster, than tee outside, and so initial strains are prevented. The core is an iron tube coated with loam. The quantity of water passed through in casting an 8in. gun is about ten gallons per minute for a period of twenty hours. After melting, the iron is usually allowed to remain for some time in a state of fusion; air furnaces are

almost always used. The cast iron is of great excellence, the test of tensile strength prescribed by the Government is 30,000 lb. per square inch, a variation of 2500 lb. each way being allowed. The proof of the smaller guns is, that one gun taken at random from the whole order shall stand 1000 rounds with service charges, guns 13in. bore and up must stand 500 rounds; but although this seems a severe test, it must be borne in mind that the service charge is small, only 35 lb., and English artillerists generally maintain taat American powder is weaker than ours, which is certainly stronger than any used by continental nations.

ON THE METHODS EMPLOYED IN DE-TERMINING THE COMMERCIAL VALUE AND THE PURITY OF COAL GAS.

BY MR. F. W. HARTLEY. (Concluded from page 264.)

Sulphuretted Hydrogen and Ammonia.

In the Metropolis Gas Act of 1860, it was enacted that the "gas shall, with respect to its purity, be so far free from ammonia and sulphuretted hydrogen that it shall not discolour either turmeric paper or paper imbued with acetate or carbonate of lead, when those tests are exposed to a current of gas issuing for one minute under a pressure of 5-10ths of an inch of water." In respect to these tests, it will be sufficient to say that their efficiency depends upon the delicacy of the test papers. Those used by gas analysts and by gas companies are of the best kind. It is quite certain that a good turmeric paper can be rarely exposed, for a few seconds only, to a current of coal gas without becoming somewhat discoloured, a circumstance which should excite little surprise when it is remembered how difficultit is to free gas entirely from ammonia, and that so small a quantity as one grain in 100 cubic feet of gas is said to be sufficient to affect a turmeric test. The gas referees say that the gas shall be considered impure, rendering the company issuing it liable to the penalties described in the Act of 1868 when it contains more than 5 grains of ammonia per 100 cubic feet, or when it contains the least trace of sulphuretted hydrogen, and they have directed that all the gas consumed in testing for illuminating power shall be passed through an apparatus in which slips of bibulous paper, impregnated with acetate of lead, are suspended in a damp state. As the author understands the instructions, the exposure of the papers would be for about three hours; the test for sulphuretted hydrogen would therefore be very efficient.

In respect to ammonia, the test is to be a continuous one during a period of nearly twenty-four hours. Two test solutions are to be used, one of dilute sulphuric acid of such strength that ten measures of it will neutralize one grain of ammonia. The other of a solution of ammonia, 100 measures to contain one grain of ammonia. The mode of testing is as follows:—Two glass cylinders, of about 1 in. diameter, are filled with pieces of broken glass or with glass beads. A quantity of ammonia likely to be in the gas, is taken, and one-half is poured into each cylinder. The cylinders are then connected together, and gas is passed through both at the rate of not less than 75 of a cubic foot per hour. The ammonia will be arrested by the acid, and a quantity of the acid will be neutralized. The gas is measured by a wet meter after it has passed through the cylinders, in order to avoid the possible absorption of ammonia by the water in the meter. The gas then passes on to the sulphur test hereinafter described.

At the end of about the twenty-third hour thegas current is stoured. The cylinders are well.

At the end of about the twenty-third hour the gas current is stopped. The cylinders are well washed out with distilled water, and the washings collected in a glass vessel. One-half is put into a labelled bottle and set aside for a week. One-fifth of the remaining portion is taken, and a few drops of the solution of hematine added to give a brown colour. A graduated alkalimeter or burette is filled with test ammonia solution, which is dropped slowly into the portion of fluid to be tested until the colour of the mixture changes to pink, the admixture of the liquids being facilitated by stirring. The quantity of acid unacted upon by the ammonia is thus found. At the rate of '75 of a cubic foot per hour, the quantity passed in twenty-three hours will be 17.25 cubic feet, and as the gas is to contain no more than 5 grains per 100 cubic feet, the maximum quantity for 17.25 cubic feet should be no more than 8625 parts of a grain. Ten parts of acid will neutralize 1 grain of ammonia, and there

fore 20 parts of acid would be amply in excess. If 20 parts of acid be used, the whole of the washings be operated upon, and it be found that 135 parts of the alkaline solution (100 parts of which contain 1 grain of ammonia) be required to complete the neutralization of the solid it would be shown that 65 parts. tion of the acid, it would be shown that 65 parts of a grain of ammonia had been absorbed from the of a grain of ammonia had been absorbed from the gas by the acid, and the quantity of ammonia in 100 cubic feet of gas would be 3.188 grains:—17.25 : 100 : : .65 : 3.188.

As, by the instructions, one-tenth part only of the washings is operated upon, the quantity of ammonia solution actually employed to give a similar result would be only 13.5 parts.

Sulphur .- Coal gas, however carefully purified according to the present known methods, contains bisulphide of carbon, and possibly some other compounds of sulphur, whose composition is uncertain or unknown. The determination of the quantity of sulphur contained in purified gas is surrounded with difficulty and uncertainty. It is not found practicable to determine the percentage of sulphur impurities by any direct analytical process. The first part of the usual method of analysis consists in burning the gas, the resulting products being carefully collected. During the combustion of coal gas, sulphuric and sulphurous acids are produced, and the latter acid, there is no doubt, in by far the largest quantity.

The great difficulty in the way of quantitative analysis lies in oxidizing the sulphurous acid into sulphuric acid, and some uncertainty exists as to the extent to which the result of the analysis may be depended upon, owing to the absence of any positive knowledge whether the oxidizing of the positive knowledge whether the oxidizing of the sulphurous acid has been complete, or to what extent it has been partially effected. The first sulphur test was produced by the late Mr. Alexander Wright in the year 1851. It consisted of a Liebig's condenser in which a small jet of gas was burned, the air with which the jet was supplied being charged continuously with vapour of ammonia. The products of combustion—carbonic acid, sulphurous and sulphuric acids—together with ammonia vapour, nitrogen, and an excess of with ammonia vapour, nitrogen, and an excess of air passed through the instrument; and it was supposed that the sulphur acids were completely arrested, and, in combination with ammonia, thrown down with the condensed water resulting

from the burning gas. This instrument was first used with a stream of ice-cold water passing through the condenser, the maximum condensation being thus effected; but it was found, after an extended experience, that the largest quantity of sulphur was never exhibited when the largest quantity of condensed water was obtained. The question of sulphur in gas was not then considered so important as it is at the present time, and no extended experiments were made to fix the conditions under which the greatest quantity of sulphur could be made apparent. It may be supposed that, when the Act of 1860 was passed, and the degree of sulphur impurities was fixed at 20 grains per 100 cubic feet, the opinion was that Wright's and similar tests afforded, as they were then used, the means of arriving at the total quantity of sulphur in gas; such opinion was erroneous. The testing process such opinion was erroneous. The testing process for sulphur became more refined, and gas com-panies have had to struggle most carnestly, and under grave difficulties, to meet the conditions imposed. Fortunately, their efforts have been tolerably successful, although, doubtless, the cost for purification has been largely increased.

Dr. Letheby produced his sulphur test in 1853. or 1854. It consists, as now made, of a cylindrical glass condenser, with hemispherical ends, each end having an open neck, 2in. diameter and 2in. long. The condenser is 4 in. diameter and 13in. long, and is raised by a stand about 20in. above a table or shelf. A trumpet-shaped glass tube, 3in. wide at the base and 3in. wide at the top, where it is bent at a right angle, is fitted, by means of a sound cork, into one of the necks of the cylinder, and hangs with the wide end downwards. Fin. diameter, and about 4ft. long, is fitted with a cork into the other neck of the cylinder, and a cork into the other neck of the cylinder, and projects upwards. A Leslie argand gas-burner is placed below the trumpet, and below that a bottle containing a quantity of the strongest liquor ammonia. This bottle is covered by an inverted glass funnel, fitted with a tin tube, which passes upwards, through the centre of the burner, to about lin. above the jet-holes, so that the products of combustion carry with them into the condenser a large quantity of ammonia vapour.

When instruments of this kind were first

sent to preserve in each a perfect equality in the dimensions of the various parts. Nor were any precise conditions laid down as to the tem-perature of the operating rooms, the rate of consumption for the gas, &c. It was found, however, that such conditions exercised considerable difference in the results. The same gas burned at the same rate, in instruments of different dimensions, yielded unequal quantities of sulphur in the analysis, and the same effect arises, when gas is burned at different rates, in the same instrument. These variations are due, no doubt, to the different temperatures produced in the cylinder, and the degree to which the sulphurous acid is oxidized and combined with ammonia. It is not probable that with any instrument of this character, the whole of the sulphur in gas will be determined, but this is of stilphur in gas will be determined that if uni-little consequence in a commercial test, if unipurified to the highest degree which chemistry, combined with practical experience, show to be possible, it matters little whether the test exhibits the whole or part only of the impurity, providing the test be reliable and uniform in its indications.

The gas referees have resolved that Dr. Letheby's apparatus shall be used. At present they fix no standard for sulphur impurity, but simply direct that tests shall be made and recorded, with a view, it may be supposed, to establish data on which to found a standard of purity. The gas is to be tested in a room where no gas is burned other than that which is being tested for sulphur and ammonia, and to secure greater accuracy, two sets of apparatus are to be used simultaneously, the average of the results so obtained is to be held to show the amount of sulphur contained in the gas. The gas is to be burned at the rate of 75 of a cubic foot per hour during a period of nearly twenty-four hours, when the combus-tion is to be stopped simultaneously in both sets of apparatus, the condensers emptied, and they and the tubes well washed with distilled water, the washings being added to the con-densed liquor from the condenser. The two sets of apparatus are then to be immediately put to work again.

The further operations with the condensed liquor and the washings from each apparatus are as follows, and are practically the same as have been adopted for some years past:—One half of the liquid is put into a labelled bottle and set aside for a week, in case it is necessary to repeat the analysis. The other half is boiled in a glass vessel for ten minutes, and is then treated with an excess of muriatic acid. An excess of a solution of chloride of barium is next added, and the solution again boiled for half an hour. When cold, the liquor is filtered, and the sulphate of baryta When cold which has been formed is collected on the filter paper. This is next well washed with boiling distilled water, to free it from muriate of ammonia or baryta. Sufficient washing is evidenced when a little of the liquor from the filter taken in a test tube remains clear on the addition of a drop of a solution in distilled water of nitrate of silver.

The filter paper and its contents are carefully dried and then placed in a platinum crucible and burned over a Bunsen burner to a white ash. 117 parts sulphate of baryta contain 16 parts of sulphur, and, therefore, if 27 grains of sulphate result from the combustion of 18 cubic feet of gas, the quan-tity of sulphur due to 100 cubic feet would be 20.5 grains, for 18:100::27:150, and 117:16::150:20.5. The volume of the gas used in testing for ammonia and sulphur is also to be corrected for temperature and barometric pressure, the temperature and pressure being noted at the commencement and at the end of an experiment, and the mean being taken.

The foregoing completes the exposition of methods by which the commercial value and purity of gas is determined, and the author believes that there is no country in the world in which gas is subject to such rigid supervision and severe analysis as in England. If consumers only realized this, it is possible that, instead of so often finding fault in respect to deficiency of light, sootiness of gas, &c., they would turn to their burners and fittings in the expectation that they would there find the causes of dissatisfaction. Competent gasfitters should be contracted with to look after burners and fittings in the same way that makers of measures are to look after scales and weights, &c.

The author then referred to the imperfections When instruments of this kind were first which had been mentioned as belonging to the made, the same care was not taken as at pre- present system of gas testing, and spoke of the

jet photometer, which had been proposed as a measurer of illuminating power. It was described as a delicate mechanical pressure gauge, capable of indicating to the 100th of an inch water pressure, to which was attached a steatite jet. gas was burned from the jet at a constant pressure, and the value of the instrument depended on a thoroughly established fact, viz., that the length of a jet flame burning under a constant pressure, varied with the quality of the gas. He admitted the correctness of the principle and the value of the instrument to gas makers, but on several grounds objected to the jet photometer as a measurer of the commercial value of gas. cations would have no significance to the public, while the present system of photometry is quite significant, whether the standard of light be a candle or a lamp. He next mentioned Mr. Valentin's sulphur test, with which there were good reasons to suppose that all the sulphur in gas converted into sulphuric acid. It consisted of a tube of platinum, charged partly with spongy platinum and partly with soda lime; this tube was made and kept red hot in a gas combustion furnace, while gas and air in due proportion to ensure complete combustion (which was evidenced by two circumstances) were drawn through. The mixture passed first through the spongy platinum, and the gas was completely burned; the products then passed through the soda lime, which com-pletely absorbed the sulphuric acid. When sufficient gas for an experiment had been burned, the soda lime was removed from the tube, and dissolved in dilute hydrochloric acid. The after processes were similar to those already described under sulphur analysis. The only objections to this sulphur test were the necessity for using an aspirator and

for increased delicacy in manipulation.

The author next described the analytical processes practised by gas makers, which comprise the employment of the apparatus described in the foregoing part of the paper, of specific gravity tests, and of the endiometer, by which last the amount of sulphuretted hydrogen and of carbonic acid in crude gas, and the amount of carbonic acid, carbonic oxide and hydrocarbons (or lightgiving compounds), in purified gas, is in each case determined.

We would direct attention to the following errata which crept into our notice of Mr Hartley's paper last week. At page 263, under the head of "Batwing Burners," the width of slit of No. 7 should be '013in., not '313in. On the same page, last paragraph on third column, six lines down, read, "The candles are next lighted, with special precautions to preserve the wick well formed. They are, &c.

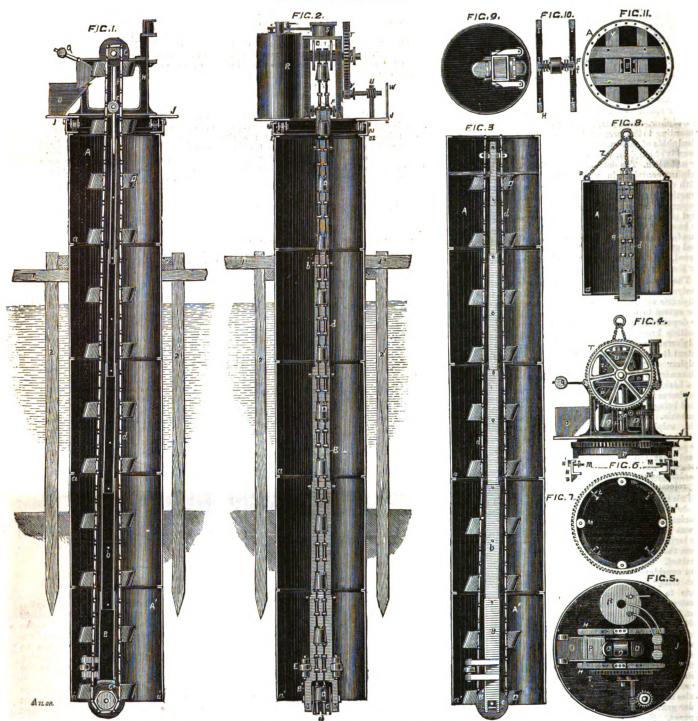

### THE ROTATORY DREDGER.

THE extensive use now made of cast-iron cylinders filled with converte to the converte of the of piers of bridges, &c., is every day adding to the importance of the subject of economical and expeditious modes of sinking them. There can be no doubt that if they could be sunk by excavating the interior with a similar dispatch to, and at the same cost as, ordinary dredging, that plan would be almost invariably adopted in subaqueous foundations where sand or clay has to be penetrated. The method usually employed is to convert the cylinder or caisson into a huge diving bell, with air locks for passing workmen and material from the bottom, where the excavation is effected by manual labour. The process, however, is tedious in the extreme, something like 5ft. or 6ft. deep per day, and the plant required is of a complex and costly character. Other experiments have been tried with more or less success where sand only has to be removed, but where either stones or tree roots, or even stiff material, have to be dug out, they have mostly failed. For this purpose there is no machinery more effective than dredging buckets, which do all that pick and shovel are capable of doing, and at a wonderfully reduced They have, as yet, however, been applied to a very limited extent to the sinking of cylinders, and with only a partial success, attributable to the inadequate state and defective arrangement of the apparatus usually improvised for this purpose. The machinery being carried on fixed staging independently of the cylinder, requires to be con-tinually lengthened while the sinking is proceed-ing, and, being fixed in one position, does not remove stones or other obstructions which it cannot reach. A hole is made in the centre, producing an occasional avalanche of sand which blocks up or breaks the machinery.

To overcome all the drawbacks we have enumer-

### ROTATORY DREDGING MACHINE.

BY MR. DAVID ELDER.

ated, and to meet the requirements of the case, Mr. David Elder, of Newcastle-on-Tyne, has recently designed and patented the rotatory dredger which forms the subject of the accompanying engraving. This arrangement consists of a portable steam rotatory dredger, which is placed on top of the cylinder to be sunk, with a telescopic ladder to facilitate lengthening the bucket chain when a length of cylinder has to be added. The buckets dig from the circumference to the centre all round, effectually removing every obstacle to the descent from the cutting edge of the cylinder. Six-horse power, raising 10 cubic feet per minute, would sink ordinary cylinders at the rate of 10ft. deep per hour. Dredging on a large scale costs 1\frac{3}{4}d. per ton. For this purpose it should not exceed 6d. or some merely nominal sum as compared with the ordinary cost of such operations. The time required has hitherto been a much more serious obstacle to the general adoption of concreted cast-iron cylinders for the foundations of bridge piers, and especially of river walls, than the mere cost of sinking them, and it is chiefly in the saving of time that Mr. Elder's apparatus appears to such advantage.

In our engraving, fig. 1 is a sectional elevation of a foundation cylinder A, bucket ladder B, tumblers C C 1, turntable J, and shoots P and O (one side frame of the machine being removed for the purpose of showing the buckets D, &c.) The cylinders A are furnished with an internal flange a at each end for forming the joints, and which are further utilized for carrying or fixing the machine at the top and for carrying extra loads in the form of annular segments of iron, which may be necessary to impose to effect the sinking operation. The lowest cylinder A 1 has a cutting edge a 1 at bottom. The bucket ladder B is formed in lengths corresponding to those of the cylinder, and is rectangular in cross section for the purpose of taking the torsion strain off the junction pins, and the lengths are made to fit into each other internally and externally or telescopically, so as to enable them to be jointed together at the required length. They are united by pins or bolts passing through holes at convenient intervals for adjusting the length. The lower end of the bucket ladder  $\{i\}$  is bifurcated in form, as shown at B 1 in fig. 2, for carrying the two bearings of lower tumbler C 1; it has also east or fitted on it double bearings

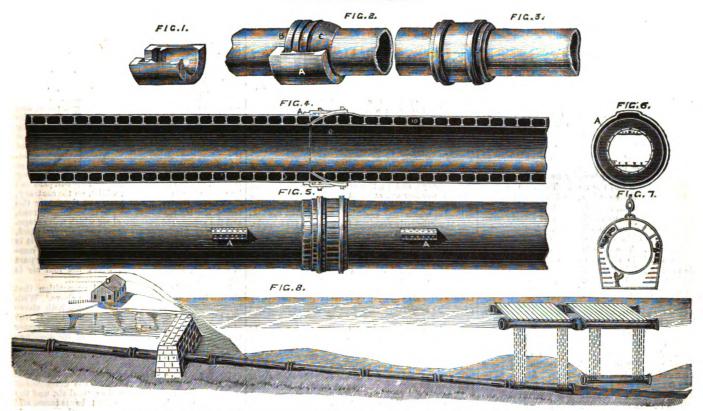

e for carrying the guide rollers E. The upper end of the bucket ladder is formed with an eye, through which is passed the crosshead F. The crosshead is guided in slots f in the side frames of the machine, and is free to rise and fall; the crosshead and eye piece is removed with the machine when the ladder has to be lengthened; it is made to fit the various widths of ladder by introducing suitable slips of iron.

is made to fit the various widths of ladder by introducing suitable slips of iron.

The tumblers C C ¹, buckets D, and links d, are of the ordinary construction. The upper tumbler shaft c has two barrels G G ¹, formed on it, recessed for receiving pitch chains for hoisting the ladder, &c. It is carried on the side frames H of the machine, and driven by a disengaging clutch J, as shown in fig. 2. The side frames H are fitted and bolted to an annular sole plate J, and carry the engine and bearings of the gearing. The sole plate has two annular feathers K K which carry the perpendicular bearing rollers L and the horizontal guide rollers M. These rollers bear upon the internal bottom flange m and side of the foundation plate N, sustaining the weight and guiding the rotation of the machine. The foundation plate N is formed to fit the top of the cylinder

#### TUBE JOINT A N DSUBMARINE TUNNEL.

BY MR. C. MARSDEN.

**A, and** is fixed temporarily on the top flange a of the cylinder. It is furnished with guide brackets the cylinder. It is furnished with guide brackets n on the bottom to facilitate the placing on the cylinder, and a toothed circumference N 1 on the top for the turning gear. It has also an internal flange n 1 on the top, so as to be lifted with the machine by the guide rollers L or horizontal pins l, projecting for the purpose when the machinery is being removed. The delivery shoot O is fixed to sole plate, and is furnished with a door to discharge at intervals. The movable shoot P is hung on a pivot or shaft, allowing it to oscillate, and kept inclined to the bucket chain by counterbalance weights Q, so as to save the material raised, and allow it to yield to the pressure of the buckets and allow it to yield to the pressure of the buckets when passing.

Fig. 2 is a sectional elevation at right angles

Fig. 2 is a sectional elevation at right angles to fig. 1, showing the actuating machinery, consisting of the boiler R, the engine S, the main driving wheel T, and the turning gear U. The turning gear is driven by a disengaging clutch V, and is supported by bearing fixed on side frames H, and sole plate J; a hand rail W surrounds the sole plate. Fig. 3 is an elevation of the bucket ladder B, with the machine removed for the purpose of lengthening the cylinder A. The links are detached, by the withdrawal of the pins at the top and the chain d is secured by being hung to the and the chain d is secured by being hung to the ladder by passing cotters X through holes made in the ladder for that purpose. When the chain is detached, the ladder is allowed to rest on the ground at the bottom, and is kept in position at the top by a temporary platform Y supported by brackets, and bearing on the side of the cylinder; this platform is also utilized for conveniently bolt-

this platform is also utilized for conveniently bolting and making the joints of the cylinder. Fig. 4 is an elevation of the machine as being removed, showing the mode of slinging. The chain slings Z are hooked to eye bolts  $z^1$  in the side frames. Fig. 5 is a plan of the last figure. Fig. 6 is a vertical section of the foundation plate N, showing the toothed surface  $N^1$ , guide rollers M, showing the toothed surface  $N^1$ , guide rollers M, showing the toothed surface  $N^1$ , guide rollers M, showing the toothed surface  $N^1$ , guide rollers M, showing the toothed surface  $N^1$ , guide rollers M, showing the toothed surface  $N^1$ , guide rollers M, showing the state M and lifting showing the toothed surface N 1, guide rollers M, lower flange m, guiding flange n, and lifting flange n. Fig. 7 is a plan of fig. 6, showing guide and bearing rollers M and L, toothed rim to sole plate N 1, bearing flange m, and upper flange n. Fig. 8 is a sectional elevation of a cylinder showing the mode of slinging and of lengthening the bucket ladder and chain. The links d are secured to the ladder B by cotters X and the ladder hooked by the chain Z, the same sling serving for the cylinders and the machine. Fig. 9 is a plan of cylinder A, at cutting edge a 1, showing cross section of lower end of ladder B, buckets D, friction rollers E, bearers e, and links d. Fig. 10 Fig. 8 is a sectional elevation of a cylinder showing the mode of slinging and of lengthening the bucket ladder and chain. The links d are secured to the ladder B by cotters X and the ladder hooked by the chain Z, the same sling serving for the cylinders and the machine. Fig. 9 is a plan of cylinder A, at cutting edge a 1, showing cross section of lower end of ladder B, buckets D, friction rollers E, bearers e, and links d. Fig. 10

is a sectional plan of side frames H, showing cross-head F and guides f. Fig. 11 is a plan of top of cylinder, showing flanges a, cross section of top of ladder B, kept in position by the temporary wooden platform Y.

wooden platform Y.

In operation, the cylinders to be sunk are guided by a frame 1 1¹, and guide piles 2 2¹, in the usual manner, but any bias from the vertical is counteracted by disengaging the turning gear, and digging from one side, the resistance of the ground deflecting the bucket ladder towards the side of the cylinder until it bears on it by the guide rollers E, insures the removal of the earth from the cutting edge a¹ of the lower cylinder A¹, and the rotation completes the entire excavation from the periphery to the centre. Should the buckets meet with any unusual obstruction, the chain raises the ladder until they are free, should the buckets meet with any unusual obstruc-tion, the chain raises the ladder until they are free, or should they get jammed, the ladder can be raised by the hoisting barrels and chains. The engines are fitted with back and forward valve gear, driving the dredging and turning gear either together or separately, and the boiler is supplied with water by a steam pump with suction hose to the water in the interior of the cylinder, or to a tank supplied by the dredging buckets. The cylinders and the machine are lifted off or put in their places by a travelling crane overhead on a fixed staging, in the usual manner, or in tidal waters the lifting and removal may be conveniently done from an overhanging stage on a floating barge similar to what is ordinarily used for diving bells, which need only be of sufficient height to put on a cylinder at low water and the machine at

high water.
When the apparatus is applied to raising earth vertically from shafts, wells, and other similar excavations, the turntable with the machine and apparatus is placed over the proposed excavation, and the work proceeds in a similar manner to that previously described for sinking cylinders. When the dredger is employed for raising earth for docks, canals, cuts, and similar excavations, the upper end of the ladder is attached to a turntable to enable the machine to turn to accommodate the horizontal angle of the ladder. The turntable is on a truck placed on a railway laid alongside the

machine. When not under water, the suspending chains are fixed similarly to the mooring chains The truck may also be made to travel on its rails by driving the wheels as in a travelling crane, or by heaving on a mooring chain. In order to strengthen the beam or ladder, Mr. Elder sometimes applies a truss on the under side. The buckets are discharged into waggons placed on a railway. The buckets, links, ladder, and turn-tables are all of the ordinary construction, but the apparatus is carried on a platform carrying also the engine and boiler, driving and hoisting gear, fixed on a turntable similar to the apparatus described for sinking cylinders. The apparatus is not required to rotate completely, but move in an arc sufficient to accommodate the ladder to the slope of the work.

#### MARSDEN'S TUBE JOINT AND TUNNEL SCHEME.

IN the annexed engraving we illustrate a very important improvement in making the joints of gas or water pipes tight, and at the same time flexible. It is the patented invention of Mr. Charles Marsden, of 224, Kingsland-road, London, who has also worked out a scheme for connecting England and France, by means of a tunnel, jointed on his principle. We will first describe the simple pipe joint, as illustrated in figs. 1, 2, and 3 of our engraving, and afterwards proceed to notice the proposed tunnel. Mr. Marsden's plan is to have a flange on one end of each length of pipe, upon which circular projections are formed. The opposite end of each length is also made with a bulge or protuberance on the exterior, which has bulge or protuberance on the exterior, which has circular projections, similar to those on the other end. The spaces between the projections are filled in with packing, and the ends of the pipes are brought together, the end of one just fitting into that of the other. The ends are then connected, by being enclosed within a ring or socket, formed by the context which are formed about the context of the contex in two parts, which are firmly held together by rings and screws. The inner edge of the end of one pipe is chamfered, and the outer edge of the end of the other is made to fit inside the chamfer, so that a ball and socket action is secured, and the pipes will follow any undulation caused by a settlement of the ground in which they are laid. Fig. 1 represents a half socket, which is seen in place at A, fig. 2. In the latter figure, B is the flange with the furrow to receive the packing, C being the circular projection or ball, with a similar furrow. Fig. 3 shows the joint completed by the addition of the outer rings.

Turning to the tunnel scheme, we have the same principle, differently carried out in detail, to meet the requirements of the case. This principle is also that which Mr. Marsden adopts for pipes of large diameter. It consists in fitting one end of the pipe with a series of stepped or curved plates, which are secured in place by sorows or rivele The adjoining end of the next pipe is fitted with a bulge or socket. Another series of plates is employed, one end of which is forced under the open end of the stepped plates. They are plates vented from falling out, by being guided into position by a number of rings, fitted on the end of the pipe. Another ring is employed on the outside, to hold the places. A portion of this ring is looped or predicted, to enable the place of Be placed in position. When passed the place is position, when passed the place is successive, so as to meet each other, until the whole diameter of the print end is covered. They are then firmly sectioned in place, by keys being driven in between them said the ring. The loop is then filled in with a wedge piece, and thus the whole joint is made sound, flexible, and tights.

The method of construction will be alearly seen Another ring is employed on the outside,

The method of construction will be clearly se from our engravings, in which fig. 4 is a scotlonal view of the ends of two lengths of sales showing the joint. The tube is built of scotle sales, and has a double skin, on the well-known state, and has a double skin, on the well-known state, and has a double skin, on the well-known state, and has a double skin, on the well-known state, and has a double skin, on the well-known state, and the sales should be sal rilled in with artificial stone. Fig. 5 is an exterior view of the joint, with the plates and rings in position. Fig. 6 is an end view of the tunnel, constructed with joints, as in figs. 4 and 5. In this view, it is seen how Mr. Manadem proposes to carry pipes for ventilating the tunnel, as well as pipes for water, sewage, and telegraph wires, at the top of the tunnel. At the bottom runs the line of road, on which the railway is laid. The ventilating pipes are formed with longitudinal slots. Air is to be forced from the short and into these tubes, which will pass through the stoke into the tumiel, and ventilate it. In this figure, A is the clip ring to which we have already made reference. Bracings are provided at A, fig. 5, which are to receive the blocks and falls for lowering the lengths of tubing into position in constructing the tunnel. Fig. 7 is a credle for the divers to work in, when making good the joints of the tubes, which are to be caulted with asphalte. Fig. 8 shows generally the method of laying the proposed tunnel according to Mr. Marsden's design, and which we shall near proceed to describe.

A cutting is first to be made on land about two or three miles in length, gradually descending to a point where the water is about 10 fathoms deep. A see wall is to be built about 50ft, from the wa euge. A portion of a cylinder is to be built in the wall and made watertight, and the sea is then to be allowed to flow up to the wall, so that the next cylinder can be floated and placed in a proper line. The same with the next and so an allowed. edge. A portion of a cylinder is to be built in the he same with the next, and so on, lo from a raft which they will form. Mr. Marsden proposes that divers should cut through moderately high projections in the Channel bed, and also the levels, making a trough, into which would be lowered clay, the divers puddling the same, and thus forming d for tubes to rest upon. The cylinders can b made on the coast, and, when finished, have their ends stopped, and be towed to the spot required, with the artificial stone composition. Four or six of the tubes can be used to form a raft or stage to carry the machinery for lowering and fixing the tubes in place, and afterwards can be used on the land end to finish the connection on shore. By this means, Mr. Marsden estimates a working tunnel could be completed in about four years, without the danger of its being flooded.

The heading at each end is to be made in three

or more parts, and well secured with india-rubber, or other packing, and screw bolts. The heading after two or three cylinders are fixed together from the outside, is to be removed from the inside, making an entrance from the shore end into the next tabe and so on throughout. The double cylinder is braced to keep the inner from the dusty. The praced to keep the inner from the outer. The space between the two, which is bit. of fill, is to be filled with tarred granite and asphalts, which will form a perfect wall. As Mr. Marsden considers it impossible to have a ventilating shart in the Channel, he proposes to have machinery on each shore to abstract the vapours from, and also to force air into, the tunnel. Mr. Marsden's estimate for a tunnel between England and France on his principle is £12,260,000.

FAIR supplies of new potations have their London from Scilly within the last few days.

ON VENTILATION.\* By Dr. Edward Smith, F.R.S. PART II .- MODES OF VENTILATION. (Continued from page 244.)

(Continued from page 244.)

(UCH is a short reference to some of the more in ordinary and important principles involved, and I now protect to offer a few observations of enthing methods of ventilation. The ordinary method, every thing from the first of the protection of the degree is which there are expensive.

The objections to this plan are:

1. The attention of some person is required to regulate the openings according to the degree of ventilation required; and as this cannot be the chief

regulate the openings according to the degree of ventilation required; and as this cannot be the chief duty of a particular person, whether is a private of a particular person, whether is a private of a particular person for the duty with a particular knowledge and particulars; the result is either too fittle of too much remiliation.

2. In the summer time, when ventilation is required but fire is not weated, it is very usual to close up the chimneys, and particularly those of bedrooms. In cold weather and at night all doors and windows In cold weather and at night all doors and windows are closed, and they act as ventilators only in the degree in which they are ill-fitting, whilst ventilation is particularly required in bedrooms at night, and the use of gas in the long winter evenings calls for good weatherness in sitting rooms.

Such as a requirement chance by otherwise that discourse, jet it has not been objected to even in some hospitals, for during a late discourse on this subject it was gravely affirmed that the ventilation in workhouses must be defective, because workhouses

in workhouses must be defective, because workhouse nurses were said to be less reliable than those of a particular hospital in reference to the opening and

closing of the windows. Many devices have been adopted with a view to ventilate by windows. Some have the double-hung sashes by which air may be admitted at the highest sashes by which air may be admitted at the highest and lowest parts, and in a degree in the middle ateo, in such proportion as may be desired, and the believe, the best construction at present known; provided the window extends so near to the ceiling that, when the upper sash is drawn down but a little, the entering air may be so far above the bed, or above the head of the immates, that the current may not be injurious. It is, therefore, inapplicable as the sole means of daily ventilation to low rooms, viz., to rooms less than 10ft. in height. Some windows have the upper portion to fall inwards, with a view to direct the current of air upwards, and it is held in that position by a cord, or by falling into a hopper with the sides of the V-shaped space closed or open. Such a ventilator admits too large a volume of air in one place in cold weather, and in order that it may Such a ventilator admits too large a volume of air in one place in cold weather, and in order that it may be safely used, the room must be of great height, as, for example, 14ft, and upwards, but even then it causes discomfort, since the current of cold air eventually falls, and the room becomes cold, unless other meens of warmth are provided than open fireplaces. I have, however, seen this plan in operation in windows within 3ft of the head of the sleeper, but windows within 570. Of the head of the sleeper, but in such places the natural remedy was applied, vis., to shut them, except when kept open in the presence of superior authority. Others have the lower half of the window to fall forward into a hopper, and the evils just mentioned are intensified; whilst a more modern, but scarcely better, invention divides the window into four of more parts, each or all of which may be opened at pleasure, and fails for the like

A very frequent contrivance in the old iron window frames is to provide a special portion in the centre or upper part of the window which may be opened inwards, outwards, or laterally, or fall inwards into a hopper. Such openings are always placed too far below the ceiling, but the quantity of air admitted in one place is smaller than where the opening extends across the whole sash, and they are only so far less injurious. The old lattice window, which opens by hinges on its side, is in like miniter unfitted for the purpose of ventilation, except in conditions where a large volume of air could be silmitted without injury. A very frequent contrivance in the old iron window

without injury.
These evils having been appreciated, ventilation has been effected by placing perforated zinc or perforated glass panes in some parts of the windows, or a strip of perforated zinc has been placed across the

rated glass panes in some parts of the windows, or a strip of perforated zinc has been placed across the top of the window frame, to act when the upper sach its drawn down, and where the windows have been high, and the ventilisting panes have occupied the highest cityation, the plan has from very virtuable, and the ventilisting panes have occupied the highest cityation, the plan has from very virtuable, which the principle is that of a ventilistor, said not of a windows properly so called, are forther in the ceiling, and companies of vertical air wherever placed, and with the ventilistors properly so called, are forther in the ceiling, and companies of vertical with the ceiling, and companies of vertical with the ceiling, and companies of vertical with the external air by external gratings, with or without special channels, or simply by the stockential openings in the roof. The principle involved in their use is that the foul air ascends, and stockential openings in the roof. The principle involved in their use is that the foul air ascends, and stockential openings in the roof. The principle involved in their use is that the foul air ascends, and stockential openings in the roof. The principle involved in their use is that the foul air ascends, and stockential the control of the vertical openings, and when not defended they will admit all all the control of the wind. When not defended in the stockential within the found whether are in proportion to the size of the opening and the found with the control of the wind. When not defended in the first and direction of the wind. When not defended in the first and direction of the wind. When not defended in the first and direction of the wind. When not defended in the first and direction of the wind. When not defended in the first and direction of the wind. When not defended in the first wind direction of the wind. When not defended in the first wind direction of the wind. When not defended in the first wind direction of the wind. When not defended in the first wind di

stove or firegrate, or by hot water pipes, the air may be heated, but is not foul. But assuming that the air is both heated and vitiated, it does not follow that the foul air will ascend to the top of the room, air is both heated and vitiated, it does not follow that the foul air will ascend to the top of the room, since certain noxious matters, as carbonic acid (the chief product of respiration), are heavier than air, and with a still atmosphere, and the source of vitiation at the height of a man or of a bed only, will, in a degree, tend to accumulate in the lower part of the room. The practice is, undoubtedly, correct in reserved from the products of gas burning and to determine from the products of gas burning and to accumulate in the lower part of the room. The practice is, undoubtedly, correct in reserved from the products of gas burning and foul air are leasted to the generated heat and foul air are leasted to the generated heat and with few persons at night, without gas or fire, and with few persons also ping in a room, it is not applicable. In such conditions it is true that the heat is generated, and the least the heat is generated, and the least the degree of the whole of the exceeds, and further ascent is retained or prevented. The highest the room, and the less the degree of heat generated, the weaker will be the seconding current, and the less the cultury of air will puss out by ventilators in the ceiling, whilst, on the contrary the greater the supply of heat, and the lower the room, the stronger will be the ascending current, and the greater the quantity of air which will escape. the greater the supply or heat, and the lower the room, the stronger will be the according current, and the greater the quantity of air which will escape. Hence its operation is not equal and universit; and, from the story strains that it is will be seen that it is a party impubilists to residue the facts, in the conjugate with a residue of operating in the large part of the room, that is to say, where the four air is generated.

generated.

Further, it is not an universal proposition that air will be admitted below and escape above. With little increase of heat it will be admitted both above and below, and with much increase of heat it will escape both shove and below, although in greater amount above than below. Some of the openings so wasted in the below. Some of the openings so wasted in the control of the control desired those the size of the tube, the difference of temperature of the internal and external air, and the force of the wind, but where the tube is large, and the generation of heat is not great, the current is usually inwards. Some such ventilators have the tube divided by a perpendicular diaphragm, which, in fact, makes the one tube into two, and is stated that the air ascends by one and it descends by the other. Whether it will ascend by either depends upon the amount of heat generated within the room, but even where the latter is very great, and there is upon the amount of heat generated within the room, but even where the latter is very great, and there is a strong current upwards, it will be found that there is an ascending and descending current in both tubes—currents not of equal force or volume, but varying with the admission of air by other openings, as I observed when instituting inquiries into the sanitary state of printing houses and workshops for the Privy Council.

The fallacy which lies at the root of these states ments is in ignoring the fact that inhabited more than the property of the sanitary state of printing houses and workshops for the privy Council.

ments is in ignoring the fact that inhabited rooms are not boxes hermetically sealed, or having only are not boxes hermetically sealed, or having only one opening for the admission of air, ignoring the existence of doors and windows, which even when closed allow a certain quantity of air to pass. If the room were a box, closed except at the ventilator, it would follow that if air passed out it would also pass in by the opening; and it may be that under certain conditions of temperature the air would rise in one than the sealer of the passed on the conditions of the passed on the sealer of the passed on the passed conditions of temperature the air would rise in one table and fall in another, but such rooms do not exist. The most frequent approach to this condition is where there are two fireplaces in one room, in one of which a fire is burning, and the doors and windows fit well and are shut, for in such a case that may be a down draught in a chimney without a fire. But even this is not universal, for with the tendency to rarefaction of the air which occurs by reducif of this heated air passing up the chimney, the heated placed at the sides of the door or window will perceive air unusual rush of air inwards to prevent a victoria; and thus prevent the necessity for a down draught. Moreover, where there is only one chimney, and the doors and windows fit closely, the fire languishes, and the more so the longer the doors and languishes, and the more so the longer the doors and windows remain shut from the rarefaction or loss of air

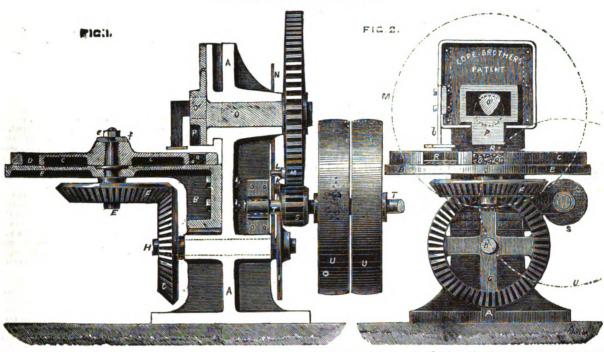

which the heat induces. Open the door or window, and the fire will brighten, and the sense of oppression felt by the inmate will pass away.

It practice it will be best to consider that air will look either said leave by openings communicating with file external air wherever placed, and with the crafficient of doors and windows if air be crafficled to construction of doors and windows if air be crafficled and with the craffic with a whole the deficiency will be immediately supplied, but, in order that heated air may be quickly removed, it is essential that there should lie openings at the upper part of the room.

Other workflators are placed in the moner part of

### TOBACCO PRESS.

BY MESSRS. COPE BROTHERS.

current is from without and downwards. Hence

current is from without and downwards. Hence some defence is needful, and if none be provided, the inmates will, if possible, extemporize one by the aid of rags, clothing, or bricks. The defences are:—

1. Perforated zinc of varying degrees of fineness of perforation—the finer, the more is the current divided and the less it is felt, whilst, at the same time, the greater is the impediment offered to the admission of air, and the less air is admitted in a given time.

given time.

2. A solid, but movable barrier, which may drawn away laterally or vertically, or allowed to fall forward into a kind of hopper, or the ordinary glass or wooden louvre ventilators. Such may be entirely or wooden louvre ventilators. Such may be entirely closed, and then they are no longer ventilators, and when the hopper is open not only is the current directed upwards, but the entrance of air is impeded. Hence, when open, the value of these ventilators varies with the quantity of air which they admit in a given time, and their fitness depends upon their sufficiency, and upon the sensation which the inmates have of the existence of a current.

3. A fixed barrier to the direct entrance of air, placed at a little distance from the external or internal opening. This is sometimes so effective as to nearly

placed at a little distance from the external or internal opening. This is sometimes so effective as to nearly destroy the value of the ventilator by preventing the entrance of air.

4. Different elevations of the external and internal

the entrance of air.

4. Different elevations of the external and internal openings, by which the entering current strikes the wall, or the side of the tube, before it is admitted into the room, and its force is broken. The efficiency of this depends upon the length of the tube and the force of the wind.

A third series of ventilators act by mechanical means, or by an arrangement for the production of heat, and consist of tubes, of various forms, which communicate with the rooms and the external air.

The Archimedean screw is an example of the former, and, being placed at the top of the flue, is moved by a vane, acted upon by the wind. It has been proved that a screw, moved in this manner, carries up a column of air as it would a column of water; but it is dependent for its action upon the wind, and when winds are light, as in summer, and circulation of air is specially required, it fails. When in action its efficiency depends upon the length and diameter of the tube, in relation to its own power, and it is more efficient in the upper than in the lower rooms of a lofty house. It must also be added, that the tube will act as a ventilator, like other tubes, without the screw, and will admit or give exit to air on the principle already laid down.

Special openings into the chimney, as by Arnott's and Toynbee's ventilators—the former of which is liable to allow the smoke to escape—and flues passing by the side of chimneys, are examples of the second series, since their special action as ventilators is due to the warmth of the chimney, by which an ascending current of air is induced. Such flues act in proportion to the temperature of the air within them, and therefore to the heat of the chimney, their proximity to the chimney, their length, and the volume of air which they contain; and it is clear that neither ventilation into chimneys, nor flues placed by the side of a chimney, can produce an upward current where there is not a fire burning,

or where the chimney or special flue is not heated. or where the chimney or special file is not heated. This is very frequently forgotten by architects, and as; fires are not commonly made in bedrooms at any season, nor in any rooms in the summer time, they fail to produce an ascending current. Yet they may not

as in some part of commonly made in bedrooms at any season, nor in any rooms in the summer time, they fail to produce an ascending current. Yet they may not be entirely useless, since air will usually descend by them when it cannot ascend, and they supply air to the room; and as the special flues are less dirty than chimney flues, the air they admit may not be disagreeable to the senses.

To remedy this defect, a jet of gas is sometimes placed within the flue or a reservoir of hot water, or a fire is placed near the upper part of the flue with a view to produce and maintain an ascending current of air. The efficiency of all these methods depends upon the amount of heat applied in relation to the width and height of the flue, and it must not be assumed that because there is a single jet of gas in some part of the flue an ascending current will be always maintained. The efficiency must be tested by experiment. The openings of such flues are sometimes placed at the ceiling, either with one grating or with several, more or less concealed in the cornice which extends around the room; or they are placed at different elevations in the side walls, or on the central line of the floor of the room. One of the more recent inventions of this class is the ventilating gas burner, by which fresh air may be admitted from without, and consumed air emitted by the chimney; but the state of the ceiling shows that, in some instances at least, the whole of the foul air is not removed, and it is too costly for universal use. Another is the ventilating stove, by which fresh air may be admitted from without, and warm air driven through into the room, and both currents may be regulated. This may be adopted without much increase of cost if the stove be introduced when a stove of some kind is needed. Care should be taken to remove the entrance opening of without much increase of cost if the stove be introduced when a stove of some kind is needed. Care should be taken to remove the entrance opening of the warm air so far from the chimney opening that the current may not be directed up the chimney instead of into the room. The forcing or suction pump, or the driving wheel, may also be mentioned; but their use is restricted to large public buildings. They are, however, very effectual in creating a draught, whether by withdrawing or injecting air. All these artificial methods, however, are costly, and nearly all of them are dependent upon conditions which require the aid of man.

(To be continued.)

### MESSRS. COPE'S TOBACCO PRESS.

WE recently noticed the improvements effected W by Messrs. Cope Brothers, of Lord Nelson-street, Liverpool, in tobacco-spinning machinery. We now draw attention to another mechanical We now draw attention to another mechanical arrangement which will prove of value to the manufacturers of cavendish tobacco. This is a press for moulding tobacco, and which is now in use at the Richmond Cavendish Company's bonded works, where sweetened cavendish, similar to the American, is manufactured under Gladstone's Act. In our engraving (for which with particulars we are indebted to the "Tobacco Trade Review") we give

at fig. 1 a side elevation, partially in section, and a fig. 2 a front elevation of this machine. A is a strong framing of cast metal, standing on a solid foundation, having bolted to it B, a circular stationary metal plate. This plate is turned on the top side to a true surface, and formed with an openstrong framing of cast metal, standing on a solid foundation, having bolted to it B, a circular stationary metal plate. This plate is turned on the top side to a true surface, and formed with an opening in it a little to the left to allow the thrust-plate b to push out the formed and pressed tobacco. Upon this plate is mounted the die or movable plate C, which is also circular in form, having near its circumference a number of die-holes D. A shaft E passes through these two plates, and upon it is a wheel F, gearing into the wheel G, on a shaft H, which presses through the framing A, and carries the pawl k and the stud L secured in the driving-wheel, the stud L, comes into contact with the lever N, and moves the die table C, bringing another die D under the die-piece or presser P. A cam-shaft O is fitted into the driving-wheel, and thus actuates the die P, the required stroke for pressing the tobacco, and at the same time pushing out the previously pressed tobacco through the openings in the lower plate B, into a travelling apron. By this arrangement of mechanism it will be seen that the cam O, for a quarter of its diameter, is turned from the same centre of the shaft, so that the slide or diepiece P ceases its motion for a time at the top and bottom of its stroke. The tobacco remains under pressure for a quarter of this revolution. The same takes place at the top of the stroke, thus giving the die-table C sufficient time to move from one die to the other before the die-piece P descends again upon the tobacco Q, in the next die. The tobacco is usually covered over by a thin metal plate R, which fits the die exactly, and keeps the tobacco in position until the die-piece P comes down upon it and presses it to the required thickness, when on the next moye it is pushed out by the thrust-plate b. The full pressure of P is exerted with ordinary shag tobacco for two seconds on each die full. The machine for manufacturing cavendish, rifle-cake, or any other tobaccos of this class. Hitherto manufacturers have had to part

On Saturday week a peal of six bells were cast at Messrs. Blew's foundry, Birmingham, for a church at Yass, near Sydney.

THE RECENT EARTHQUAKE SHOCKS. AT the ordinary meeting of the Manchester Literary and Philosophical Society, held March 23, 1869, the Rev. William Gaskell, M.A., vice-president, in the chair, Mr. E. W. Binney F.R.S., F.G.S., stated that he was sitting in his dining room, Spring Bank, Crumpsall, reading at the time he felt the earthquake on the 15th The height of his house above the sea would be about 240ft., and the drift deposits underlying it consist of 50ft. of sand and about the same thickness of till or brick clay resting on the pebble beds of the trias. His sensation of the shock was as if the bed in the room over him had been drawn from east to west, and immediately afterwards the chair in which he was sitting on the west side of the room moved as if the foundations of the house were giving way. The shock did not last more than a second. The windows in the house rattled, but no one in it beside himself noticed the occur rence, which took place about nine minutes past six p.m. The feeling he experienced at the last, of the foundations of the house appearing to give way, was extraordinary, but the other sensations felt would not have attracted his attention, and he is of opinion, that very few people in the neigh-bourhood of Crumpsall would have known it to have been the shock of an earthquake had they not been told, or seen it described in the newspapers

of the following morning.

He is convinced that the shock would be felt much stronger in those houses which were built upon the pebble beds at Cliff Point, in Lewer Broughton, as was the case of the residence of the President, Dr. Joule; the vibrations of the bare rock being very different there from what they would be where it was covered with 100ft of plastic clay and soft sand, as at Crumpsall. As far as he has been able to learn, the shock appears to have been felt in an east and west direction between Huddersfield and Manchester, and from Stockport to Burnley, along the line of the pennine chain, which forms the high land of Lancashire and Yorkshire.

The tract of land lying between the two great dislocations of the earth's crust in the neighbourhood of Manchester, running nearly parallel to the pennine fault, namely, those of Smedley and Clayton, and the Great Irwell faults, displacements of the strata to the extent of between 3,000 and 4,000ft., would lead us to expect that any disturbance of the earth's surface would be felt with greater intensity between those two great lines of fracture. Now, Smedley Hall and the President's residence at Cliff Point both lie in this tract, and being placed on or near the solid rock, the vibrations would be much more jarring and severe as was, he believed, the case at both places, than where he (Mr. B.) felt them at Crumpsall, on a thick cushion of clay and sand. Mr. Spence stated that he and several members of his family also felt the shock on the 15th ult., at his residence, Smedley New Hall, and that it was accompanied by a loud noise as if a heavy package had fellen on one of the chamber floors

The following communication on the same subject, from Mr. T. T. Wilkinson, F.R.A.S., was road:—A very smart shock of an earthqueke was felt at Burnley on March 15, 1869, at about 6 hours 8min. p.m. I was standing in my room at the time, with my face to the S.E., and was startled by a rumbling sound behind me. It appeared to pass from about N.W. towards the S.E. or almost exactly in the plane of the magnetic meridian. At first I imagined a wall was falling down in the next apartment, but in an instant I was thrown forwards—then came a violent tremor—and lastly a settling back into my original position. The duration of the shock was not more than four or five seconds. On making inquiry I found that many others had experienced similar sensations, and that much alarm had been created by the shock. In some of the mills the looms appeared to be heaved up-doors were displaced-and the more delicate machinery thrown out of gear. House bells were set ringing, and the crockery rattled as if about to fall from the cupboards. The dogs howled as if in alarm—the cannry birds fluttered about in their cages—and several horses refused to move on for some time after the shock. In the higher parts of the town the walls of the houses swayed to and fro, and now exhibit cracks; and the twist split a strong supporting beam in one of the shops in Manchester-road. The stalls in the open market were much shaken, and one of the hucksters ran round his canvas with the intention of catching the youngster who was playing him a trick. So far as I can judge, the magnitude and duration of the shock were very similar to those in the earthquake which passed through this district in July, 1839.

AMERICAN NAVAL BOARD.

A FEW weeks since we particularized the pro-posed formation of a Board of Naval Admini-stration in the United States. The Bill for authorizing this step has passed the Senate. It provides for the creation of a Board of Naval Survey, which is to consist of three officers not below the rank of rear-admiral, who are to have general supervision of all matters relating to the construction and equipment of vessels, the management of navyyards, &c., and make recommendations in regard thereto to the Secretary of the Navy. No promo-tion is to be made to the rank of Reutenantcommander on the active list until the number in that rank is reduced to eight, which is thereafter to be the limit; the number of lieutenants is hereafter to be 280, and the number of masters and ensigns is fixed at 100 in each rank. The number of officers in the medical pay and engineer corpsists to be reduced to specified limits by ceasing to make promotions until the limits are resched. The marine corps is to be constituted as follows:—one brigadier-general commandant, one colonel, one lieutenant-colonel, three majors, one adjutant and inspector, one paymaster, one quartermaster, one assistant quartermaster, fifteen captains, twentyfour first-lieutenants, twenty-four second-lieutenants, one sergeant-major, one quartermaster-ser geant, one drum-major, one principal musician, 150 sergeants, 150 corporals, 130 musicians, drummers, and fifers, and 1,500 privates. The reduction is to be made by ceasing promotions. An additional section provides that the students in the Navad Academy are hereafter to be styled cadet midshipmen. The pay of midshipmen is fixed at 1,000 dollars per annum. The Bill now goes to the House, but it is thought hardly likely that it willness through this Santin pass through this Session.

WEATHER IN AUSTRALIA.

THE thermometer at Melbourne Observatory on January 27 reached 99-5deg, in the shade; at Greenwich Observatory the highest was 46deg, in in the shade, or less than half the amount at Melbourne. The hottest day of the season, however, in Melbourne was the day before Christmas Day. when the thermometer marked the extraordinary height of 110deg. in the shade. Cattle and sheep in when the themometer marked the extraordinary height of 110deg, in the shade. Cattle and sheep in Australia have suffered very severely from want of grass and water. In a Wagga Wagga paper we read that "in almost every direction the roads are swarmed with flocks of wretched animals, mere bags of bones seeking in vain for a mouthful of something, anything, to eat. A flock belonging to Mr. Morton, Grubbengong, had been driven to Bland's Creek, and were brought back to Grubbengong, with a loss of 1,300 from starvation and thirst; 500 were lost at one fell swoop by rushing pell-mell, in the agonies of thirst, into a water-hole, and smothering themselves in the mud." On reference to tables prepared at the Melbourne Observatory, we find that the total rainfall at Melbourne for 1868 was 18-3in., the average for the last ten years being 25-2in. Thus 1868 was deficient in rainfall to the extent of about 7in. The winter season was especially deficient, as 1808 was dencient in rainfall to the extent of about 7 in. The winter season was especially deficient, as in the three months June, July, and August only 3-7 in. of rain fell. The consequence was that the ground failed to be properly saturated at the proper season, and vegetation was thus unable to resist the weather of the summer time. The rain which fell during December was 1.2in., being 2.0in. below the average of the same month for the last ten years.

The adoption of street tramways is now likely to be sanctioned by Parliament, a committee of the Lower House having on Tuesday, with certain restrictions, agreed to the preamble of the bill now promoted for their establishment.

Science and ART .- A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the the great power of skilled mechanical about is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brocches, Earrings, Lockets, &c., &c., suitable for Wedding. Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to balance-spring of a watch. From its extreme fineand they cannot be too strongly recommended to an incur-cent is about to be piaced in Worcester those contemplating a purchase, especially to Cathedral. The new peal is to cost £3,000, and residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[Advi.]

ELECTRO-ASTRONOMICAL EXPERIMENTS.
THE United States Coast Survey officers have

been engaged for some time past in making astronomical observations, by the aid of telegraph, between the cities of the Far West and Cambridge University. For the purpose of arriving at the difference in mean time between San Francisco and difference in mean time between San Francisco and Boston, the wires of the Western Union Telegraph Company have nightly been connected, for nearly a month past, from one side of the continent to the other, and the ticking of a chronometer in Cambridge other, and the techniq of a combineder in Cambridge University has been observed and recorded in San Francisco with a most remarkable degree of accuracy, This is done by connecting the pendulum of the chronometer at Cambridge with the wire, in such a manner that the main circuit is broken, and instantly closed again at every beat or tick of the timepiece, and the result is that each second of time, as marked and the result is that each second of time, as marked by the chronometer at Cambridge, goes forth from the University on the Atlantic coast, and, with almost the speed of light itself, hurries on over the magic wire, passing through intermediate cities, towns, and villages, severe were over mountains, and doing the open country, that it finally reaches the recording instrument on the passing coast in all of

recording instrument on the resemble coast in all of its original fullness of pulsation.

As any time during an evening of the past month, says file. Buffulo Courier, a visitor to the operating rooms of the Western Union Telegraph Office might have heard one of the little instruments beating the mayo neard one or the little instruments beating the measured time of the sixtieth part of a minute, with the montony and regularity of a chronometer itself. Tick! Tick! One, two, three, four, five minutes clapse, and then the little monitor ceases. minutes elapse, and then the little monitor ceases. Back comes the answer from San Francisco to Boston: "All right; your second signals came good, and have been recorded for five minutes. Go ahead five minutes more!" Again, Tick! Tick Tick! for five minutes, and then San Francisco says again: "All right; are you ready to take my signals?" And the answer from Boston is: "Yest; go ahead." Tick! Tick! Tick! says San Francisco for the allotted five minutes, and Boston says, in his turn, "All right!" But notwithstanding the speed with which the

But notwithstanding the speed with which these pulsations of a clock fly from one side of our continent to the other, it is known that there is a loss, a very slight loss of time in the transmission. How to arrive at this loss, and measure it, is the next question. Nothing easier; a second wire is switched into place, a "repeater" added at Boston, and, presto! 'tis done. Now the clock ticks made at San Francisco rush on the wings of light, overthe 3,000 miles of wire to Boston, and back again to San 5,000 miles of wire to boson, and beet again to see second Francisco over the second wire, and record themselves at the point of starting, in something less than 60 seconds of time, having, in the interval, traversee 6,000 miles. Last Monday night witnessed the successful completion of this last experiment, and

successful completion of this last experiment, and the flight of electricity was actually measured, so to speak, as easily as one measures a yard of muslin. Never befere in the world's history has such a wonderful feat been attempted, and that this has been brought to a successful conclusion is due entirely to the beautiful working of the Western Union Company's wires, together with the assiduous attention and superior ability of its employees. Trace the route on the map, and mark the immense distance so lightly glided over by the subtle fluid. The route is from Boston through Albany, Buffalo, Detroit, Chicago, Omaha, Cheyenne, Salt Lake City, and Virginia City, to San Francisco, and this route is of course doubled, forming, for all practical purposes but a single oircuit.

WORCESTER CATHEDRAL BELLS.

A NEW mode of tolling great bells has just been applied to the 44-ton bell lately cast by Messra. Taylor, of Loughborough, for Worcester Cathedral, and recently hung there. The bell has been hung on a new plan, which with the clock and peal of twelve bells, is designed by E. B. Denison, Q.C., and gives a new effect to bells which are too heavy to be rung in the usual way. According to the "Horological Journal," the gudgeons, or pivots, instead of being round, are wedge-shaped, like those of a scale-beam, and roll on hard brasses very slightly hollowed. The friction is thereby made so little that this great bell can be tolled easily by one man with one hand. It is actually much easier than clappering, or pulling the clapper by a rope, yet brings out the full tone of the bell much more grandly. This tone is half a note below the fourth quarter bell of the Westminster clock. The heaviest bells in England might be made tollable in this way at a very small expense, where most of them are NEW mode of tolling great bells has just been bells in England might be made tollable in this way at a very small expense, where most of them are only inadequately struck by hammer or by clappering, which is the cause of nine out of ten cracked bells. No wheel is required, but only a long lever fixed to the stock. The gudgeons must not be lower than the top of the bell. A series of ten bells and heur-bell is about to be placed in Worcester Cathedral. The new peal is to cost £3,000, and this sum has been subscribed in honour of the Dean (the late Sir Robert Peel's brother) as a testimony

WORKING MEN'S CLUBS AND THE HOLBORN VIADUCT.

HOLBORN VIADUCT.

ON Saturday last, the members of working men's clubs had permission to visit the works now in progress between Holborn and Newgate-street, the permission having been obtained through the influence of the Working Men's Institute and Union. At three o'clock, about eighty members assembled at the Farringdon-street gate, and were conducted to one of the vaults under the central line of the roadwart. The passage and vaults being lighted up, with one of the vaults under the central line of the roadway, the passage and vaults being lighted up with gas for the occasion, and the walls of the vault being well covered with the working drawings of the works, both in general and in detail. Here Mr. Hall described, in a very straightforward and intelligent manner, the difficulties the engineer, Mr. Haywood, met with, whose design the Corporation of London net with, whose design the Corporation of London nultimately selected, through the instrumentality of Mr. Deputy Fry, the chairman of the City Board, in opposition to their own architect, Mr. Burney. The body of members were then taken by Mr. Lidstone through doorways and down steps into passon Mr. Deputy Fry, the chairman of the City Board, in opposition to their own architect, Mr. Burney. The body of members were then taken by Mr. Lidstone through doorways and down steps into passages where persons only could pass and stand in single line. Each of the sewers, subways, and other subterranean passages, were explained by Mr. Hall while the members were in them. Having explored the whole of the underground portion, they ended their earthy travels by passing up through a sewer flap let into the path of the circus at Hattongarden. They then entered the gates at that end, and went over the works above ground, and, truly, from this point of view, the extent of the undertaking is marvellous, there being nothing to obstruct the eye from one end to the other except the framework of timber by which the girders for the bridge are being raised; and even this does not interfere in any way, on account of the curve the viaduct takes, the framework being slightly on one side. The upper portions of the works were closely looked into as the men passed along towards the bridge. At this point they descended the steps of the staircase on the south-west side down to the starting place. They then crossed over Farringdon-street, and passed up the south-east staircase and went over that portion of the works up to St. Sepulchre's Church. Here they had the pleasure of forming the first body of the general public who stood upon and promenaded the finished flagged portion of the path, a circumstance which will be a pleasing remembrance to many of them in days to come. Here some of the members left the body and passed out at the east entrance gate. The others went back to the vault and expressed themselves also satisfied with the arrangements that Mr. Haywood had made for their reception. The inspection occupied about three hours and although the men were much fatigued. and expressed themselves also satisfied with the arrangements that Mr. Haywood had made for their reception. The inspection occupied about three hours, and, although the men were much fatigued from the labour they had undergone in walking down, into, under, and over the vast works, they could not help expressing their admiration of the business-like manner with which the bricks were laid, many of the men being judges of work and material in that line. For our own part, and for the public generally, we feel sure that if similar excursions on large works by working men were allowed to take place, many good results would follow both to the men and to the contractors, as the working class are always open mouthed, and would, working class are always open mouthed, and would, by their expressions, point out practically where faults or errors exist, which could be altered by the contractor before the works have gone too far.

COAL IN GERMANY.

COORDING to the "North Germany Correspondent," Germany is now the second on the list of the coal-producing countries of Europe. In 1850 the English mines yielded 800,000,000 centners (the centner is equal to 110½lb.), those of Belgium 105,000,000, those of France 100,000,000, while not more than 90,000,000 were gained from the German coal fields. The total consumption of Europe in that year has been estimated at about 1,300,000,060. In 1867, on the other hand, not less than 3,000,000,000 In 1867, on the other hand, not less than 3,000,000,000 centners were consumed, and the proportion contributed by the various nations had changed, contributed by the various nations had changed, England, it is true, still stood first on the list with 2,000,000,000 centners, but next came Germany with 480,000,000. Of these, 48,000,000 came from Saxony, and 420,000,000 from Prussia. Germany imports about 12,000,000 and exports more than 70,000,000 centners of coal. Russia, France, Switzerland, Holland, and Belgium are her chief foreign markets, but the German cannot compete with English coal in the districts that border on the North Sea and the Baltic. Hamburg, for instance, does not consume more than 50 centners of German coal. This is generally attributed to the difficulties does not consume more than 50 centners of German coal. This is generally attributed to the difficulties of transport, but we should be inclined to attribute it at least in part to the inferiority of the article. The chief coal-fields of Germany lie in Upper Silesia (yield above 100,000,000 centners), Saxony (48,000,000 centners) on the Saar and on the Ruhr (120,000,000). None of these, with the exception of the Saar district are worked as completely as their extent would admit.

### Correspondence.

BOURNE'S WHIRL-WHEEL STAR POINTER. TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

TO THE EDITOR OF THE "MECHANICS" MAGAZINE."

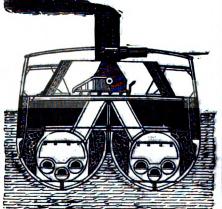

SIR,—Several years ago, I devoted considerable study to the application of the gyroscope for the objects contemplated by Mr. Bourne. I came to the conclusion that those objects could certainly be attained, but only with apparatus of excessively accurate, refined, and expensive construction. I am sorry to say that I do not think that Mr. Bourne's plan would answer. He appears to rely on what he terms "the stability of the planes of rotation," but to give accurate results such stability must be absolute; whereas it is impossible to render it absolute, not merely because of physical difficulties and imperfections, but also because the laws of mechanics do not admit of it, except in the suppositive but practically impossible case of an infinite velocity of the wheels. As regards details, I would observe that Mr. Bourne has more wheels than are necessary, involving extra complication and expense. observe that Mr. Bourne has more wheels than are necessary, involving extra complication and expense. Three wheels are quite sufficient. I also think it is a mistake to propose to make them large. The power required to drive them, if 3ft. in diameter, would be found to be a serious consideration.—I am, Sir, yours, &c., Sir, yours, &c., Glasgow, April 10.

### SHIPS OF WAR.

SHIPS OF WAR.

SIR,—We look into all the modern appliances for working heavy guns on board ship, and find, with many a mass of complicated machinery, it ill-suited for the rough usages of war. We have for long sought a class of vessel for coast and harbour defence—a powerful ship, adapted for the percussive mode of warfare; a speedy and stable vessel, suited for ocean navigation. That such a vessel must be a steamship, no one will dispute. She must be fitted with powerful machinery, for attaining great speed and for steaming off a lee shore. Sails may be entirely dispensed with in such craft, as their powers of endurance at sea will just be regulated according to the amount of fuel they can carry. If the hydrocarbon method can be introduced, a great step will be gained. gained.

Step by step we have worked out the old salts; their occupation is gone, and modern Jack must be taught quite differently—but how are we to commence? Are the guns to be trained in a revolving turret, on a broadside, in fixed central turrets, in that unhappy larboard and starboard end-on fire? With Captain Scott's system, Armstrong, the Moncrieff gun carriage, or how? That I must leave for others to decide; so I will now introduce my "twins," suited for them all. An explanation is given further on, and I will merely state that for the twin screw mode of propulsion I have sought a better form than originally practically demonstrated by the late Mr. G. Rennie, C.E. I had an early opportunity of forming an opinion as regards twin screws, and there can be no doubt in my mindthatthe deeper the vessel is the better—that is, if she is not a great square tub, with the screws bracketed close to the vessel. I believe each screw should propel its own Step by step we have worked out the old salts: square tub, with the screws brakered close to the vessel. I believe each screw should propel its own section; a twin ship, propelled in a twin manner; a river of water, flowing through and under the body of the "Hercules," or with a much smaller vessel, as

shown in the sketch herewith, so that the screws act in a more solid fluid.

There are certain difficulties to contend against firstly, there are two inimical sections, having only one bow, common to both, this form giving great strength to resist percussion, as there are four thicknesses of plating at the bow, with a central division let into the bar keel on the centre line. This strength to resist percussion, as there are four thicknesses of plating at the bow, with a central division let into the bar keel on the centre line. This plated all over, the armour of the monitor type, with conical fixed turrets, to suit the Moncrieff system. There will be a light spar deck, and the outward form, above water, will just be like any ordinary ship, the length being not less than six times the beam, the draught of water for being commissioned by the 30th inst.

being about 20ft. I need scarcely say that the engines will be of the most improved description, while the boilers will be constructed for the indicated power. The launching my bark on the billows of criticism, I am confident that she will ride gallantly through the seething breakers of prejudice, and in some future time, when steaming swiftly against the imaginary foe some always seem to have in view, that our endeavours and time have not been altogether thrown away.—I am. Sir. yours. &c.. thrown away.—I am, Sir, yours, &c.,
John G. Winton.

## Haval, Military, and Gunnery Items.

THE flying squadron is to consist of the "Liver-pool" (flag), "Liffey," "Phoebe," "Endymion," "Bristol," "Clio," and "Scylla." Some of these ships are already in commission, some are not yet quite ready, and whilst others are, as yet, on foreign

M. DUPLY DE LONE, the well-known French naval engineer, has been permitted by the Emperor to resign his post at the Ministry of Marine, and has announced his intention to come forward as a candidate for the representation of one of the seaport towns in the next Legislature.

Ir will be remembered that the iron frigate "In-It will be remembered that the iron frigate "Inconstant" lost her rudder on a trial trip down to the Haven from Pembroke. A new rudder, constructed on the balance principle, has been successfully east at the dockyard foundry. It is formed wholly of gunmetal. The "Inconstant" is expected to be undocked on the 26th, and will leave for Portsmouth on the 28th, where she will be put in

A RETURN just published shows that of the correspondence despatched to the United States during the past year, Messrs. Cunard received sea postage amounting to £28,686, Messrs. Inman to £23,390, the North German Lloyd Company to £11,772, and the North German Lloyd Company to £11,772, and the Hamburg American Company to £5,157. These sums are computed at 1s. per oz. for letters, 3d. per lb. for papers, and 5d. per lb. for books. It should be remarked that the contract with the Hamburg American Company terminated on the 31st of October in last year.

WE notice that the Government of Victoria is WE notice that the Government of victoria is advertising for tenders for a monthly service for mails and emigrants between Great Britain and Melbourne via the Cape. The vessels—steamships, of course—are not to be under 2,500 tons register, and course—are not to be under 2,500 tons register, and are to possess accommodation for 500 steerage passengers. The dates of despatch will be fixed by the Postmaster-General of Victoria. Tenders are receivable by Mr. George Verdon, of 8, Victoria Chambers, Westminster, the agent-general for Victoria, up to October 8. The postmaster-general at Melbourne will receive tenders until the arrival of the residue at Melbourne. the mail due at Melbourne, November 25.

THE Board of Trade have awarded a telescope to Captain Von Schantz, of the Russian barque "Gefion," for his humanity in receiving a portion of the ship-wrecked crew of the barque "Aldivalloch," of Sunwrecked crew of the barque "Aldvalloch," of Sunderland, on board his vessel, on the 21st of January, 1869. The "Aldivalloch," was from Bourgos to Falmouth, with a cargo of barley. On the 15th she sprang a leak, and on the 19th the crew abandoned sprang a leak, and on the 19th the crew abandoned her in a sinking condition, in lat. 37-92 N. and long. 8-56 W. The master and crew were received on board the "Meggie Armstrong." and five of them were subsequently transferred to the barque "Gefion," which remained eighteen hours by the "Meggie Armstrong" to effect their transfer.

### Miscellanea.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending April 10, was 4,217. Total number since the opening of the Museum, free daily (May 12, 1858), 1,546,537.

THE death of Mr. Mm. Bradbury, of the well-known publishing firm of Messrs. Bradbury and Evans, is announced. He died at the age of 70; and had been many years in business with Mr. Frederick Mullet Evans as a publisher.

IT appears that, according to the octroi returns, Paris consumed, in 1867, 50,000 deer, 625,000 partridges, 80,000 pheasants, 200,000 snipes, 40,000 quails, 45,000 plovers, 400,000, turkeys, 700,000 eapons, 700,000 ducks, 1,700,000 geese, 4,500,000 chickens, 1,700,000 larks, 1,700,000 rabbits. The value of all is stated at £1,040,000.

WE are requested to state that the Diplomes WE are requested to state that the Diplomes d'Honneur, gold and other medals, and certificates of Honourable Mention, awarded to British exhibitors by the International Jury at the Havre Maritime Exhibition, can now be obtained on application to Messrs. J. M. Johnson and Sons, of Castle-street, Holborn, the Commissioners for the United Kingdom.

of those frightful accidents which un-ONE of those frightful accidents which un-fortunately so often accompany the carrying out of great public works occurred last Tuesday at Saltburn-by-the-Sea. An iron bridge 100ft. in length across the famous glen along which Skeltonbeck runs to the coast, was nearly completed, when an immense iron girder slipped from its holding and knocked down one of the piers, killing three men.

DURING the first fortnight of March, the length driven at the Mont Cenis tunnel was 67:20 m., of which 40:10 were on the Italian side, at Bardonneche, and 27:10 on the French side at Modane. The position of these works up to March 15 was the following:—Length driven at Bardonneche, 6,514.70; Length driven at Modane, 3,939; Total length driven, 9,453.70; Remaining to be driven, 2,766.39; Total length of tunnel, 12,220.

THE number of visitors to the South Kensington THE number of visitors to the South Kensington Museum during the week ending April 10, 1869.

was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 13,983; Meyrick and other galleries, 3,043; on Wednesday, Thursday, and Friday (admission 6d.) from 10 a.m. till 6 p.m., 2,434; Meyrick and other galleries, 285; total, 19,745. Average of corresponding week in former years, 12,174. Total from opening of Museum, 9,338,369.

LAST week some workmen were employed in digging the foundation of a house on the Cowley road, Oxford, when they came upon a large quantity of old coins, enclosed in an earthenware pot. The pot was broken by the workmen, and the coins were dispersed and taken away by a number of persons who happened to be near the spot. They were all of silver, and of different sizes, the largest being somewhat smaller than the present shilling. The coins are said to be of the reign of Edward I.

AT a recent meeting, the Council of the Emperor of Russia sanctioned a decree enacting that the former practice of coining Russian gold ducats of the value of three roubles shall be resumed. Like the half-imperials, each piece is to have the arms of the Empire on one side, and on the other the date, the mint stamp, and the legend "teheestavo zolota" eighty-one "dolyah," i.e., eighty-one parts of a "zolotnik" of fine gold. The zolotnik is the ninety-sixth part of the Russian pound.

LETTERS have been received at Gotha from the German discoverer, Carl Mauch, who is making an arrelation expedition in Southern Africa. The German discoverer, Carl Matich, who is making an exploring expedition in Southern Africa. The letters are dated November 29, 1868, and announce that he has accomplished a very important journey, although he had encountered great dangers. He started northwards on May 8 from the Potschefs river, and arrived at Inyati on October 18, having explored countries, which had never been travered. explored countries which had never been traversed by Europeans. From this point he intends this April to endeavour to penetrate northwards as far the Equator.

THERE is every probability of the meeting of the Royal Agricultural Society being held in Oxford in vear 1870 The formal invitation from Oxford was received and considered by the council at their last meeting, and met with such a favourable reception that it is all but certain the invitation will be accepted. A committee of five has been appointed the council to inspect the site for the show ground and the other accommodation which they require. Several hundred pounds are still required to complete the fund of £4,000 which it is necessary to

REFERRING to rumours recently current in Shetland, the Lerwick correspondent of the "Scotsman writes:—"It seems that gold has been discovered in Uist. It is said to exist in two localities, but whether it will pay for the working has not been determined yet. Mr. Walker, factor for the Garth and Annslerae estate, has made some offers to 'proand Annsiera estate, has made some ones to properly spectors; but they have not been accepted, and the majority seem inclined to depend rather on the 'golden ears' of the autumn field than to the gold of the 'new diggings,' and, therefore, are wisely devoting their attention to their crofts, previous to the commencement of the summer's fishing.

THERE has lately been issued a return of the names THERE has lately been issued a return of the names of the Council of India, with dates of appointments according to seniority; stating also their ages last birthday; whether previously a director of the East India Company, and, if so, from and to what dates; whether having served or resided at any time in India, and, if in the service, in what branch, and from and to what dates; the annual amount of any are resided as the service of the pay, pension, civil fund, or other allowance now re ceived for such Indian service; and the salary an allowances, if any, received as member of the Council; and a similar return of the six secretaries of departments, and of the accountant-general, the auditor, and the director-general of stores.

PARIS is the best market in Europe for leeches. PARIS is the best market in Europe for leeches. The mouth of the Danube is now the best fishing ground, and no less than £120,000 in value of leeches are annually sent to Paris from Trieste. The best leech is said to be a native of Australia, as he does his work in a shorter time than any other. The Viceroy of Egypt has granted a monopoly of 3,000,000 leeches annually, which are to be found in the bed of the Nile after the periodical inundation of that river, to a French dealer. On arriving in Paris that river, to a French dealer. On arriving in Paris those not required for active duty are sent to Gentilly, where they are lodged in reservoirs pro-vided with greasy mud and filled with greenish water.

water.

An official report has been prepared showing the amount and value of the gold obtained and exported during the first nine mouths of 1868. The yield of gold was 1,274,661oz. 9dwt., of which 1,248,704oz. 18dwt. were exported. The figures show a decrease on the returns of 1867 on every quarter. The number of miners employed was 63,482. Machinery having an aggregate of 20,683-horse power was worked on the various fields, and the gross value of mining plant was £2,133,855. There were 8374 miles of auriferous ground already worked upon, and 2,561 distinct quartz reefs were proved to be miles of auriterous ground aiready worked upon, and 2,561 distinct quartz reefs were proved to be gold bearing. The lowest price given for gold was £3 per ounce for some from Gipps Land, and the highest was £4 2s. 3d. for gold taken from the central division of the great Ballarat fields.

central division of the great Ballarat fields.

THE "San Francisco Herald" says that those engaged in the culture of silk in California have grown no less than 1,175,000 mulberry trees. They are apportioned as follows:—Los Angeles, 50,000; Santa Barbara, 100,000; Santa Clara, 150,000; Nevada, 50,000; Sacramenta, 425,000; Yolo, 400,000. The total production of cocoons in 1868 amounted to 1,350,000, equivalent to 1,917lb., allowing 704 cocoons to the pound, representing a cash value of 3,676 dols. 75 cents. To be added to this was the egg crop of 7,350oz., commanding in the market 8 dols. per ounce, amounting to 58,800 dols. There will be a vast increase in the production of cocoons this year, as three cocooneries will hatch 600oz. of eggs, sufficient to produce 18,000,000 cocoons.

## Patents for Inbentious.

### ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

II J. JONES and G. E. WILKINSON, Wattling-street

Mannfacture of paste board, Dated September 26

The patentees coat a sheet of paper on both sides with The patentees coat a sheet of paper on both sides with paste or cement, by passing the sheet through a pair of rollers, each partially immersed in a trough containing paste or cement. After the paper has been so coated on both sides, two other sheets of paper are brought into contact with it, one against each of its sides, and the three sheets are pressed together by being passed through a second pair of rollers, and may then at once be cut into sheets, or may be wound on to large drums, to be subsequently cut up in another machine. The combined sheets of paper so cut into lengths are afterwards pressed in the ordinary manner.—Patent completed.

2962 G. F. MORANT, Frenchay. Artificial fuel. Dated September 26, 1868.

September 26, 1868.

The patentee produces an artificial fuel by saturating peat or turf with dead oil—or creosote, by preference—after thoroughly drying the peat. The air is exhausted therefrom, and the dead oil or creosote then admitted to the vessel containing it. Different proportions of peat and dead oil or creosote may be used, but it is preferred to make the peat absorb about one-tenth of its own weight of the dead oil or creosote.—Patent completed.

weight of the dead oil or creosote.—Patent completed.

2963 W. GALLET. Sheffield. Manufacture of cast steel.

Dated September 26, 1863.

The object is the conversion of iron ores into cast steel. For this operation, brown or red hematite ores are preferably taken, and after having broken and washed them, if necessary, they are mixed with a cement composed as hereinafter stated, and afterwards melted in furnaces or pots. The result is cast steel. The cement which is employed is composed as follows:—Carbonate of lime, 37 parts; clay, 13 parts; oxide of manganese, 3 parts; resin, 3 parts; wood charcoal, 50 parts. The above substances are mixed with about 10 per cent. of water, in which from 3 to 20 per cent. of carbonate of pofash and 1 per cent. of salt have been previously dissolved.—Patent completed.

2964 H. GIBSON, Musselburgh. Manufacture of tebacco.

completed.

2964 H. GIBSON, Musselburgh. Manufacture of tobacco.

Dated September 26, 1868.

The tobacco leaves, in a prepared state, are placed on a travelling band or belt, which carries them forward to the spinner, who arranges the leaves in a proper manner, and after the leaves have been twisted or spun by the action of a revolving frame and bobbin placed at the other end of the machine, the twist is carried between levelling rollers, which roll down the inequalities in the work. After passing through the levelling rollers, the twist is oiled previous to being coiled upon the bobbin. In order to produce a uniform coil, motion is given to the bobbin endwise alternately backwards and forwards by means of a cam upon a lever. The machine is actuated from a shaft, which is situated underneath it, and may be revolved by means of treadles coupled to cranks, actuated by the spinner or by other motive power. The bobbin is fitted with a friction strap to regulatelihe rate of coiling the twisted tobacco.—Patent completed.

of coiling the twisted tobacco.—Patent completed.

2965 F. B. Dereing, Victoria Chambers, S.W. Borisg rock, &c. Dated September 26, 1868.

This consists, first, in regulating (by means of a piston valve, or other form of valve or cock), the supply of water or other fluid (preferably an incompressible fluid) to, and the outlet of such fluid from, a cylinder, or a pair of cylinders, attached and adjacent to the main cylinder. The valve is worked by a piston in a cylinder in the manner described in the specification of letters patent, dated June 10, 1867, No. 1704, by motive fluid distributed from the main cylinder to the small cylinder, the piston of which is connected to the valve. Instead of attaching the adjacent cylinders to the boring cylinder, the piston or pistons of such adjacent cylinder or cylinders may be attached to the working or boring cylinder, the sdjacent cylinder in this case being fixed. The adjacent cylinders have each a fixed piston, and a supply of compressed air or other motive fluid may be maintained at its front, so much of each of the cylinders as is behind the piston o

pistons being filled with water or other fluid. A tube leads pistons being filled with water or other fluid. A tube leads from the piston valve to a reservoir containing the water. Second, in an improved mode of securing the tool in the end of the piston rod. For this purpose, the end of the piston rod or socket is threaded to receive a nut, and the position for the ordinary key is made adjustable, the nut is screwed up, and the key which jams against it is driven in; wear is thus compensated for, and washers dispensed with. In some cases, grooves are formed in the nut to in; In some cases, grooves are formed in the nut to the edge of the key; the nut is thus prevented turning .- Patent completed.

2967 J. Shepperd, Whitfield. Furnaces. Dated September 28, 1868.

This consists in the use of an escapement wheel with This consists in the use of an escapement wheel with pallets and pendulum, as in the common clock; the escapement wheel works loose on the end of a drum or barrel carrying a ratchet wheel, the ratchet being attached to the said escapement wheel. A cord is wound on the said drum or barrel, one part of which passes to the damper and moves the same by the use of a lever and pulley; the other part of the cord passes over a pulley or pulleys to the stoke hole, and has a weight attached thereto to act through the mechanism on the damper and gradually close the same, but not entirely shut off the draft.—Patent abandoned.

abandoned.

2968 C. D. ABEL, Southampton-buildings. Converting cast into wrought iron. (A communication). Dated September 28, 1868.

The fluid cast iron, whether direct from the blast furnace, or remelted, is taken and poured into a suitable receptacle in a stream, the flow of which is so regulated that the oxides (say, iron ore or cinder, or any other convenient and suitable oxidizing substance), can be stirred or mixed into it. The fluid metal will rapidly become pasty, and then solid, so that it is important to perform the operation quickly, and if the hardening is inconveniently rapid the oxide should be used hot.—Patent abandoned.

rapid the oxide should be used hot.—Patent abandoned.

2869 W. M'ADAM, Glasgow. Omnibus traffic. Dated
September 28, 1868.

This relates to tramways, wheels, and carriages. The
tramway is composed of wrought iron, malleable cast
iron, or steel plates or rails, laid in shallow grooves formed
for them in the roadway, whether such roadway is paved
with stone or wood, or is macadamized. The improved
wheel is formed with what may be termed a stepped tyre,
that is, having one part of one diameter and the other
part of a greater diameter. The part of smaller diameter
is for running on the raised surface of the improved rail,
and the larger part acts as a flange to keep the wheel on
the rail. The improvement in carriages consists in making the body of the carriage separate from the frame or
bogic which rests immediately on the wheels, and in
arranging the parts so that the body may be turned as on
a turntable.—Patent completed.

2370 J. Gregory, Bristol. Preparation of animal char-

2970 J. GREGORY, Bristol. Preparation of animal charcoal. Dated September 28, 1868.

This relates to an improved construction of retort. The retort is constructed by inserting in a revolving heating cylinder a plate, or series of plates, having perforations therein of a rectangular or other suitable shape, made in direction tables to the form the series of the suitable shape. a direction inclined from the axis of the cylinder. completed.

a direction inclined from the axis of the cylinder.—Patent completed.

2971 G. A. C. Bremme, Liverpool. Univisiting strands. Dated September 28, 1868.

This relates, first, to untwisting strands and other twisted or spun materials. Second, to feeding untwisted or non-twisted strands to backle or dressing cylinders; and, third, to dressing, combing, or picking the materials or three. The machinery for untwisting consists of a rotary feeder, composed of parts about to be explained. Two untwisting rollers are mounted in a frame which rotates on its axis at right angles, or nearly so, to the axis of the rollers; the journals of the frame, one at each side of the rollers, are hollow. On the axis of one roller right and left handed worm wheels are keyed; these wheels reach into pockets, one of which holds the corresponding worms or screws, on which is fastened a toothed wheel gearing into another wheel fixed on the pedestal of the hollow journals. The machinery for dressing, combing, or picking the fibres consists of two or more backle combe carried by side plates on a rotating shaft, and each provided with a hinged cover having holes or slots for the teeth to pass through. The dressing of combing machine will in most cases be combined with the rotary feeder before described, the fibre passing directly from the discharging journal of the latter to the backle teeth, and the hollow journals being driven by gearing and straps from the cylinder or comb shaft, or from counter shafts, if several machines are arranged in a row.—Patent completed. pleted.

2972 R. DUNCAN, Billericay. Earth closets. Dated September 28, 1868.

tember 28, 1868.

The patentee provides the earth reservoir or hopper with trunnions at its upper part, by which he suspends the hopper in bearings at the back part of the casing above the level of the seat. This reservoir or hopper he further provides with a double bottom, the one being placed a few inches above the other, and the false bottom having a central aperture through which the earth falls on to the lower bottom of the hopper, forming a heap, the flow of earth ceasing automatically when it rises to a level with the aperture in the false bottom. An opening is also made in the front of the hopper at the lower part below the false bottom, and just below the level of the seat, which opening he prefers to provide with a shoot for guiding the earth downwards on to the soil.—Patent completed. pleted.

2973 J. ROBINSON, Heston. Ploughs. Dated Septem

ber 28, 1868.

The cultivating tine or grubber is carried between the handles or yokes, and immediately behind the body of the plough. The tine or grubber is arranged so that it can rock in between the yokes, and from it, near its lower end, a draft chain or rod is passed to the beam of the plough, to a point in front of the body or frame.—Patent completed.

2974 T. Briggs, Manchester. Metal bands. Dated September 29, 1868.

This consists in connecting the ends of metal bands by punching at each end thereof two or more longitudinal slits with corresponding projections and recesses; these projections and recesses fit each other, leaving a transverse slot open between them, through which a key or cotter is driven, thereby connecting the ends of the bands. Also in punching one or more slots in the ends of the band; these

slots are larger at one end than the other; studs with flat heads are introduced in each slot to connect the ends of the band. Also in certain improved appuratus for punch-ing and bending the ends of the metal.—Patent completed.

THE

2975 J. SMITH, Manchester. Weaving and cutting fustions.

2975 J. SMITH, Manchester. Weaving and cutting fustians. Dated September 29, 1868.

This relates to patent, No. 837, dated April 4, 1864, and consists in working the rod by a hydraulic or other pump acting on a piston fixed to the end of the said rod, or on the end of the rod itself; this pump is worked by a cam or tappet. The second part of the invention consists in the application of fluied or toothed rollers to the taking-up motion of looms.—Patent completed.

2976 J. Wadsworth, Manchester. Utilizing heat of store, &c. Dated September 29, 1868.

The patentee makes a casing or framework of sheetiron rother metal, in the inside of which he fixes a door or shutter near the centre, working or swivelling on pivots, supported at each end by the framework or casing to the upper edge, and at one end of the shutter or door he attaches a connecting rod, by means of which such door or shutter can be opened or partially closed at pleasure. This apparatus he fixes in the flue of the chimney above the fireplace, so that when fixed, the door or shutter can be opened or partially closed by the connecting rod, which hangs down by the side of the fireplace, and when the fire is kindled, the door or shutter can be opened or or shutter can be partially closed, and thus reduce the area of the flue, and prevent an excessive current of air from rushing up the chimney and carrying with it the heat from the lire.—Patent completed.

heat from the fire.—Patent completed.

2977 W. E. Geder, Wellington-street. \*\*Reimming apparatus.\* (A communication). Dated September 29, 1868.

This apparatus is a belt, which is placed under the arms, and buckles over the stomach and belly. It is composed of two tin boxes, hermetically closed; the two boxes are tied together by means of a tinued iron plate, placed at the back of the apparatus, and secured by three rings. A small rod or iron wire pin is inserted in these three rings, to unite the two boxes indissolubly together. A double belt, such as those used for gymnastic exercises, forms the front of the apparatus, and permits its being fitted as close as may be desired to the body of the person using it. This belt, by reason of the shape of the apparatus, does not pass all round the interior, but is fixed on each of the two boxes to a vertical strip of tinned iron.—Patent completed.

2978 A. M. Clark, Chancery-lane. \*\*Raising and lovering\*\*

2978 A. M. CLARK Chancery-lane. Raising and lowering cithis. (A communication). Dated September 29, 1868.

2978 A. M. CLARK. Chancery-lane. Rating and lowering weights. (A communication). Dated September 29, 1868. This consists of a wood or metal framing, carrying the various parts of the apparatus, a crank handle or handles for imparting motion to the apparatus by hand, for which wheel driving gear may be substituted, and of friction rollers mounted loosely on the tripled cranked shaft, each of the cranks supporting a lever. These levers are provided with plates carrying weights, the position of which is adjusted according to the weight to be raised or power to be produced. Each lever is also provided with a pawl or catch, which are caused to act on ratchets keyed on the shaft.—Patent completed. Patent completed.

duced. Each lever is also provided with a pawl or catch, which are caused to act on ratchets keyed on the shaft.—Patent compieted.

2979 J. T. Irwin, Chicago, U.S.A. Illuminating apparatus. Dated September 29, 1868.

This relates to the combination with the burner of a lamp or lantern of a tube or tubes, so constructed and arranged that a current of air generated by the flame is caused to imping upon the flame, and promote a more perfect combustion, particularly from oils which are rich in carbon; second, to the combination with the burner, and with the conducting device above mentioned, of a globe; third, in the combination with the burner, and with the conducting device above mentioned, of a chamber placed near the base of the burner; fourth, in the arrangement of the conducting tubes above mentioned in such a manner as to form guards for the protection of the globe; fith, in the construction and combination with the conducting tubes above mentioned, a globe or its equivalent and a horizontal plate or a plate, inclining upward towards the centre, and perforated with small holes; seventh, in the combination with the burner, the conducting tubes and the globe or its equivalent to be raised up from the seat without disconnecting it from the conducting tubes; eighth, in the formation of the sides of the cap or the lantern with an inwardly and upwardly projecting flange at the top; ninth, in the combination with the sides of the cap of the lantern of a top plate or dome larger in diameter than the sides of the cap; tenth, in forming the sides of the cap of the lantern with projections made in one piece with it, and securing those projections in holes in the dome.—Patent completed.

2980 E. T. Hughes, Chancery-lane. Gas burners. (A communication). Dated September 29, 1868.

This consists in the arrangement of a rod of suitable material placed in such relative position to the flame, and indirect or indirect connection with the valve, so that the heat of the flame expands the rod to hold open the supply of gas, and s

2981 A. H. BRANDON, Paris. Watch-case spring. Dated

2981 A. H. BRANDON, Paris. Watch-case spring. Dated September 29, 1868.

This consists in replacing the two springs usually employed for the catch and springing of the cover by one spring, which said spring its into the case by its own elasticity, and does not require, as in the use of two springs, to be fitted into the case and fastened by screws screwed into the case.—Patent completed.

2982 I. Tearry Patelliar Damping and making pages.

screwed into the case.—Patent completed.

2982 J. Foster, Halifax. Damping and making paper for cartridges. Dated September 29, 1868.

This relates to a patent, dated August 28, 1866, No. 2218.

The patentee constructs a machine consisting of suitable framework, on which, at one end, is mounted a winsel or pair of conical studs to receive and support a roll of the paper; also at the other end is another winsel to which rotary motion is given, so that the paper may be unrolled from the first winsel upon the second. Between each of these winsels is mounted a cylindrical brush, or a roller covered with felt, or other absorbent material, and under it is a vessel to contain water, both of which are attached to a lever and stop rod, and hinged so that the roller may readily be placed in or out of contact with the paper whon starting and stopping the machine.—Patent completed.

2083 A. V. Newton, Chancery-lane. Boots and shoes.

2983 A. V. Newton, Chancery-lane. Roots and thoes. (A communication). Dated September 29, 1868.
Horn is employed in place of leather in the manufacture of boot and shoe seles. The soles, with or without raised

heels, are moulded into the desired shape by the aid of metal dies and mechanical pressure, after the manner usually employed in moulding buttons and other articles in horn.—Patent completed.

in horn.—Patent completed.

2934 W. HALLAM and H. J. MADGE, Swanses. Utilizing
tin shearings. Dated September 29, 1868.

The shearings are packed in frames or boxes of any
convenient or suitable size and form, and then apply
pressure to the shearings by a plunger or otherwise, to
render the bundles compact. The patentees next secure the
now compressed bundles with bands of wire or selected
strips of the shearings, having laid these bands within and
transversely of the frames or boxes before packing in the
shearings. The bundles thus made and secured are placed
alone and naked in a balling or other suitable furnace,

strips of the shearings, having laid these bands within and transversely of the frames or boxes before packing in the shearings. The bundles thus made and secured are placed alone and naked in a balling or other suitable furnace, bringing them to a welding heat. The heated masses are now quickly submitted to a squeezer or hammer, and thereby form them into a bloom, which bloom is at once passed through the rolls of an adjacent rolling mill and converted into a bar.—Patent completed.

2985 L. HANNART and N. A. AUBERT, Clerkenwell Moviding dixes for letters, &c. Dated September 29, 1869.

The bottom of the tool consists of a circular flat plate of metal upon which rests loosely another circular plate of metal of smaller diameter than the former plate; this smaller plate is formed with a fillet about its upper edge to serve as a shoulder for the engraved dies to be forced against, and thereby to bring the segmental dies close together, so as to form them into an entire circular die or mould; these segmental dies are each connected by a serow to the bottom plate of the mould, the heads of the said screws, each taking into an oblique slot or groove formed in the said plate; grooves or slots are also formed in the filleted plate above mentioned, radiating from the centre thereof, and into each of these radial slots a pin takes.—Patent abandoned.

2986 H. J. and J. W. GIRDLESTOR, Westminster. Pre-

takes.—Patent abandoned.

2986 H. J. and J. W. GIRDLESTONE, Westminster. Preventing compass deviations. Dated September 29, 1868.

This relates to the depolarization or neutralization of the magnetism of iron ships. For this purpose the patentees employ either an elastic spiral or spirals with battery and apparatus, such as that described in the specification of a patent dated September 13, 1867, No. 2592; or electro-magnets with a battery or ordinary horse shoe or permanent magnets.—Patent abandoned.

2987 E. HORTON, Birmingham. Chandelters and gas filtings. Dated September 29, 1868.

This consists in making the pulley wheels, rosettes, and balance weights, and the other parts used in the construction of chandeliers and gas fittings, of glazed vitreous earthenware, instead of making the same parts of metal, as is now customary.—Patent completed.

2988 G. DAWS, Penge. Opening and closing gates. Dated

2988 G. DAWS, Penge. Opening and closing gates. Dated September 30, 1868.
This relates to patent, No. 369, dated February 9, 1867. One of the posts of the gates to which the power is applied carries a pulley, as described in the specification of the patent before referred to. A chain or wire rope passes round the pulley, one end of which is led over another pulley with a weight attached; the other end of the chain goes to one arm of a bell crank lever, the other arm of which has a chain or wire rope attached, leading to a crank on the other side of the line of rails. A stud, by preference T-headed, is fitted to each of these bell cranks, and takes into a slot or slotted link, united to rods extending along the line of rails. One of the rods or series of rods extends along the line for, say, a quarter of a mile, where it is united or joined to a notched plate, resting on a suitable bed, and on which, at certain times, it is free to slide. A chain is connected to the other end of this plate, passing over a quadrant lever.—Patent completed. pleted.

pleted.

2989 W. GADD and J. MOORE, Manchester. Looms.
Dated September 30, 1868.

This consists in an improved method of regulating the amount of tension in the warp after it has left the warp beam. The warp beam, as most usually constructed, is fitted at each end with a pulley or an equivalent thereto, around which is coiled two or more "turns" of a rope band, or chain, one end of the band being connected to a spring, and the other end to a weighted lever, or to a second spring. The strain on the said band requires to be decreased at intervals during the weaving, as is well understood. The invention relates more particularly to those arrangements in which spiral springs are employed to strain the bands.—Patent completed.

2990 H. JRWITT. Kentish Town. New came. "silver chimes."

those arrangements in which spiral springs are employed to strain the bands.—Patent completed.

2990 H. Jewitt, Kentish Town. New game, "silver chimes."
(A communication). Dated September 30, 1868.

This relates to means and sparatus for playing a new game, called "silver chimes," and consists in placing rings, hoops, or gateways having swinging targets and bells attached thereto, around a central flagstaff on a lawn or (for an indoor game) on a table or board provided for the purpose. Any convenient number of players in turn strike or propel balls, which may be painted or stained with various colours, from concave wedges driven into the lawn, or from the surface of the said board or lawn by mallets or maces, which may be also painted or stained. The said balls are struck, when required, in the direction of, and so that they may pass through the rings, which have targets upon them, furnished with a bell or bells, caused to ring by the ball striking such targets or disca. Suitable mottoes, sentences, or devices are also statched thereto or inscribed thereon. The flag or banner (also having a suitable motto or device thereon) is placed at any convenient part of the board, table, lawn, or other place where the game is employed.—Patent completed.

2991 V. Jugi. Nice, France, Propelling, steering, and

place where the game is employed.—Fatent completed.

2991 V. Jugl. Nice, France. Propelling, steering, and
turning ships. Dated September 30, 1868.
This consists in forcing a jet or jets of water in a contrary direction to the desired course of the ship or vessel.
A cylindrical or other shaped chamber, in which works
an air and water-tight pistou, is placed at a suitable distance below the water-line of the ship or vessel, and a
reciprocating motion is imparted to the piston by a steam
engine or other motive power.—Patent completed.

2992 J. MABSON, Norwood. Candlesticks. Dated Sep-

2992 J. Masson, Norwood. Candleticks. Dated September 30, 1868.

An upright spindle or rod, formed at its lower end into a male screw, carries on the top a cup, or socket, or plate, with a vertical pin or point to receive the candle. Clips are fastened at the upper part of the spindle. On the spindle, below the clips, is a nut or threaded collar, which, when screwed up, causes the clips to close and embrace the lower part of the candle.—Patent completed.

2996 J. LAMBERT, Norwich. Raising easter. Dated Septicher 30, 1868.

As the top of the suction pipe is fixed a valve opening into a space or chamber between this valve and another above it, fixed in the top of a hollow air-tight plunger, forming a cylindrical sir-tight chamber, closed at top and bottom, and encircling the suction pipe, but of such diameter as to leave a space for water between the outer surface of the esid chamber and the interior of the outer cylinder or pump barrel.—Patent completed.

2994 A. LAFAYNE, Newcestle-upon-Tyne. *Sice* ated September 30, 1868.

2994 A. LAPANE, Newcastle-upon-Tyne. Steam gauges. Dated September 30, 1868.
The fiuld, the pressure of which is to be indicated, acts in a cylinder upon a piston or plungar, the rod of which, by rack and pinion or otherwise, operates a pointer, and at the same time by arms and pulleys or studs; the piston rod acts on weighted levers, causing them to move from a position vertical or nearly so to a horisontal one, dependent on the pressure applied in relation to the weights of the lever.—Patent completed.

2995 W. RIGHARDON, Oldham. Classing seed, &c.
Dated September 30, 1868.
This consists of a series of prongs or spikes, to which a
reciprocating or travelling motion is imparted, while, at
the same time, they are caused, during their forward
movement, to rise through a grid, on which the material
rests, and then to be withdrawn therefrom.—Patent completed.

movement, to ruse throngs a grie, on which such associated rests, and then to be withdrawn therefrom.—Patent completed.

2996 W. E. Newton, Chancery-lane. Treating metals. Dated September 20, 1868.

This relates to treating metals so as to remove from them phosphorus, sulphur and silics. A suitable furnace is first constructed, with a proper vessel set therein, in which to treat and fuse the material used for this purpose, which is the cyanide of potassium or other fusible compound, containing cyanogen, combined with one or more metals together, with one or more of the compounds of sodium or potassium, such as the chloride of sodium, the carbonate of sods, and the biborate of sods, or the carbonate of potassium is used, by preference, with the chloride of potassium is used, by preference, with the chloride of sodium, say, about 90 parts of the former to 10 parts of the latter. Into the above-mentioned vessel his mixture is put, and then sufficient heat is applied to the vessel to fuse the material and bring it to red heat. The metal is then submerged in the liquid and allowed to remain a sufficient period of time to thoroughly personate the metal. The metal is, lastly, removed from the vessel and the foreign matter adhering to it dissolved of.—Patent completed.

completed.

2997 W. E. NEWYON, Chancery-lane. Solvers sharpener.
(A communication.) Dated September 30, 1868.

This consists in a bevel-edged circular file combined and arranged with a circular guide-piece, so that on the sharpener being held firmly by the forefinger and thumb of one hand, applied to the edges of a hole made through its centre, or other convenient manner, the blades of the scissors may successively be sharpened by drawing their bevelled sides across the cutting surfaces of the file, while the guide-piece serves to guide the first side of the blade and restrain the latter from slipping off the sharpener.

—Patent completed.

2908 J. H. JOHNSON, Lincoln's Inn. Manufacture of sabile.

Patent completed.

2008 J. H. JOHNSON, Linnoln's Inn. Massufacture of white lead. (A communication.) Dated September 30, 1862.

This scendsts, first, in subjecting metallic lead to the action of carbonic acid gas in a close chamber, and then to a spray of dilute sectic acid, the gas being at such a temperature that a proper degree of heat is maintained within the chamber, without the nue of heating apparatus. The metallic lead, during its process of conversion into a carbonate, is subjected to solutions of chloride of sods and carbonate of sods, while in the same chamber, which is lined with slate, glass, or other material, capable of resisting the sotion of the acids. Second, in the application of the above improvements, in whole or in part, to the Dutch process of manufacturing white lead, by injecting into the spaces within the beds occupied by the pots, steam carbonic acid gas. Third, in producing from the waste products of combustion a pure carbonic acid gas.—Patent completed.

2009 G. A. F. E. DALEYMPLE, Logic, Elphinstone, N.B.

combustion a pure carbonic acid gas.—Patent completed.

2999 G. A. F. E. DAILETRIFIE, Logic, Elphinstone, N.B.
Cupping horse, &c. Dated September 30, 1868.

This consists of a revolving knife or knives, which may
be circular or in the form of segments of a circle. The
knife or knives is or are placed in a metal case, the edges
of which are formed at the front or conting side into teeth
or fingers. These teeth or fingers are blunt at the point,
but the inside edges are sharpened towards the inside of
the case, so thest when the instrument is pushed forward
by the operator, who acids the machine by a handle, the
hair or wood is divided by the teeth and out by the circular
or segmental knife or knives, which revolve on an axis,
sitted with a driving pulley, actuated by a cord or band,
which passes through the handle of the apparatus.—
Patent absandened.

Patent shandconed.

3000 O. W. Powers, Regent street, W. Saving machines. (A communication.) Dated September 30, 1868.

A case or box, containing the necessary machinery for producing the auxiliary power, is fitted beneath the table, and on the ordinary main shaft, which carries the flywheel, there is provided a clutch which alides on such shaft, and arevolves therewith. A pinion, mounted on the main shaft, gears into one of the wheels inside the case, such pinion being loose on the shaft, except when in contact with the slutch. The clutch is worked by any ordinary clutch lawer, which works on a centre in the side or and of the case. This leaves also has an erm, which arrests the transmission of anylliary power when the clutch is moved away from the pinion. The surillary power may ansats of a drum or barrel containing a spring, in combination with which is a ratebet and stop gear, to prevent the spring from being overwound.—Patent shandcomed.

abandoned.

2001 J. WOOLLATT and W. B. DODDE, Gravesend. Moties power. Dated September 20, 1868.

The patentees employ a main lever or beam, rocking on an axis at its centre. To each end of the main lever or beam a connecting rod is jointed, and these rods complet the beam with a combination of bell crank levers and weights, arranged in such manner that the weight at each end of the beam is effective to urge the engine forward during the descending stroke, and is released during the according stroke.—Fatent completed.

2002 G. THENE. Shaffield. Recomment contribles case.

e G. Cuspon, Shattletd. Recopping contridge ages. for a superior se, 1865.

ridge case. One side of this tube has clamping jaws or arms standing out from it, so that the apparatus may be clamped to the edge of a table. Standing out sideways from the upper end of the tube, is an arm carrying a pin, which forms a fulcrum for the end of a lever. The pin passes through a slot in the lever, in order that a projection on the lever may either be caused to bear upon the brass top or base of a cartridge case, piaced within the tube of the apparatus, or else upon the cap which is to be forced down into the recess in the centre of its base. Within the exterior tube of the apparatus is soldered or fixed an inner tube.—Patent abandoned.

2008 B. W. STEVENS, Birmingham. Plobe spindles for losses. Dated September 30, 1868.

This consists in making the said picker spindles or guide bers hollow, that is, of tabes of iron instead of solid bars, and in coating or covering the said hollow or tubular iros spindles or guide bars with gless or enamel. The tubular spindles or guide bars are made from long pieces of iron tubular, made in the ordinary way, and cut into the sequired lengths before being covered or coated with glass or enamel.—Patent completed.

or enamel.—Patent completed.

3004 A. T. BEUES and G. JOHNSON, Birmingham. Measufacture of rouge. Dated September 30, 1863.
This consists in the manufacture of rouge and polishing
powders from waste iron solutions. To the waste iron
solutions, sikalies or alkaline earths are added in sufficient
quantity to neutralize the acid, and precipitate the oxide
of iron from the solution. Soda lime or ammonis are
preferably used for this purpose. After the alkali or alkaline earth has been added to the waste iron solution, it no
longer produces a further precipitate, the solution is
allowed to remain at rest, until the precipitate has subalded, and the clear liquid can be removed by decentation.

—Patent abandoned.

3005 T. FISHER, Little Hord. Supporting rollers for bid

3005 T. Fisher, Little liftord. Supporting rollers for blinds. Dated October 1, 1868.
This consists chiefly in the peculiar construction of a device, which is used instead of the ordinary pulleys and blanks for carrying the pivots of the rollers. The device is constructed with a centre pin or pivot on one side, which is fitted to turn in a suitable bracket or bearing of any convenient form. The other side of the said device is provided with a socket to receive the end of the roller, the centre of the socket being made eccentric to the centre pin or pivot. If desired, instead of the socket, the pulley may be provided with other means for holding the roller eccentrically te the pivots.—Patent abandoned.

he provided with other means for holding the roller eccentrically to the pivots.—Patent abandored.

3006 H. Highton, Brighton. Manufacture of artificial stone. Dated October 1, 1888, This relates to a previous patent, dated June 25, 1888, No. 2048. The block, slab, or slate is first moulded or cast in hydranile mortar or cement, mixed, if desired, with sand, gravel, or other substance, as described in the specification of the patent referred to. Sometimes hair or fibre, or pieces of metal, are mixed with the mortar or cement, to render the articles made from it more tough, and to lessen their liability to break. After the block, slab, or other slate is set, the surface is washed over with a wash prepared with any durable pigment which is able to resist the action of caustic lime. Lamp black, othre, ultramarine, and red oxide of iron, are surfable. The pigment is mixed with lime and water, so as to make a weah of a consistency like that of the Hime wash used for common hime whiting. The proportion of hime to the pigment may be varied according to the tint which it is desired to obtain, but it is best that the proportion of hime should not be less than about one part to one part of pigment. In order to close the pores on the surface of artificial stone, slate, or natural stone, bricks, wood, or other porous substance, so as to render such substance capable of decomposing the silicate and combining with the soda, so as to form an insoluble compound therewith. Bilicate of sods and antimomic acid are thus employed.—Patent completed.

2007 G. T. BOUSPIELD, Brixton. Manufacture of pile fabrics. (A communication). Dated October 1, 1886.

and combining with the sods, so as to form an insoluble compound therewith. Silicate of cods and antimonic acid are thus employed.—Patent completed.

2007 G. T. BOUSTELD, Brixton. Mass/scierc of pile febrics. (A communication). Dated October 1, 1868.

This consists, first, in the production of a tufted fabric wherein the body is composed of feit, and the tufts projecting therefrom are but slightly feited, the tufts being united with the body and forming a part of the fabric by the process of feiting during the felting of the body of the fabric. Second, in producing a tufted fabric whereis tufts which have been introduced in a back of previously manufactured cloth, either woven or feited through perforations in the same, are secured by a process of felting either with or without having an additional back felted to the fabric. Third, in the use of the tuft holder for holding the tufts and supporting the body of the fabric, in combination with the "figgring" apparatus, whereby the tufts and body of the fabric are properly prepared and felted together. Fourth, in the employment of a "tufting punch" or punches, substantially as hereinbefore described, in combination with a tuft holder in a felting machine, for the purpose of preparing a tufted fabric with tufts from bats. Fifth, in the combination in a felting machine, for the purpose of preparing a tufted fabric with tufts from parase or revings. Bighth, in the combination of appliadrical tuft holder, the tuft unches the plaiter, and preseer plate, in order to prepare a tufted fabric with tufts from bats. Seventh, in the employment of one or more tufting needles in combination with a tuft holder is a felting machine, with the tuft holder, the tuft punches the plaiter, and preseer plate, and tufting punches, with the mechanism described for operating the devices in order to prepare a tufted fabric with tufts from parase or revings.—Ferent completed.

2008 J. D. Soller, preseer plate, tufting needles, and their feeding mechanism described. Tenth, the combination of a

rovings.—Patent completed.

2008 J. D. SCALLY, Burton-on-Trent. Filling casks.

This sensists of a bung or stopper fitting into the bung-hele of the cask, and having a finnge or lugs upon it to sessition. This bung or stopper also has two tubes passing through it. The beer or liquid is admitted to the cask through the larger of these tubes, and the other serves for the engage of the air from the cask. By means of a familie sipe of sufficient length to allow the apparatus to be maddly fixed in the cask and ramoved therefrom, the

larger tube is connected with a cock, by which the beer is withdrawn from the supply tank or vessel from which the casks are to be filled. The air pipe also, by a flexible connection, is coupled with a stand pipe fixed to the cui-ride of the tank or vessel, and rising above the level of the liquid therein. The apparatus being fixed in the cask, and the bung or stopper fitting the bung hole sirright, the cock is turned on so that the beer or liquid may pass from the filling tank or vessel down the larger tube into the cask, and this it does so long as the air can escape from the cask up the air tube, but as soon as the ead of the air tube is covered by the liquid in the cask the flow is stopped.—Patent completed.

flow is stopped.—Patent completed.

3009 J. F. G. KROMSCHREIDER, Camden Town. Generating displanemable gen. Dated October 1, 1868.

Clookwork is employed to give motion to an air-foreing apparatus, which forces atmospheric air into a chamber forming part of the same apparatus consining a volatile hydrocarbon oil. The apparatus is so arranged that an extansive surface of the volatile oil is exposed to the air. The air is led from the chamber by a flexible pipe or otherwise to the burner or burners at which it is to be burner, and by a stop-cook the size of the flame is actuated. The clookwork is 'actuated by means of a spring which operates through a funce so as to maintain a uniform action as the tension of the spring varies.—Patent completed.

2010 J. MURRAY and O. HARLING, Keighley. Consuming smoke. Dated October 1, 1868.

This consists in the application and use of a fan placed in any convenient part of, or in connection with, the fine leading from the boiler or furnace to the chimney, so that it will produce a draught to draw away the smoke and gases therefrom, and force the same through or into water supplied to a tank or vessel placed in the bottom of the chimney or flue. One or more jets of steam are inserted into the flue or pipe leading from the furnace to the fan, and from the fan to the water tank.—Patent abandoned.

and from the fan to the water tank.—Petent shandomed.

3011 D. CRICHTON, W. DONAVAND, and D. CRICHTON Manchester. Looms. Dated October 1, 1868.

This consists in improved arrangements for diminishing the friction of the swells on the shuttle, and for regulating the movement of the shuttle in the process of weaving. To each swell in the single shuttle baxes a supplementary spring action, or its equivalent, is applied for steadying the shuttle when in the boxes, and certain mechanical movements put in operation by the working of one of the crank arms of the lathe are also employed for the purpose of taking off the stop rod pressure from the swells shortly before the shuttle is ejected from the boxes by the pickers. The action of the supplementary spring is to keep the shuttle steady in the box by slight pressure at the time the main pressure is withdrawn from the swells to receive the picker stroke, and also to regulate the action of the shuttle across the race board, and at the same time to allow the required pressure to be given to the swell when the shuttle arrives in the opposite box.—Patent completed.

3012 C. B. CHARDON. King William-aircest. E.C. Less.

completed.

3012 C. B. CHARDON, King William-street, E.C. Lassscotice engines. Dated October 1, 1868.

This consists in constructing the drawing wheels of
locomotive engines with projecting pieces fixed to their
peripheries at equal distances assumder. It is proposed to
couple the front and back driving wheels together by
toothed gearing, and also, if necessary, to fix springs
between each of the aforesaid projecting pieces. The
springs, which are formed endless, nearly fill the space
between one projecting pieces and the next, so that the
outer cerface of the said spring describes a circle with the
ef-resaid projecting pieces, and is flush therewith.—Patent
abandoned.

3014 J. OLIVIER, Paris: Motive power. Dated October 1,

1868.
This relates to the use of the wind as a motive power. The wheel or motor upon which the wind acts is formed with vanes, belicoids, winding surfaces, or inclined planes, more or less in number, according to the size of the wheel, and so arranged as to utilize as completely as possible the motive power of the wind. These vanes are attached to a vertical main driving shaft by two or more horizontal plates keyed on the shaft, or by a suitable number of arms.—Patent abandoned.

horisontal plates keyed on the shaft, or by a suitable number of arms.—Patent abandoned.

2015 A. TRORPR, Codnor. Chairs and cages for sales.
Dated Cotober 1, 1868.

The improved chair, cage, or hoist is provided at each side with a perpendicular bar. To each of these bars, near their upper and lower ends, are secured the usual cilp plates or shoes which slide upon the ways or guide rods of the mine or lift above the upper clip plates. On each side of the cage is a pair of cams, or their equivalent, and between these cams, or, their equivalent, the guide rods of the mine or lift ile. To each corner of the cage is attached a strong chain; these chains are connected together above the top of the cage by a ring, to which is attached a fifth chain lying over the centre of the top of the cage. To this short chain is secured the centre of another chain, each end of which is passed through one or more holes in the top or cover of the cage, the ends being secured to two bars, or to an open link, the lower ends of which are hinged upon a short bar which is passed through the curied end of the lower plate of a flat compound spring composed of several plates overlying each other. This spring is firmly secured at the centre of its length to the under side of the top or cover of the cage, and upon the outer ends of the short horizontal bars. At each end of the spring are fastened short levers, having their opposite ends working upon pins in the casms or their equivalent. The ring attached to the chains before mentioned is suspended to the hoisting chain or rope by means of two hooked plates which lie between two other plates.—Patent completed.

2018 W. E. NEWYON, Chancery-lane. Decreticating gross. (A communication). Dated October 1, 1868.

completed.

2016 W. E. NEWTON, Chancery-lane. Decertioning gross. (A communication). Dated October 1, 1868.

This consists in the employment of a new process for moistening or softening the outer cuticle of grain. An alkaline solution is employed, which consists of caustic soda dissolved in water in the proportions of about 1 part of soda to 20 parts of water.—Patent abandoned.

2017 W. B. LAKE, Southampton-buildings, W.C. Deer premes for furnaces. (A communication). Dated October 1, 4868.

This consists in constructing furnace door frames of steam boliers by turning the boiler plate inward and the furnace plate outward, and lapping and riveting the two plates tegether.—Patent completed.

2018 F. A. CALVERT, Manchester. Cleaning wools, &c. Dated October 2, 1868.

This consists, first, in the arrangement of burr cylinders and fluted guards, in combination with their respective brushes, for lifting the uncleaned fibres from the surface of the grate and carrying them back to the burr cylinder or cylinders. Second, in an improved mode of constructing toothed wire cylinders; and, lastly, in improved apparatus for grinding wire or toothed cylinders.—Patent completed.

ratus for grinning wire or toothed cylinders.—Patent completed.

3019 G. Holdbort and W. N. Dack, Manchester. Steam engises. Dated October 2, 1888.
This relates to a patent, dated December 11, 1867, No. 3512. In the present invention, the differential stop is connected to an eccentric rod or its equivalent, thereby causing the former to slide backwards and forwards with the latter. The eccentric may be set opposite to the crank by placing a plate, or having a facing with ports between the slide valve and the expansion valves. The invention further consists in varying the point of cut off by means of lever, one end of which is attached to, or in connection with, the spindle of the cut-off valve, or with the valve and the other end fixed. This lever passes between jaws on a sliding block. The invention also relates to the governor rod, which is made in two parts, each with a head acted upon by springs contained in a box where the variable stop of expansion gears, is in contact with the stops connected to the valve spindle or eccentric rod.—Patent abandoned.

Patent abandoned.

4020 J. F. and S. Jehrins, Birmingham. Eleme halt.
Dated Cotober 2, 1868.

The body of the link consists of a plate or bar of metal, at one end of which is fixed a vertical pin, the other end being provided with an inclined groove or channel in which there is a hole or aperture perforated through the end of the plate or bar. A movable tongue, consisting of a bar of metal, the two ends of which are bent at right angles to its length, is mounted, by means of a suitable collar attached to or formed at one end of it, to the vertical pin, on which it is free to move horizontally, as on a pivot, until it is brought at right angles to the main plate.—Patent abandoned.

plate.—Patent abandoned.

3021 E. O'CONNELL, Greenwich. Feeding bottles. Dated October 2, 1868.

This relates to previous patents, dated April 25, 1858, No. 987, and October 6, 1859, No. 2274. It consists, first, in attaching to the joint at the end of the elastic tube leading from the bottle, a short flexible tubing of suitable diameter, either open at the extremity, or closed, to act as a valve, over which said tube an artificial test is placed. Second, in placing inside the cap or covering that fits over the neck of the bottle, a washer of india-rubber, or other suitable material, through a hole in the centre of which the elastic feeding tube passes, the material around the said hole having several radial slits made therein. Third, in making a shield or mouth guard of india-rubber or other elastic material. Fourth, in making around the said neck a series of rings, in order to cause the cap or cover to hold more firmly to the neck of the bottle.—Patent abandoned.

3022 A. MONENBERGUE, Paris. Kuns. Dated October 2,

3022 A. MONSNERGUE, Paris. Kilns. Dated October 2

1868. The improved kiln has a central fireplace, surmounted by a chimney, which may be heated by wood or by coal, and the fire of which may be constant or intermittent. The kiln has four independent compartments. In burning the material in the first compartment, the fire passes to the second, until the operation in the first is completed, and then air conduits above and in front of the kiln are opened, to cause the heat to spread in the other compartments where the burning or baking has already commenced. Of these four compartments, three are always full, and the other being charged or empited, this latter being separated from the fire, by means of dampers placed before the heat and smoke conduits.—Patent completed.

before the heat and smoke conduits.—Patent completed.

323 N. Histwoon, St. Germains. Moving and reaping.
Dated October 2, 1868.

A cutting wheel or circular saw plate is mounted so as
to work horisontally close to the ground against the standing crop. The saw is keyed to a vertical shaft working in
autitable bearings, and receiving rotary motion, by means
of 2 horisontal shaft and bevel gearing from the driving wheel of the machine. The cutting may be effected
either by means of a fine toothed saw, or by providing
fingers arranged in a semi-circle through which the larger
toothed saws would pass. At the upper end of the vertical
shaft is keyed a pinlon, gearing with an internal toothed
wheel keyed to an inclined shaft placed above the vertical
shaft before mentioned, and carrying a set of rakes to
which rotary motion is transmitted from the vertical shaft,
by means of the rack and pinlon before mentioned, for
laying the corn or grass in sheaf or swath.—Patent completed.

See4 R. F. Drury and J. E. and W. J. WALKER, Sheffield. Ratchel and crunt braces. Dated October 2, 1868. This consists principally in the application and use to and in crank and ratchet braces, lathes, and other tools or apparatus requiring "centres" or pivots of rotation of loose centres in lieu of fixed centres with the object of reducing friction, and thereby increasing the durability of the "centre." The improved "centre" may be made of steel, gam, or other suitable hard metal, alloy, or mineral substance; it is double pointed, the inner point being free to rotate in a female centre, either fixed or movable.—Patent completed. completed.

completed.

2026 C. E. BROGEAN, 166, Fleet-street, E.C. Hardening fatty matter. (A communication.) Dated October 2, 1825. This consists in the hardening of the fatty body incompletely; in the hardening of fatty matters which have first been more or less deprived of solid fatty matters; in the uninterrupted stirring or working up of the fatty matters to be hardened, and of the alkaline lyes until the end of the reaction; in the manner of making the reaction with quantities of lyes than 44 volumes, with the lyes boiling at 572deg, to one volume of fat; in the mixing of the fatty matter and the lyes at a temperature lower than 572deg.; in the treating of the mixture until the disengagement of hydrogen ceases, or until this disengagement in nearly terminated; in the destruction by calcination of the organic bodies contained in the lyes which have been used, and in afterwards recausitiying them for use again; in the regeneration, by means of lime of the alkalies contained in the soap, in place of them regenerating, by previous conversion into sulphates or chlorides according to the Leblanc-progress; in the transformation of the soluble poaps into calcarrons scape, under the missence of heat

and under pressure to facilitate the formation and separa-tion of the calcareous soap; in the employment of the residues of impure lyes for the manufacture of soft soap; in the employment of the calcareous hardened soap for the calcareous saponification of greases and fats; and in the application to the manufacture of candles, soaps, and colours of the fatty acids hardened and produced by the means referred to.—Patent completed.

means referred to.—Patent completed.

3027 T. C. Parson, jun., Bristol. Skates. Dated October 2, 1868.

The skate is fixed to the heel of the boot, by means of a movable lever attached to the end of the sole plate, which rorces the heel into fixed spikes, secured at the back of the heel plate, and is adjustable to any size. The sole plate is fastened by lateral movable stays, which can be adapted to any width. Attached to these is a leather band and buckle mossing over the foot, whereby, without any pressure, the skate is kept firmly in place. The sole and heel plates may be constructed in one piece, and made of any metal or wood.—Patent completed.

3028 E. F. Rose Provin France. Proving and pathing

any metal or wood.—Patent completed.

3028 E. F. Rosz. Provin, France. Breaking and pessing fax. &c. Dated Cocher 8, 1988.

This consists of a shaft on a forked rod, governed by loce and fixed pulleys. There are stripping or pealing rollers, which receive the substance from a grooved steel blade, placed horisontally between the uprights of the frame. Grooved rollers are placed before the blade, which are destined to peel and strip the filamentous substance, before it is subjected to the action of the blade. Three couples of rollers are made use of, which serve to break or crush the hemp or fax, and to deliver it to the peeling or stripping rollers. The rollers which command the other rollers receive motion from the eccentric shaft, by means of gear wheels.—Patent abandoned.

3029 J. SHEIMFTON, Redditth. Packing seedies. Dated.

3029 J. Shrimpton, Redditch. Packing needles. De

3029 J. Shrimpton, Redditch. Packing media. Dated October 3, 1868.

This consists in enclosing needles within the hollow or tube which is ordinarily pierced through a reel, upon which cotton, thread, or other sewing embroidery, or similar material, is sold. In adapting the reel to this purpose, the hollow or tube must be rendered impervious to damp, to effect which it is lined with paper or thin metal. One of the open ends of the hollow or tube is covered by a label, and prevents the escape of the needles at that end, whilst the other end is closed by a removable cap, made by proference of thin metal, attached by a single pivot or pin to the reel. The cap is formed with a small stud, to enable the cap to be turned by the finger upon its pivot, so as to answer that end of the tube, when it is required to insert or to take out a needle.—Patent completed.

\$000 J. Baker. Liverpool. Cleaning this bottoms. Dated

3030 J. BAKER, Liverpool. Cleaning ships' bottoms. Dated

3030 J. BAKER, Liverpool. Cleaning ships bottoms. Dated October 3, 1868.

This consists in a peculiar rotating brush, and in scrapers fixed spirally round a cylinder of wood or other suitable material. A cylinder of wood or other suitable material, asy about 6in. in diameter, and 6ft., or any other suitable length, is taken, and on this cylinder the piasasva or other fibre is fixed in rows of bristles, forming the brush. These fibres are preferably carried round the cylinder in a spiral form, parallel to each other. One end of the cylinder is formed, say, about 1ft, tapered or conical. The end of this is inserted into a truncated, conical, or cylindrical ferrule, to which is attached two, three, or any other required number of oblique blades, and the outer ends of the socket piece are fitted with a swivel, to receive a rope, to allow the cylindrical brush to rotate, when the same is drawn through the water or in a stream.—Pastent completed.

3031 J. ROGERS, Brooklyn, U.S.A. Reviews boxed black.

stream.—Patent completed.

3031 J. Rogers, Brooklyn, U.S.A. Reviving bone black.
(Partly a communication). Dated October 3, 1868.

This consists, first, in the after treatment of the exhausted bone black or animal charcoal, by neutralizing any excess of lime present, by the use of a solution of the superphosphate of lime. Second, in removing any excess of organic matter present in the exhausted bone black, by steeping it in a solution of nitrate of ammonia, and then reburning it.—Patent completed.

8032 D. WEST, Euston-square. Press. Dated October 3.

1868.

This consists in making both the bed and follower between which the bale of goods is to be compressed with concave surfaces, in order to mould the top and bottom of the bale under pressure to nearly the convex form, which the bale is desired to assume when taken from the press.

—Patent completed.

the bale is desired to assume when taken from the press,
—Patent completed.

3033 B. E. B. NEWLANDS, Charlton. Manufacture of
manure and salts of ammonta. Dated October 3, 1868.

This consists, first, in taking any organic matter containing nitrogen (such, for instance, as dried blood,
woollen waste, or leather clippings), and treating it with
vitriol or sulphuric acid, at an elevated temperature of
from about 300deg. to 400deg. Fab., and allowing the
mixture resulting to digest until the organic matter has
been thoroughly acted upon, and converted into a black
mass. To the substance resulting, native carbonate of
magnesia or magnesium (limestone, by preference), is
then added, in a state of fine division, so as to neutralize
the excess of acid. Second, in utilising the nitrogen contained in the impure sulphocyanide of ammonia
contained in the solution, and the ammonia it contains
distilled. This collected in an acid, such as sulphuric acid.
The sulphur cyanide of calcium remaining in the dissulphent and the sulphocyanide of calcium, the sulphuric acid.
The sulphur cyanide of calcium remaining in the dissubjected to dry distillation, and the ammonia evolved is
collected in an acid, by preference, sulphuric acid. The
invention further relates to, the conversion of the nitrogen
the purification of coal gas into ammonia, by dry distillation, either with salked or dry lime, as the case my
sube.—Patent completed.

3034 E. A. Cowper, Westminster. Manufacture of iron
and steel. Dated October 6, 1868.

be.—Patent completed.

8034 E. A. COWPER, Westminster. Manufacture of tron and steel. Dated October 6, 1868.

This consists of an improved apparatus, consisting of a float of cast iron, wrought iron, steel, clay, glass, glass of iron, or other refractory material, so formed as to retain or hold any chemical desired, to be applied to the iron or steel in a melted or semi-melted state, in order that such float may be set floating on the iron or steel, with the chemicals attached/or held to its underside, thus exposing a considerable surface of the chemicals to the iron or steel. The floats may be made of various forms, but a flat plate, with the edges turned down and roughened below, or with

with slight projections, to hold the chemicals wery well.—Patent completed.

wery well.—Patent completed.

3065 J. HOWDEN, Glargow. Preventing escape of heat Dated October 5, 1868.

The vessel or surface to be protected is surrounded wholly or partly by an envelope of sheet iron, wood, or other suitable material, placed at a distance apart from the surface equal to the thickness required for the son-conducting material. The placeter of Paris or similar substance is then made up in its liquid state, and run or poured into the space between the envelope and surface of the vessel until the space is filled.—Patent abandoned.

\*\*Acces B. Harryman and D. Harr. Manchester. [Riliston.]

2026 I. HEILMANN and P. HAIT, Mauchester, Utilizing chemical supports. Dated October 5, 1868.

For the purpose of absorbing certain fumes arising from chemical operations, the exides of calcium or magnesium or the carbonates of these exides are employed, either in solution or while suspended in water, any form of apparatus being used which may be found suitable; or the exides or their carbonates are used in the solid form, and enclosed in suitable vessels in the same way that metallic exides are commanly used for the purification of coal gas.

—Patent completed.

8037 J. B. JOYCE, Bradford. Values and couplings. Dated

3037 J. B. JOYOE, Bradford. Values and couplings. Dated October 5, 1868.

This relates, first, to means of setting or edjusting and working or operating those values of steam engines known as expansion or cut-off values, directly from or by the governor. The value employed is in two parts, one to each port, at the back of the ordinary slide values, which are attached to the value end by right and left handed sornew threads theseon. The rod is in two parts, jointed between the two parts of the value by a coupling. This coupling is in two parts, divided longitudinally; the interior is formed to fit on the rod, and the exterior slightly conical or tapering towards each end, from the middle thereof, and having a screw thread cut thereon. A screwed nut is fitted upon each end of this coupling, so that when the coupling is applied across the joining ends of the two parts of the rod or shaft these nuts can be scarred up. Second, to means of joining together lengths of mill shafting, bars, or piping of metal, or other material, and consists in the application of the hereinbefore described construction of couplings for such purposes.—Patentahandoned.

3068 W. R. LAKE, Southampton-buildings, Chancery

3068 W. R. LAKE, Southampton-buildings, Chancery inc. Chandeliers. (A communication.) Dated October 5

lane. Chandelier. (A communication.) Dated Ostobar's 1868.

There is attached to the top piece, in which indixed the ring or hook for suspending the chandeliers, a central rod, and closely coiled helical springs, three or more in number, are also attached at anitable points, beyond the said rod, and at equal distances therefrom. The bottom part of the chandelier, to which the lamps, candles, holders, or burners are attached, is provided with a vertical tubular stem, which surrounds the rod, and which depends from the top part. The long helical springs before named are attached to the bottom part of the chandelier, and are so proportioned to the weight of the bottom or movable part of the chandelier, that when such part is located about half way between its extreme points of movement, these is equilibrium. On the top of the chandelier tube a piece, serving for the fulcrum of a lever, is secured, one arm being perforated with a bole a little larger than the diameter of the rod before mentioned, while the other arm receives at its send a string, chain, or other means by which the position of the lever may be changed.—Patent abandoned.

8039 C. B. GALAND and A. SOMMERVILLE. Birmingham

changed.—Patent abandoned.

9039 C. B. GALAND and A. SOMMERVILLE, Birmingham Repeating freezems. Dated October 5, 1868.

In this invention both the revolving barrel or cylinder and fixed barrel are made capable of a sliding motion upon a rod, projecting axially from the face of the break-off or false breech of the pistol. Between the break-off and the rear end of the revolving barrel or cylinder a disc is placed, which has a series of holes in it, equal in number to the chambers of the barrel or cylinder. These holes are chambered out to receive the rims of the cartridges when the latter are placed in the chambers of the revolving cylinder. To the axis of the said disc a tube is fixed, which tube slides upon the axial rod hereinbefore described. The revolving barrel or cylinder is situated on and is capable of sliding upon the tube of the disc, the said revolving cylinder and tube being connected together by a sliding key on the said cylinder, working in a longitudinal elot in the said tube. By this arrangement the rotary motion which is given to the disc is communicated to the revolving cylinder.—Patent completed.

#### APPLICATIONS FOR LETTERS PATENT

Dated April 6, 1969.

1083 G. T. Bousfield, Loughborough Park, Brixton.

nprovements in the manufacture of paper, and in sizeing

Improvements in the manuscount thereof.

1034 G. T. Boussield, Loughborough Park, Brixton. Improvements in the construction of shafts and other

thereof.

058 G. Ashcroft, Alexandria, Egppt. Improvements bardenilla Dresses.

1058 G. Ashcroft, Alexandria, Egppt. Improvements in hydraulic presses.

1059 W. H. Balmain, St. Helen's Lancashire. Improvements in the preparation of certain oxidizing agents, and the use of such agents for the preparation of chlorine for bleaching, for yielding oxygen, and for other useful pur-

poses. 1060 L. Mond, Farnworth-within-Widnes, Lancashire. Improvements in utilizing products arising from soda and

otash waste. 1061 W. E. Newton, Chancery-lane. Improvements in

steam generators.

1062 W. T. Eley, Gray's Inn-road, Middlesex. Improvements in the construction of cartridge cases for breech-loading firearms.

1063 C. E. H. C. Healey, Strand. Cleaning breech-loading firearms.

Dated April 8, 1869.

1064 J. W. Warman, Mariboro-street, Farringdon, Berks. A reduction of the distances apart of the levels of the manuals of an organ, so that the distance from one manual to that next it need not be more than two inches. 1065 J. I. Stassen, Euston-road, Middlesex. Improvements in the construction of velocipedes.

1066 A. H. Brandon, Rue Gaillon, Paris. An improved composition for joining leather and rendering it impermeable, more particularly in its application to driving beits, and in certain improvements in the pulleys for such belts.

1067 H. Parslow, Glasgow. An improved appliance to e used in designing the forms of certain parts of articles

be used in designing the forms of certain parts of articles of apparel.

1088 A. Stewart and J. Wotherspoon, Coatbridge, Lanarkshire. Improvements in machinery for cutting metal tubes, pipes, cylinders, bars, or similar articles, and for facing the ends or fianges thereof.

1069 R. W. Munro, Clerkenwell-green, Middlesex. Improvements in markers for whist and other games.

1070 J. Pattison, Newcastle-on-Tyne. Improvements in utilizing the ammoniacal skimmings obtained in galvanizing iron.

ing iron.
1071 D. and G. Hallas, Leeds. Improved apparatus for

1071 D. and G. Hallas, Leeds. Improved apparatus for regulating the supply and for purifying gas. 1072 J. A. Chaulourier, Paris. A new or improved continuous self-feeding cotton gin. 1073 A. Fryer, Manchester. Improvements in the employment of apparatus used in the production of sugar from sugar cane or beet root, and in the construction of parts of the apparatus connected therewith. 1074 W. T. C. Pratt, Newport, Monmouthshire. Improved apparatus for signalling on railways.

Dated April 9, 1869.

1075 G. D. Hughes and A. H. Sellers, Nottingham.
Improvements in self-acting safety valves for steam

1076 J. Aspinall, Harrow, Middlesex. Improvements in

1076 J. Aspinall, Harrow, Middlesex. Improvements in the construction and protection of telegraphic cables, and in machinery for the manipulation of the same, part of the invention being applicable also to the preservation of vegetable substances from marine minerals.

1077 W. A. Hunter, Southport, Lancashire. Improvements in apparatus for lighting street and other lamps. 1078 T. Culpin, Reading, Berks. Improvements in resping and mowing machines.

1079 J. A. Miller, Southampton-buildings, Chancerylane. Improvements in the construction of steam bollers, and in means for removing sediment and impurities therefrom, and in the method of introducing feed water thereto, part of such improvements being applicable to surface condensers.

surface condensers.

1080 J. Denis, Rue St. Louis en l'Ile, Paris. An improved machine for cutting, dividing, and turning straight and conical cogs of wood or of metal without displacing the coursel.

and conical cogs of wood of or mosal without any method the cogwheel.

1081 R. J. Morison, Mark-lane, City. Improvements in pressers for compressing and packing cotton, wool, hay, hides, and other fibrous and plastic substances.

1082 R. J. Colls and A. E. Bull, Reading, Berks. Improvements in fastenings for boots, shoes, and other asticles.

articles.

1083 J. Dewar, Kirkcaldy, Fifeshire. Improvements in treating certain substances for food and for manure.

1084 C.J.F. Campbell, Camberwell, Surrey. Improve-

ments in the means for hanging pictures, looking-glasses,

and other like articles.

1085 C. Lungley, Greenwich, Kent. Improved means of, and apparatus for, removing deposit from tubes, flues, of.

of, and apparatus for, removing deposis and passages.

1086 W. W. Hooper, Bow, Middlesex, and J. D. Hooper, Woodford, Essex. Improvements in the construction of vehicles, and in the means of propelling the same.

1087 W. E. Newton, Chancery-lane. An improved means of, and apparatus for, obtaining motive power for driving various kinds of light machinery.

1088 A. V. Newton, Chancery-lane. Improvements in rotary engines, pumps, and meters.

1089 T. H. Blamires, Huddersfield. Machinery or apparatus for receiving and registering, or indicating, votes at elections.

elections.

1090 W. R. Lake, Southampton-buildings, Chancerylane. Improvements in paper, woven fabrics, and other porous substances, and in the treatment thereof, whereby the same are rendered waterproof.

1091 P. Jensen, Chiswell-street, Finsbury-square, City. Improvements in centrifugal and other pumps, and in syphons.

Dated April 10, 1869.

1092 H. W. Lobb, Sackville-street, Piccadilly. An

Dated April 10, 1889.

1092 H. W. Lobb, Sackville-street, Piccadilly. An improved velocipede.

1093 S. F. V. Choate, Boston, Suffolk, Massachusetts, U.S.A. Certain improvements in firearms.

1094 E. Brasier, New Cross, Surrey, and J. E. Hodgkin, West Derby. Improvements in machinery for scutching or cleaning flax or other vegetable fibres.

1095 W. Smith, Heywood, Lancashire. Certain improvements in looms for weaving.

1096 H. A. Bonneville, Sackville-street, Piccadilly. Certain improvements in sewing machines and their shuttles, and in attachments to sewing machines for sewing different seams and fancy stitches.

1097 W. Ashton and J. H. Storey, Manchester. Improvements in apparatus for ascertaining and indicating the duty of steam engines, modifications of the said apparatus being also applicable to other purposes.

1098 J. Hynam, Deptford, Kent. Improvements in apparatus for the manufacture of crucibles and jother hollow articles from plastic materials.

1099 J. M. Hetherington, Manchester. Improvements in machinery for combing cotton.

1100 J. B. Spence, Manchester. Improvements in the treatment of cast iron for its conversion into malleable iron or steel.

on or steel.

1101 P. Headridge, Lime-grove, Manchester. Improve-ents in dentistry for expanding the upper and lower ments in dentistry for expanding the upper and lower maxillary. 1102 D. B. Peebles, Edinburgh. Improvements in gas

meters.

1103 E. C. C. Stanford, Glasgow. Improvements in applying, treating, and utilizing materials for deodorizing solid, liquid, and gaseous matters.

1104 G. Haworth, H. Haughton, and R. Gibbons, Blackburn. Improved apparatus for facilitating the consumption of smoke.

1105 O. Vivier, Sekforde-street, Clerkenwell, Middlesex. Improvements in escapements for watches and other time-nices.

Improvements in escapements for watches and other timepieces. 1106 J. H. Johnson, Lincoln's Inn-fields. Improvements
in apparatus for removing hair from skins.
1107 J. Parry and R. Morris, Cambrian Slate Works,
Llanberis, Carnarvonshire. Improvements in saws for
cutting slate, stone, iron, or other metal or materials.
1108 E. T. Hughes, Chancery-lane. An improved
dtitch for sewing or stitching together straw, braid, or
similar articles, and machinery for making the same.
1109 W. Martin, Manchester. Improvements, in the
construction of ships and vessels.
1110 L. J. Crossley and R. Hanson, Halifax. Improvements in valves for regulating the discharge of steam,
air, or other elastic fluids.
1111 J. Wadsworth, Bromley-street, Manchester. Improvements in lighting fires and economizing fuel, and in
apparatus therefor.
1112 D. Johnson, Wrexham, Denbighshire. An improved mode of, and machinery for, manufacturing flour,
1113 J. H. Dales and J. F. Maygrove, Wood-street, City.
Improvements in the mode of, and in looms for, weaving
hair cloth and other fabrics.
1114 A. M. Clark, Chancery-lane. Improvements in
fountain pens.

fountain pens.

Notice.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post office MoneyOrder should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

### MECHANICS' MAGAZINE.

LONDON: FRIDAY, APRIL 23, 1869.

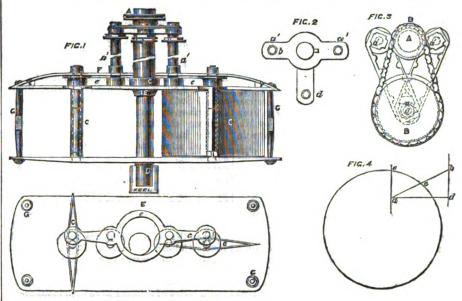

#### DR. LIVINGSTONE.

AST Christmas the scientific world indulged in the fond hope that the veteran explorer, Dr. Livingstone, would then be once more among them. Nor was this hope confined to men of science only. Such is the respect the name of Livingstone universally inspires, that the hope was shared in by all classes of the community, who have come to feel an almost personal interest in the welfare of one who has endured so much in the cause of science. The hope, however, proved delusive, and nearly four months have passed since the time of the great traveller's expected We still, however, lived in constant hope of news, and, only a few days since, everyone read with pleasure the announcement that Dr. Livingstone was at Zanzibar on last New Year's Day, and had left for England viâ the Red Sea and Alexandria. But the pleasure was short-lived; the renewed hopes were speedily dispelled by Sir Roderick Murchison, who received information which entirely contradicted the announcement in question. Sir Roderick has had a letter from Dr. Kirk, at Zanzibar, dated March 5 last, and at that time no news whatever respecting the great traveller had been received for a long period. Judging from his own letters of December 14, 1867, and also from the intelligence derived from Arab traders, it was believed last year that he was proceeding along the eastern shore of the Lake Tan-ganyika, and that, at the place called Ujiji, he would meet with provisions, medicine, and letters, which were sent thither from Zanzibar. But this view can no longer be entertained, for Dr. Kirk states that ivory traders have recently arrived from the very region in question, and had heard nothing of him.

In this dilemma, Sir Roderick Murchison suggests the following hypothetical explanation :- If Livingstone, when at the southern end of the Lake Tanganyika, satisfied himself that its waters were about 1,800ft. above the sea, as stated by Burton and Speke, he would necessarily infer that they could not flow northwards into the much higher equatorial lakes. In this case, he would abandon the northern route in which it was supposed he might find the waters of the Tanganyika flowing into the Albert Nyanza of Baker. Having also ascertained that the Tanganyika was fed by rivers flowing from the south and the east, it would be evident, under these circumstances, that this vast body of fresh water (300 miles in length) must find its way to the west, and he would then follow the river or rivers which issue on the west coast of Africa. Under this supposition, he may be first heard of from one of the Western Portuguese settlements, or even from those

If this view be entertained, we cannot expect to hear of Livingstone for some time to come, as the distance he would have to traverse is vast, and the region unknown. This hypothesis explains why no intelligence whatever respecting him has been received at Zanzibar, inasmuch as he has been travelling through a vast country, the inhabitants of which have no communication with the eastern coast. Whilst, however, correcting the erroneous intelligence, Sir Roderick states that he still entertains a well-founded hope that the distinguished traveller—thanks to his iron frame and undying energy—will issue from Africa on the same shore at which, after a very long absence, he reappeared after his first great traverse of Southern Africa. We trust these hopes may find a speedy realization,

MOODIE'S HORIZONTAL PROPELLER.

#### HORIZONTAL PROPULSION.

LTHOUGH the principle of horizontal A. propulsion possesses several natural advantages which are not common to vertical propulsion, it has not hitherto received that attention which might have been expected in an age when there are so many departures from ordinary rules and systems. Some attempts, we believe, have been made in America to utilize the principle of horizontal propulsion, but with what success we cannot say. At home, Mr. William Moodie has given the subject his careful attention, and has recently laid the result of his experiments and investigations before the Institute of Scottish Engineers. The advantages of horizontal propulsion are, that in smooth water the immersion of the propeller is perfectly uniform, and in rough weather, owing to the proximity of the propeller to the keel, the effect of shocks from the crests of the waves is lessened. Hence, the strains on the gearing rods and the wear of the working parts must be comparatively slight. Should any difference of strain exist on one side more than on the other of the float axles, it will probably be due to a gradual or glid-ing motion of the centre of gyration. The alternate immersion and emersion of the ordinary vertical feathering paddle-wheel causes the resistance, for the time, to be on one side of their axis, thereby producing greater strain on the gearing rods, and abrasion of the working joints, than in the case of the horizontal propeller.

In Mr. Moodie's propeller—of which we annex an illustration—the float motion is produced by spur gear, although, of course, other forms of gearing, such as chain, eccentric or course, tric, or crank rod, could be applied above or below water line to give the requisite motion. This motion is half a revolution of the floats on their axes, for a whole revolution of the propeller. In fig. 1, A is the main shaft of the propeller, carrying a T-shaped bracket, C C are the floats, D the shaft pivot, E the upper arm, F the cover of the gearing case, and G G are cross stays. The arm b, fig. 2, supports the upper ends of the shafts a 1 a 1, on the lower ends of which are cranks, communicating the proper motion to the floats through their connecting rod cc. The floats, being furnished with corresponding cranks, turn their centres perfectly. This motion is

spindle d (fig. 2) are keyed two square pulleys, giving the motion stated. Cranks, however, would perform the same office, and would, we think, be preferable.

We have illustrated the system by a two-

float propeller, and this, in fact, is the form with which Mr. Moodie has experimented, but a propeller of three or more floats could be actuated by the float motion being carried down by a hollow shaft surrounding the main shaft. In sailing alternately with power, the propeller could be uncoupled by a catch box; and even with two floats, would run round easily if the gearing be kept in action, as when propelling, but not otherwise. Two floats, if turned by a hollow shaft, must have a loose crank—out of the line of centres-to their connecting rod to turn them over their centres. The floats are shown with hollow centres, their cranks fitted fast, but the under portion—about two-thirds—revolves on a pivot, which is fast in the bottom plate of the propeller: this arrangement is to give great bearing surface. The correct angle for the floats is 90deg., i.e., any float passing a given fixed point will be at right angles when diametrically opposite.

The theory of this propeller is propounded by Mr. Moodie in the following terms, reference being had to fig. 4 of the engraving :-The column of water acted on by a float a b, is measured in depth by the depth of the float, and in width by the perpendicular distance between  $e\ a$  and  $b\ d$ , viz., by  $a\ d$ . But L a b d is the angle of the float to keelline, and  $a d = a b \times \text{sine } \angle a b d$ . Therefore, the column of water moved by a float is measured by the length of float  $\times$  depth  $\times$ sine  $\angle abd = area(A) \times sine \angle abd$ . Now, with two opposite floats, when the angle abd of one = 0deg., that of the other = 90deg., or one = odeg., that of the other = 90deg., the acting power of the propeller then is equal to A (sine odeg. + sine 90deg.) = A minimum power: and when the angle of one float = 45deg., that of the other = 135deg., therefore, the power = A (sine 45deg. + sine 135deg.) = A  $\sqrt{2}$  (maximum power). In a similar manner, it can be shown, that for a propeller with three floats, at equal distances, the power varies from A  $\sqrt{3}$  to 2 A. And so on, for any number of floats. Since the central pinion on the hollow shaft is only half the diameter of the wheels on the float axles, and prevented from revolving with got by a pitch-chain embracing the wheels
B (fig. 3), the respective diameters of
which, being as two to one—the smaller
one capable of being turned round freely,
and so manœuvring the vessel, by changing
the floats to any desired position or angle to
the keel-line. On the lower end of the

circle either way-or be brought to a stop while the engines go on in one direction. When under canvas only, the floats will act like balanced rudders—when the propeller is working, the steering power is so great that, although the rudder were set to steer straight ahead, the vessel could be canted with no perceptible resistance from the rudder; and as the floats are balanced, there is very little resistance on the steering wheel.

The practical side of the question is represented by some experiments which have been made with the horizontal propeller by Mr. Moodle. They show a large percentage in its favour over the ordinary propeller. They its favour over the ordinary propeller. They were made with a boat of the following dimensions:—Extreme length, 16ft. 5½in.; beam over all, 3ft. 9½in.; draught forward, 1ft. 5in.; draught aft, 1ft. 10in. The dimensions of engine were:—Diameter of cylinder, 3in.; length of stroke, 6in.; boiler pressure, 45lb. The safety valve was blowing off slightly during all the runs. The horizontal propeller had an effective diameter of 10in. The number of revolutions per minute was 140, the distance tried over was 758ft., and average time per run was 2min.; or, at the rate of 4.30 miles per hour. The screw propeller against which it was tried had a pitch of 2ft., the number of revolutions per minute was from 149 to 150, the distance tried over was 758ft. (as with the horizontal propeller), and the average time per run was 2min. 42sec... or at the rate of 3.19 miles per hour. This result shows a clear percentage of gain in favour of the horizontal propeller of 35. The screw was of the most approved form for speed as applied to small craft. The result of these trials unquestionably shows a great advantage in Mr. Moodie's ingenious apparatus over the screw, and should lead to further experiments in the same direction on a larger scale. The only objections that at present appear in view are the wheelwork, and the number of parts in the apparatus. These, however, are points which may be surmounted by practical men in working out the idea. To overcome these difficulties will be to inaugurate a new method of propulsion, for the introduction of which, so far, great credit is due to Mr. Moodie, whose principle we hope to see further developed and applied.

### INDIAN TELEGRAPHS.

"OUR experience of its operations has led us to the conclusion that, for com-Us to the conclusion that, for commercial purposes, it is not of the least use as at present conducted." "Our experience leads us to place little or no confidence in the telegraph office as a means of transmitting messages." These extracts are taken haphazard from a number of opinions expressed by the merchants of Calcutta in 1861 relative the then state of telegraphy in India. They are given as the expression of opinion at that time of Indian telegraphy, which was then held up to ridicule, no confidence being held either in its speed or accuracy, the ordinary postal system being preferred, which, though slow, was sure. With the extent of telegraph then existing, it is a sad picture to look back upon; but, as out of evil comes good, so, out of the wretched system of telegraphy that was then a bye-word, by dint of skilful management and administrative talents, good has come, and the system in India now holds up its head, and may fairly be ranked as standing high in the order of telegraphy. The great changes that have led to this satisfactory result are due principally to the farseeing vision of the late viceroy, Sir John Lawrence. The inherent defects of the sys-Lawrence. The inherent defects of the system appear to have been early grasped by him, and measures taken to improve and extend the system; the result is apparent, and the improvement of telegraphy in India

braced a length of line of 11,350 miles, and a length of wire of 11,661 miles, there being but a slight difference between the two. At the expiration of his viceregal term, 1868, the system consisted of—Length of line, 13,855 miles; length of wire, 22,567 miles. Instead of being nearly similar, the mileage of wire had increased to nearly 2 to 1, the increase during the five years being-Length of line, 2,505 miles; length of wire, 10,906 miles. Such a result cannot but be considered as eminently satisfactory. However, the increase of mileage would be valueless if the increase and improvement of the internal administration had not also been advancing. For, as matters were at that date, an increase in mileage would have had no benefit in restoring public confidence unless the management had largely improved. Such has unquestionably been the case, and the largest share of improvement has undoubtedly been shown during the time the present director-general has held office. In 1865, Colonel Robinson, R.E., from his known administrative talents, was appointed by Sir John Lawrence director-general. The appointment was given to the right person, and a series of reforms have been inaugurated that, when their full force has been felt, will raise the telegraphic system of India probably on a par with the best in the world. It is since Colonel Robinson's accession to office that we have been able to obtain really accurate details of Indian telegraphy, and, from returns compiled under his direction, we are enabled to glance at some of the improvements during Sir John Lawrence's governorship.

First, with regard to the through transmission and the Indo-European telegraph, with which we are most interested. In April, 1865, Colonel Douglas reported the errors on the Indo-European messages contracted in India as amounting to 38 per cent. This amount has been gradually and surely reduced; in 1867 the maximum was 8 per cent., and in 1868 only 4 per cent., this percentage undergoing a gradual reduction to below 2. For the corresponding period, Indian messages show a reduction from 21 per cent. to less than 1 per cent., a result which will compare favourably with that of any telegraph system. During each of these years there appears to be a slight increase of error in the monsoon season, which may be accounted for electrically, and not as the fault of the manipulators. We cannot give statistics of the percentage of errors formerly, but the fact that errors have been reduced as low as 1 per cent. effectually removes the stigma formerly cast upon Indian messages that they "are frequently so distorted and rendered unintelligible that they are not of the least use when received." "Messages are often late, sometimes missing, and rarely correct." That this improvement in accuracy has not been purchased at the expense of speed in transmission, but rather that improvement in speed as well as in accuracy, has been going on, we shall endea-

vour to prove.

We will take the monthly average time of transmission of messages between Bombay and Kurrachee, and Calcutta and Kurrachee, as our first instances:—

BOMBAY AND KURRACHEE.

Date.	Maximum.	Minimum.	Average.
1866.	67	5	17
1867.	21	2	7
1868.	17	1	5

#### CALCUTTA AND KURRACHEE.

Date.	Maximum.	Minimum.	Average.
1866.	51	7	27
1867.	36	8	20
1868.	26	6	11

same period of the year, during the monsoon season, and were it not for the peculiarities of the climate, the average time of transmission would contrast very favourably indeed with telegraphy elsewhere, especially when one considers the distance between the places. In talking of Bombay and Kurrachee, distance seems to have a diminishing effect, and people speak of them as they would of London and Edinburgh; but when we compare the relative mileage, 400 in the latter case, to 1,300 in the former, it will be acknowledged that taking the monsoon into consideration, an average of five hours (we speak in round numbers) during the year is a fair average, and, as compared with two years previously, shows a reduction of more than one-third of the time.

Special efforts have been made to improve the main Indian routes, in connection with European traffic; but that the rest of the Indian routes have also undergone improvement, the following figures will give ample evidence :-

CALCUTTA AND BOMBAY.

Date.	Maximum.	Minimum.	Average.
1866.	38	9	21
1867.	36	9 <del>1</del>	10
1868.	25	8	12

Space does not permit, or other instances of improvement might be shown. We have, however, shown that telegraphy in India has good reason now to be held in respect, where formerly it was held in ridicule. A reduction of errors in India, from 38 per cent. to below 2 per cent. on Indo-European messages, and to less than 1 per cent. on local messages, and an increase in the average speed of messages from seventeen and twenty-seven hours to five and eleven hours, show signs of wonderful progress, and gives results that can be favourably compared with other systems. But, with regard to errors, there is still room for improvement, and we doubt not that when our readers' attention is again called to the question, further improvement will be shown. Our Indian telegraph system is now worked on a good practical basis, and, as its success has been so incontestably proved, its continued success will be shown by still further improvements.

In this respect the term of office of the late Viceroy has been productive of great good, and those people, connected by commercial or other pursuits with India, must acknow-ledge the good that has been done; but, whilst giving credit to the able administration of Sir John Lawrence, we must not omit to give our unqualified praise to the present director-general, who has done so much in so short a time to cause so great an improve-ment. Though, as a rule, objecting to appointments requiring a special technical knowledge being given to one totally without experience or acquaintance of the nature of its duties, &c., yet, in this case, we sincerely believe that the appointment could not have been better made, even if one had been selected who possessed all the necessary

requirements.

During the time Colonel Robinson was in England he made himself thoroughly conversant with the advantages of the various telegraphic systems. The knowledge so obtained has enabled him to keep out of the old Indian groove, and bring Indian tele-graphy to its present highly efficient state; and we trust shortly to be able to report, that, in addition, he has brought it not only to a more prosperous but a remunerative condition.

### THE ROYAL INSTITUTION.

and the improvement of telegraphy in India is daily manifest.

When Sir John Lawrence took charge of India, the telegraph system then (1863) em
The time is given in hours. The time of maximum transmission occurs always at the Temperatures and Animal Life of the Deep

Sir Henry Holland, Bart., F.R.S., d. The lecturer said that until very recently philosophers were strongly of opinion that there could be no animal life in the deep sea, because of the enormous pressure of the water; moreover, as some of the earlier dredgings proved that animal life decreased the greater the depth of the water, a kind of rule-of-three sum was made to show that at very great depths animal life would probably be absent. About fifty years ago, General Sabine saw a starfish brought up from a depth of 1,000 fathoms, in Baffin's Bay, and the fish had some of the green mud of the bottom sticking to it; likewise, in surveying the proposed North Atlantic cable route, via Greenland, a few years ago, H.M.S. "Bulldog" brought up a live starfish from a depth of 1,260 fathoms. It was, however, disputed in scientific circles, whether these fish really came from the bottom or from mid-water. Dr. Carpenter all along was inclined to think that they came from the bottom, because he had studied the habits of starfish in an aquarium, and noticed that they always crawled along the bed of the tank , and never swam. Facts about life in the deep sea have been collected within the past few years by English and American ships, employed by their respective govern-ments to make soundings along all the proposed Atlantic cable routes, from the Azores in the south as far as Greenland in the north. Sir James Ross once made dredgings in Antarctic regions, but, unfortunately, the results were never published Last summer, the Admiralty sent out a ship to make soundings to the north and north-west of the Hebrides, and Dr. Carpenter accompanied the expedi-tion. The result of all these researches is to demonstrate that life is present in the deep sea, that soft fleshy animals can exist where the pressure of the water is 300lb. to the square inch, and that on the bed of the Atlantic Ocean there are now many animals living which geologists and naturalists supposed to be extinct.

The bottom of the North Atlantic Ocean consists, for the most part, of soft white mud, which will be known to the geologist of the future as "chalk." This mud contains many soft sarcodic animals, known as foraminifera and globigerina; they are covered with delicate white shells, and, for the most part, can only be examined under the microscope. In many instances, they have been brought up alive. Sponges also are plentiful on the deep sea bed, but they are remarkable for the siliceous composition of their skeleton framework, and, in fact, belong to a class long supposed to be extinct. As the temperature of the deep sea bed varies considerably, so do the kinds of animal life in different parts of the bed; where the water is warm, animals of the type found in the Gulf of Mexico predominate. Thus, not only is a true chalk formation going on at the bottom of the Atlantic, but in different parts it contains different animals. Sir Roderick Murchison had told the lecturer that till these facts were brought under his notice he should certainly have said that such formations could not have been contemporaneous, had he chanced to meet with similar rocks in his geological studies. When dredging very far geological studies. When droughed north in the Atlantic, the white mud is not always brought up, but sometimes volcanic stones in its stead. It seems as if the Gulf stones in its stead. It seems as if the Gulf Stream spreads out into fingers towards the north, where it meets with cold currents coming back. The motions of these great bodies of water are, however, so slow that they hardly deserve the name of "currents."

As regards the temperature of the water, it was always very nearly 52deg. at the surface, no matter where the expedition of last

minimum thermometer will not go down quite low enough, as all who are experienced in the use of such instruments can testify, and it may be that the pressure of the water upon the bulb at great depths may tend to make the indications rather too high. At all events, in the following tables of results, if the figures err at all, they err in being too high rather than too low:

DEPTHS AND TEMPERATURES OF SOUNDINGS. WARM AREA.

Number of Sounding.	Depth in Fathoms.	Temperature.	
		At Surface.	At Bottom
1		deg. min.	deg. min.
_	500	54.5	49
2	164	54	48.5
3	229	54	48
4	72	54	49
5	62	53	50
12	530	52.5	47.3
13	189	52	49
14	650	53	46
15	570	52	47
16	650		_
17	620	52	46

COLD AREA.			
6	510	52	33
7	500	51	32.2
8	550	53	32
9	170	52	41.7
10	500	51	33
11	450	50	33.2

Sounding No. 9 in the above table was on the top of a bank, which accounts for the difference in the results.

### THE INSTITUTION OF NAVAL ARCHITECTS.

NO papers were read on the important subject of the sheathing of iron vessels, the first by Mr. Grantham on copper sheathing, and the second by Mr. Benjamin Bell on zinc sheathing. One of the chief difficulties the naval architect has to contend with is the sea weed and barnacles, which attach themselves to the sides and bottom of the ship. The builder may lay down the finest lines, and may put the maximum engine power into his vessel; he does his best, and the ship will do well at the measured mile, if the trial is made immediately the vessel is undocked. The speed attained on the trial trip, however, is no criterion of what can be got out of the vessel, when she has been at sea a few months or even weeks. In the official report of the Controller of the Navy on the comparative trial between the "Bellerophon" and the "Minotaur," the fact that the former had been out of dock twenty-one days, while the latter had been undocked only nine days, is particularly referred to as an unfair advantage the one ship had over the other. Mr. Grantham tells us that sometimes a vessel loses as much as half her power from fouling. This fouling has been attempted to be remedied in several ways. Prevention is better than cure, is a well-known proverb; but all attempts to prevent the weed and barnacles from attaching themselves to the ship's bottom, have, so far, signally failed, and it is now universally allowed that the only way to keep the bottom in any degree clean, is to employ some substance which will, day by day, peel off in indefinitely thin layers, and will so allow the ship to change its skin, and

is very dear, for one thing; and, what perhaps is still worse, the copper skin must be kept perfectly sound and watertight. If once the salt water finds it way in through any flaws in the copper, galvanic action sets in. The copper remains clean, and is saved from wasting, but unfortunately at the expense of the iron skin and bolts. The economy is that of the Irishman's, who catches cold by walking with bare feet to save his shoes. walking with bare feet to save his shoes.

Mr. Grantham's paper had reference only to copper as a means of protecting iron ships.

It described a method of coppering vessels, which in its essential points has been used both in the mercantile service and also in the page. It consists of feetening always of It consists of fastening a layer of the navy. wood planking to the iron skin, then another layer of wood to the first, and then over all layer of wood to the first, and then over all the sheet copper to the outer layer of wood. All this is necessary to insulate the copper and the iron. This is a very expensive process, and one which cannot be successful. The straining of the vessel at sea, or its grounding, will soon impair the continuity of the copper and this copy days. the copper, and this once done, the copper is little or no good. We will, therefore, leave the subject of copper sheathing, and pass to Mr. Bell's paper on zinc as a means of protecting iron ships. This metal has, as is well known, with refer-

ence to iron in salt water, exactly the opposite property to that which copper has when immersed in salt water in conjunction with iron. The copper is electro-negative with respect to iron, that is to say, no action takes place on the surface of the copper, but the whole action is on the surface of the iron, which is corroded by the chemical action which is set up. On the other hand, zinc is electro-positive with regard to iron. The zinc is attacked by the chemical action and is wasted away, while the iron is preserved intact. This property of zinc shows us its value as a sheathing for iron ships. It may be fastened on to the iron skin in any of the methods now in use for copper sheathing, with this in its favour,—the zinc sheathing need not be watertight like the copper must; in fact, it ought not to be so. The salt water getting in between the iron skin and the zinc is the cause of the galvanic action, which preserves the iron at the expense of the zinc. The zinc exfoliates, carrying away the weed and barnacles. The intensity of this action can be regulated by the proportion of zinc to iron that is exposed to the action of the water. Zinc has also been used in boilers as a means of protecting the boilers themselves from the action of the salt water, which has passed through the copper tubes of the condenser. The zinc has been found to waste at the rate of more than one inch in a month. Nobody can doubt that the use of zinc as a means of protecting iron vessels, of which Mr. Bell is than the use of copper. We cannot help thinking that zinc must very soon take the place of copper. We shall have to familiarize ourselves with the phrase "to familiarize ourselves with the phrase "to zinc" a ship, and we shall be allowed to forget the one we have been used to for so long "to copper." The zinc is much the cheaper metal, and if it had no other advantage, this alone would decide the race in favour of the zinc over the heavily handicapped copper. Mr. Bell's paper we have thought worthy of a verbatim reprint, and it will be found on another page of our present number.

Professor Rankine contributed a paper on the strains in propeller shafts. Like most of the papers of this gentleman, this one is very full of matter, and is almost incapable of being compressed. We will, therefore, merely mention a few of the points which are discussed in this paper. According to experisummer made the soundings. But at the bottom the temperatures were very different.

At each sounding three thermometers were used, and their indications commonly agreed pretty closely. Sometimes the index of a attended with very many disadvantages. It large taskin, and discussed in this paper. According to experiments, the best wrought-iron axles of very smoothly running railway carriages, at speeds notabove twelve miles an hour, will safely bear to a great extent. Its use, however, is a stress of 9,000lb. to the square inch. But

is sure to be found out in the long run, by a stress of this magnitude. If we take into account only the twisting action of the shaft, the maximum stress in actual vessels on the propeller shaft is found to approach very nearly the value given above. The real in-tensity of the stress is greater. Together with the twisting action, there is always a bending action, produced partly by the weight of the shaft, and partly by its reaction when the vessel pitches, i.e., partly statical and partly dynamical. This bending action should be dynamical. This bending action should be calculated, if we would know the actual limits of safety for the propeller shaft of any vessel. Professor Rankine gave formulæ for calculating these different actions, with numerical examples, and he also gave rules for designing the shaft of a given vessel. We would recommend everyone whose business it is to design large engines to consult this paper. It is important not only to marine engineers, but to the makers of all engines which have large and heavy shaftings. Its author tells us that "it seems probable that if the method of calculation now described were applied to actual examples of propeller shafts, many instances would be found in which the resultant stress reaches, or even goes beyond, the utmost limits consistent with safety."

The resistance of vessels was the subject to which Mr. John J. Thornycroft, C.E., devoted a short paper. The results of some of the most extreme forms of vessels were compared with those estimated by a new formula, which Mr. Thornycroft exhibited, and we must allow that there was a very remarkable coincidence in the velocity of different known vessels as actually obtained and as calculated from this new formula. However, as there are four constants in the formula, which must be obtained by trial, and as Mr. Thornycroft did not expressely tell us that these constants had been obtained from one set of ships, and then the formula applied to another set (namely, those whose calculated and actual performances he compared in a diagram), we cannot at present put any faith in the new

Staff-Commander Bourchier, R.N., read a paper describing a new design for a life buoy, of which he exhibited a working model. If a man overboard is lucky enough to reach a life buoy at present (it does not matter whether it be the annular life buoy of the merchant service, or the cross-shaped one in use in H.M. navy), he has to expend all his energy in holding on. If the water is cold, or the sea rough, this exertion soon becomes too much for exhausted nature, and the man drops off and is lost. This defect is supposed to be remedied in the proposed buoy, which is formed of an airtight double cylinder. This cylinder floats on the water, and carries a light metalwork basket, into which the man over-board, it is hoped, will be lucky enough to climb. Here he will stand with merely his legs in the water, till he is picked up. Of course there are other improvements proposed, such as flags to attract notice in the day time, and signal lights for the nights; but it seems to us, that the essential improvement in the proposed design, is the affording the man whose life is in danger something more than a mere floating mass to cling to.

NOTES ON RECENT SCIENTIFIC DIS-COVERIES AND THEIR PRACTICAL AP-PLICATIONS.

THE ARTIFICIAL PRODUCTION OF ALIZARIN-PRINT-ING ANILINE BLUE ON CLOTH-THE DETERMINA-TION OF SULPHUR IN CAST IRON-THE RECENT EXPLOSION IN PARIS-NEW MODE OF PROCURING

WE have received a little more information on the conversion of anthracene into alizarinalluded to in our last-but not very much. It seems that the discoverers, MM. Graebe and Liebermann, tried the action of powdered zine upon alizarin, and, thy its agency, removed the oxygen

from the alizarin, and reduced it to anthracene. It was natural, therefore, to conclude that, by the oxidation of anthracene, alizarin would be procured. As a fact, it is found much more easy to remove oxygen from a molecule than to get it in; but this, the chemists we have named, have succeeded in doing, no doubt in a roundabout way. for the attempt to oxidize organic bodies directly mostly leads to their complete destruction. Lauth suggests that the desired result may possibly be obtained by, first, converting the anthracene into sulphanthracenic acid, and decomposing this with soda. The resulting product, he says, ought to be either alizarin or something convertible into it by further exidation. Purpurine, the other essential colouring matter of madder, is also converted into anthracene by the reducing action of zinc, and so, it seems, are a number of other vegetable products. Alizarin from anthracene will probably remain a chemical curiosity for some time to come, but, in the end, the discovery may lead to as great changes in the trade in madder as the aniline colours have made in that of safflower, the importation of which has almost ceased.

While on the subject of colours, we may notice a French patent for the production of a solid aniline blue on cloth. What is called aniline black all calico printers know to be only a very deep violet blue, and the inventor who takes out this patent has imagined that by altering the proportions of the re-agents, he can moderate the action, and stop, at will, either at a light violet blue, a blue grey, or a grey. The proportions he gives for the production of the blue are as follows:—
In a litre of water he dissolves 100 grammes of aniline, 40 grammes of chlorate of potash, 3 or 4 grammes of sulphate of iron, 10 grammes of salammoniae, and 60 grammes of an aniline salt—the hydrochlorate or tartrate answering best. mixture, properly thickened, is printed on, and treated just as for the black. How the process succeeds we can hardly guess; but we fancy it will result in a colour, which, if not black, will have little permanence.

Gintl gives a very easy method of determining the impurities in cast iron. It is applied by him to the estimation of the sulphur contained in the iron, but, as will be seen, it is available for the separation and determination of most of the usual The iron is reduced to as minute a impurities. The iron is reduced to as minute a state of division as possible, and is then treated with a strong solution of perchloride of iron, as nearly neutral as possible. The mixture is kept heated for ten or twelve hours, at the end of which time almost all the iron will be found to have dissolved, leaving, as a residue, the carbon, sulphur, phosphorus, and silicium, togother with the little iron left undissolved. This residue has only to be well washed, oxidized, and dissolved, and the sulphur estimated as sulphate of baryta. The exact plan directed by the author is to intro-duce the residue and filter into a porcelain crucible, having, at the bottom, 3 parts of nitrate of potash and I part of bydrate of potash; heat to fusion, dissolve, and precipitate with chloride of barium. The phosphorus and silica will be contained in the same solution, and can be deter-

A report by M. Fontaine, in the "Bulletin de la A report by M. Fontaine, in one School at the mixture which exploded with such frightful results in the Place de Sorbonne, was a mixture of picrate of potash with chlorate. M. Fontaine states that he has been engaged since 1861, with the French War Department, in making experiments with picrates, chlorates, and nitrates, to find a substitute for powder, applicable for torpedoes, quick matches, and other things. He has found to his cost that he has succeeded in producing a most destruc tive compound, and nearly shared the fate of that often mentioned unfortunate—the engineer who M. Fontaine, was hoisted by his own petard. M. Fontaine, almost as unfortunate, suffered vicariously in the person of his son.

mined separately.

Oxygen procured cheaply and easily is, as we have often said, a very desirable thing. The numerous applications that could be made of it are so evident that we need not stop to mention them, but we lay before our readers yet another plan, and this time an ingenious one, for obtaining it. The mineral sources of oxygen being comparately exponsive, MM. Montmagnon and Delaire have betaken to themselves to that cheap reservoir our atmosphere, and have further availed themselves of the discri-

be understood, the figures of the authors we name, without checking them by a reference to the figures of Dr. Angus Smith, who has made most careful experiments on the absorptive action of charcoal. According, then, to our anthors, I(N) litres of fresh wood charcoal will, when exposed to atmospheric air, occlude 925 litres of oxygen, but only 705 litres of nitrogen. Now, it would appear tha when the charcoal so saturated with gas is thoroughly saturated with water, there will be expelled. 650 litres of nitrogen, but only 350 litres of oxygen. Thus we have now left in the pores of the charf coal 575 litres of oxygen, and only 45 litres of nitrogen, that is, oxygen practically pure for industrial purposes. To extract the gases, the authors employ a pump, and they tell us that it again exposed to charcoal, the oxygen will be obtained almost pure. There can be no doubt They give no account of the cost of oxygen; but it is clear that it will be represented chiefly by the cost of the machinery and cost of work-

#### PARLIAMENTARY NOTES.

YESTERDAY week, Mr. Baines, in the House of Commons, asked the Postmaster-General if he could inform the House whether the Telegraph Bill would be prosecuted, and, if so, whether he could state when

The Marquis of Hartington said that he could not add anything to the answer he gave on this subject two weeks ago. The fact was that the arbitrations under the Act of last year as to the sums to be received by the companies were in progress. Some of those arbitrations had been completed, but a large number was still in progress, but when they approached completion, and it was possible to form an estimate of the amounts to be paid, he should be able to state the intentions of the Government. It was intended to-morrow to move for leave to bring in a Bill to enable the Government, if they purchased the property of the telegraph companies, to obtain the monopoly for the transmission of telegraphic messages.

On the following evening, a question, which was asked last session, was again repeated, with regard to the wretched collection of timbers at Waterloo Bridge, and received the same reply. Mr. G. Gregory asked the President of the Board of Trade whether his attention had been called to the piling in the River Thames between the Charing Cross Railway and Westminster Bridges; and whether he could state when it would be removed, or who was responsible for the continuance of it.

Mr. Bright said that was a matter with which no Government department had at present any The piles to which the hon. power to deal. gentleman referred were connected with the works of the Waterloo and Whitehall Railway Company, and that company had time permitted it up to July, 1870, up to which time no person could legally interfere with the piles. After that date it would be in the power of the Board of Trade and the conservators of the Thames to take

steps for their removal.

Mr. J. B. Smith then put a question to Mr. Bright respecting the metric system, in reply to which Mr. Bright said that the state of the law with respect to the use of metric weights was not satisfactory, and nothing could be more absurd than that it was lawful for a man to use a certain description of weights and measures, but that he should be liable to a penalty if they were found in his house and shop. He was surprised that his hon. friend did not take care that the Bill was more carefully worded, in order that his object might be secured. As to the possibility of bringing in a bill during the present session to amend the law, he might tell his hon. friend, what he no doubt knew, that the Standard Commission had reported in favour of the change which he had so strongly, and for so long a time, advocated in the House, and he supposed that some time, when the Government or the Board of Trade had a great deal more leisure than at present, a measure upon the subject might be introduced; but he did not think that there was any probability that it would

Last Tuesday evening, Mr. W. Cowper asked the Secretary of State for War whether it was intended to alter the organization and position of mative action of wood charcoal and water, or the Military Train; and, if so, when the character certain saline solutions. We give here, it must of the intended alteration would be announced.

Mr. Cardwell, in reply, said that a change of that nature was now in course of progress under the Control Department. The warrant directing the constitution of the new corps was now under the consideration of the Commissioners of the Treasury, and as soon as it had received her Majesty's approval it would be made public.

At the same sitting, Mr. Stacpoole asked the Under Secretary of State for India if it was true that her Majesty's transport "Crocodile" lately left Malta for England nearly empty, while General Lysons and other officers and men whom she might have accommodated were waiting for pas-

sage home at the public expense.

Mr. G. Duff said it was within his knowledge that the "Crocodile" came home without any troops on board, but he knew nothing whatever of any application having been made on behalf of General Lysons, or any other officer, for a passage on board that vessel. If an application had been made in proper form, it would no doubt have been complied with. It had not hitherto been the practice to give passages on board her Majesty's vessels to officers and men not entitled to a passage at the public expense, but he thought that in such an exceptional case as the one to which the hon. gentleman had called his attention, that rule might have been departed from.

### LONG AND SHORT IRONCLADS. BY MR. E. J. REED, C.E.

(Concluded from page 275.)

THE last investigation in the paper is purely theoretical, and consists of a determination of the dimensions which would be required in two ships, of which the horizontal sections are curves of sines, and which are prismatic vertically, if they were built with the same weight per square foot of hull (say 1 ton) as the "Bellerophon," but carried twice the weight of armour per square foot (say 6-28ths of a ton). In these cases the bottom is taken to have weight as well as the sides, the speed for both is 14 knots, the draught of water is 25ft., and the depth of the armoured side 24ft. One of the ships is seven times her breadth in length, and the other is five times. Professor Rankine's rule for the calculation of horse power and speed is employed, and the same conditions of engines, &c., are assumed, as have which the horizontal sections are curves of sines. conditions of engines, &c., are assumed, as have been indicated previously. The larger ship carries 1,350 tons additional weight, and the smaller 900

The results obtained for these ships are as follows, when expressed in round numbers:-

	Larger ship.	Smaller ship.
Length	585ft.	425ft.
Breadth	84 ,,	85 ,,
Nominal horse power	1,267 H.P.	980 H.P.
Indicated	8,890 ,,	6,860 ,,
Weight of hull	7,586 tons	5,540 tons
n armour and }	6,124 ,,	4,470 ,,
engines and coals	2,540 ,,	1,960 ,,
" carried	1,350 ,,	900 ,,
Displacement	17,600 tons	12,870 tons

These results are very different in detail from those obtained in the cases based on the actual trials of the "Bellerophon" and "Minotaur," but not greater than might have been anticipated from the adoption of such a different form of ship, and mode of calculating resistance. The 2,000-horse power which is needed by the larger above the power required by the smaller ship, is principally due to the difference between the immersed surfaces of the two ships, and is spent in overcoming friction. The imships, and is spent in overcoming friction. The immersed midship sections, it will be remarked, only

mersed midship sections, it will be remarked, only differ by a very small amount.

This last investigation serves to show that the theoretical best form of ship being taken, and the most recent rule being applied in the calculations, the speed of 14 knots can be obtained in the short type of ship at a surprisingly less cost and size than the long type requires, and this result agrees with that of the preceding investigation based on actual trials.

I will now refer briefly to another aspect in the case of long versus short ironclads. Supposing two ships to be constructed, having the same central, bow, and stern batteries, and the same height of port above water, the same depth and thickness of armour in the water-line belts, the same proportion of weight of hull to total surface, and the same equipment and armament, with engines of the same type, and with weights of coal which would enable them to proceed equal distances at the same speed, would the advantage, on the whole, rest with the ship which had the form and proportions of one of our long ironclads (say the "Minotaur"), or with the ship having more moderate proportions (say those I will now refer briefly to another aspect in the ship having more moderate proportions (say those f the "Hercules")?

It will be obvious that this is a different case from those considered in the Royal Society paper, and one in which the disadvantage of the long ship as compared with the short ship is not so great as in compared with the short ship is not so great as in those cases. In the wholly armoured ship in pass-ing from a short to a long ship we increase the armour very largely; while in the case now about to be discussed we propose to lengthen the belted portion only, and, therefore, get the benefit of length with a less burden of armour. Still, we shall see that, even in this case, the short ship is to be

preferred to the long.

I have taken the "Hercules" as the representative short ironclad, and have used the known quantities snort from ad, and have used the known quantities representing her weights of hull, of equipment and armament, and of engines, boilers, and coals at the time of her trial, and of armour and backing on batteries and belt, in order to determine the correbatteries and belt, in order to determine the corresponding quantities in the new design for a ship having the same form and proportions below water as the "Minotaur," but in other respects fulfilling the same conditions as the "Hercules" in the manner explained above. I have also taken the indicated horse power developed in, and the full speed realized by, the "Hercules" on her load draught trial in order to determine the proportion of indicated to nominal horse power in the engines which would drive the new ship at the same speed, thus ensuring that the new ship shall have engines of an identical drive the new ship at the same speed, thus ensuring that the new ship shall have engines of an identical character with those of the "Hercules." In determining the coal supply of the new ship, I have considered it proper to provide such a weight as would enable her to proceed under the half-boiler speed attained by the "Hercules," as far as the "Hercules" could steam at that speed. This is obviously just to the long ship as the half-power speed is the maximum which would be employed in all cruising services when under steam. vices when under steam.

As the result of careful calculations made in ac cordance with the above-stated conditions, I am enabled to give the following dimensions and parti-culars of the new ship; and, in order to compare them with the corresponding features in the "Her-cules" at the time of trial, have arranged the subioined table:-

	New ship.	"Hercules."
Length between perpen-}	385ft.	325ft.
Breadth extreme	57ft. 2in.	59 ,,
Tonnage B.O.M	5,936 tons	5,226 tons
Nominal horse power	925 H.P.	1,200 H.P.
Indicated	6,585 ,,	8,529 ,,
Weight of hull	4,574 tons	4,022 tons
,, armour and backing, in belt}	1,518 ,,	1,292 ,,
Weight of armour and ) backing, on batteries)	398 "	898 "
Weight of engines, boilers, and coals	1,460 ,,	1,826 ,,
Weight of equipment and }	1,138 "	1,138 "
Displacement	9,088 ,	8,676 ,,

From these figures it will be seen that the new ship would be 60ft. longer, and 1ft. 10in. narrower than the "Hercules," and that she could be driven at the the "Hercules," and that she could be driven at the some full speed by engines having a nominal power 275-horse power less than the engines of the "Hercules." Her tonnage, however, is 710 tons greater than that of the "Hercules," and her construction would consequently cost considerably more, while her engines would cost less, and her expenditure of fuel not be so great as that of the "Hercules." Hence, apart from the question of handiness, it becomes necessary, in contrasting the merits of these ships, to determine the difference of prime cost ships, to determine the difference of prime cost approximately. Taking £55 per ton of tonnage as the cost of the hull, which is a fair average for iron-clads, and taking £60 per nominal horse power as the cost of the machinery, which is also a fair average, we obtain the following results:—

Excess in the prime cost of the cost. £

Excess in the prime cost of the hull of the new ship over that of the "Hercules"

Decrease in the residue of the residue of the state of the state

becrease in the prime cost of the machinery of the new ship from that of "Hercules" H.P. =275×60 = 16,500

Excess in the prime cost of the hull and engines of the new ship over that of the "Her-£22,550

This will, I think, be admitted to be a considerable saying, and one which can scarcely fail to show the desirability of building ships of moderate proportions

desirability of building ships of moderate proportions, even if we have to increase the engine power in order to obtain the very high speed.

There may, however, still be a suspicion in the minds of some advocates of long ships, that the additional cost of maintenance for the more powerful engines of the "Hercules" would, in a comparatively short time, make up for the difference in the prime cost, although that difference is considerable. I shall attampt to show what the difference of cost of shall attempt to show what the difference of cost of maintenance may amount to, in order to clear up this point; but, before doing so, I must draw attention to the fact that the new ship, being more than 700 tons burden greater than the "Hercules," will require an addition of at least fifty men to her crew, intended.

and that the cost of their maintenance will be considerable. Taking £70 per annum as the average total cost per man per annum, this would involve an additional annual outlay on the large ship of £3,500. additional annual outlay on the large ship of £3,500. From calculations based upon the average consumption of coal in ships with the improved type of engine, it appears that the cost of fuel in the new ship, for a day's steaming (twenty-four hours) at half boiler power, would be less than that in the "Hercules" by a little over £15. Hence it follows that the saving of wages and provisions in the "Hercules" as a contraction of the power has a result of the contraction. cules," as compared with the new ship, would cover the difference in the cost of steaming at 12 knots for 229 days of 24 hours each in the year. I need 229 days of 24 hours each in the year. I need hardly say that our ironclad ships are not under steam for anything like that time in a year, and consequently the difference in cost of fuel for the two ships would be much more than counterbalanced by the smaller expenditure required on the crew of the "Hercules."

Even if this necessary difference in the numbers Even it this necessary difference in the numbers of the crew were waived, it will be obvious, from the facts just stated, that the interest, at a low rate, on the difference of prime cost, would quite make up for the additional cost of fuel in the "Hercules," supposing her to be in commission and on general service. This matter, in my opinion, is thus placed beyond question service. This me beyond question.

Having disposed of this objection, it is only fair that I should call attention to the facts that the "Hercules," being smaller, is sure to be less costly in repairs than the new ship would be; and that the fact that she is 60ft. shorter cannot fail to render her much handier. In several parts of this paper, I have had occasion to refer to this latter feature of short ironclads; and it may be thought that undue stress has been laid upon the point. A study of the reports of the admirals of the Channel squadron will, however, show that experienced seamen also hold the opinion that handiness is one of the most important features of a ship of war. I need not quote from those reports in proof of this statement, but may add that the length of the "Achilles," "Warrior," and other of our long ironelads has again and again been pronounced so great as to inter-fere with the manœuvring power, while the shorter ships—such as the "Bellerophon" and "Lord Warden"—have been warmly praised for their handiness. The "Hercules" has also been shown On a review of the facts brought before the Insti-

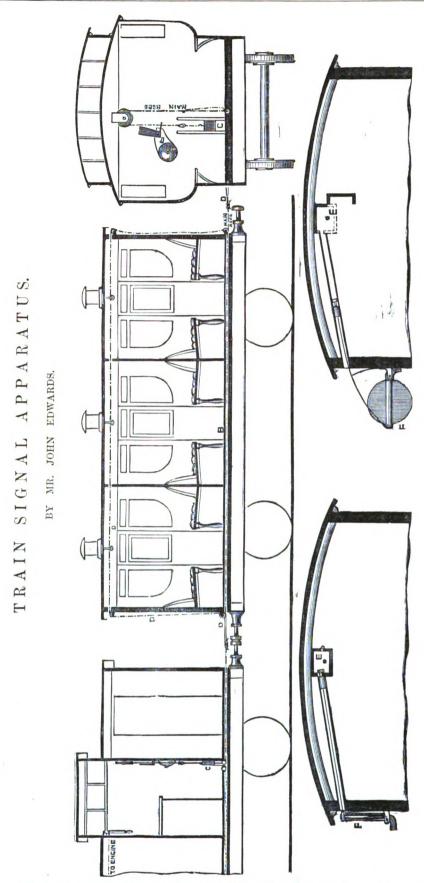

On a review of the facts brought before the Institution in this paper, it can, I think, be scarcely
doubted that the policy of building armoured ships
of moderate length and proportions is superior to
that of adopting greater length and fineness of form.
The change from the "Minotaur" to the "Bellerophon" was undoubtedly very great; but I submit
that experience has shown it to be a proper one, and
the construction and trials of other ships of nearly the same proportions have tended to confirm this view. In prime cost, handiness, and general efficiency, short ships have been shown to be better than long ships. In economy of engine power, long ships may be, and, in some cases, undoubtedly are, superior to short ships; but, since this economy is inconsiderable in proportion to the total saving, it may be fairly concluded that the shorter ironclads are, on the whole, greatly to be

preferred.

### TRIAL TRIP OF THE "HINDOSTAN."

YESTERDAY week, the "Hindostan," a fine clipper steamer for the Latinger steamer for the opium trade, was tried at the measured mile, and attained a speed of 121 knots, on a mean draught of water of 17ft., and the impression was that had the vessel been 15in. by the stern, a much greater speed would have been attained. The "Hindostan" was built for Messrs. Asscar and Co., of Calcutta, by Messrs. J. Wigham, Richardson, and Co., of Newcastle-upon-Tyne, and engined by Messrs. Thompson, Boyd, and Co. The cylinder of this vessel's engines has a diameter of 64in., with a 3ft stroke, and developed an indicated horse-power of 1,440. They are fitted with surface condensers, and all the best arrangements for economizing fuel. The circulation of the water in the condensers is effected by a centrifugal pump, made by Messrs. J. and H. Gwynne, of Hammersmith, which gave a most satisfactory result. The dimensions of this splendid steamer are:—Length, 300ft. 6in.; breadth, 35ft. 2in.; depth, 22ft. 6in. There were on board the representatives of the owners, who were in every way satisfied with the vessel's performance, and her yacht-like model called forth many compliments to Captain R. B. Durham, who has had the entire designing, planning, and superinten-dence of the vessel and her machinery. The saloon is fitted to accommodate forty first-class passengers, and, together with the sleeping borths, is most elegantly furnished and decorated; and every care appears to have been taken to adapt everything to the climate for which the vessel is

EDWARDS' SYSTEM OF TRAIN SIGNALS. A FEW days since, the system of train signals, invented by Mr. John Edwards, C.E., of No. 157, Richmond-road, Hackney, was tried at Brighton, in the presence of Colonel Yolland, the Brighton, in the presence of Colonel Yolland, the Government inspector. A train, consisting of an engine and tender, one front brake van, twelve carriages, and a brake van in the rear, was fitted with Mr. Edwards' signal apparatus, and made a run from Brighton to Shoreham and back, a total distance of about twelve miles. The system, which is called by the patentee the A B C system, is illustrated in the accompanying engravings. It consists of a cord carried through a ½in. tube B,

under the body of the carriage. This cord is coupled between the carriages by simple S hooks
To this main rope is attached a weight C in each guard's van, the one weight being heavier than the other, acting, to use a paradoxical term, as a fixed yet movable point. The heavy weight rests

a manner that the passenger is made to pull direct to the guard, who signals the driver, if necessary, by the ordinary means at his disposal. The passengers are not, therefore, in a position to signal direct to the driver, the guard's discretion being considered sufficient for the purpose of stopping where necessary or going on to the next station. As in other systems, the precise carriage from which the signal has been passed is indicated, the pull rope being passed through a mahogany case E, 2in. by 1½in., fixed to the under side of the carriage roof, the cover of which case being turned downwards acts as a detent holding up a disc fixed on the outer sides of the carriage. A passenger who may wish to communicate with the guard must open the case so as to get at the cord, and his doing so at once liberates the disc F, which then drops by its own weight into a horizontal position, was given. In the A B C system, if a train breaks in two parts, both guards are warned simultaneously by the tension of the cord, which acts as though pulled by a passenger, and, by raising the weights, the gong is struck by the arm which the small weight threw out of gear, the arm remaining rest-ing on the gong until readjusted by the guard. On the outward journey, six signals were passed from Mr. Edwards, all of which were duly received; but on the return journey twelve signals were passed, and, rather strangely, fourteen signals were received. It was noticed that the coupling-hooks prevented the rope being drawn within the tubes more than 18in. or 20in.; but if a greater length of indraw be necessary to give a signal, the system

would be perfectly useless.

Previously to the trial of Mr. Edwards' system of train signalling, that invented by Major Wethered had been tried in the same train. The latter system consists of a series of rods running on pulleys fixed below the floor of the carriage, and which are coupled to iron chains, the cord by which the passenger gives a signal being connected with the chains. The signal handle is fixed in a with the chains. The signal handle is fixed in a pigeon-hole between the compartments, and accessible to each by tearing away a paper, which covers the aperture on either side. When the passenger pulls the handle, a lever is released from its detent, the falling of which draws up the slack to the extent of 5ft. or thereabouts, and a bell or gong is sounded in the guard's van. On the signal being struck, discs and arms fall out, so as to indicate the carriage from whence the signal was passed. The trip was about twenty-two miles in passed. The trip was about twenty-two miles in length, and a number of signals were passed, which acted on the whistle of the engine on the outward acted on the whistie of the engine on the variation journey, and on the return journey were passed to the front guard's van, and from the guard direct to the driver by means of the usual connecting chain. We are informed that all the signals passed in a very satisfactory manner, except two. In the first of these instances the signal was passed from a third-class carriage, and failed to take effect a third-class carriage, and falled to take effect but from the same carriage eleven signals were subsequently given, and all were duly received. In the second instance, Mr. Craven, the locome-tive superintendent of the line, pulled the wire rope, which snapped like a piece of common twine. The rope in question had been tested to 360lb. breaking strain. Either Mr. Craven was extra strong at the moment, or the rope extra weak.

The comparative results of these trials are given in the following table, which shows the strains on the signal cords of both systems:-

Friction of cord through 12

ems:—
Wethered's Edwards'
101b. ..... 81b. 24,, ..... 14,, Wire rope. Fishing line

Friction of cord through 12 carriages 51b. ..... 3lb.
Friction through each carriage 5-12, ..... 3-12,
The Edwards' or A B C system, therefore, has the advantage of the Wethered system in the foregoing respect. It is also less expensive to apply, the cost being less than two-thirds lower than that of the Harrison system, and considerably less than that of the Wethered system. Mr. Edwards has now ascertained that the railway companies do not intend using detectors, in consequence of the extra expense. This, of course, further reduces the cost expense. This, of course, further reduces the cost of the A B C system to the merely nominal sum of 1s. 6d. per carriage, and Mr. Edwards assures us that he is prepared to supply any quantity of materials at that rate. From the position of the main rope, and the method of using it, the cost of maintenance is reduced to the smallest possible amount. Should experience prove the necessity of using detectors, they could be added to the A B C system without disarranging any of the

#### WELL FOUNDATIONS.

T a meeting of the Institution of Civil Engineers, A held March 2, 1869, Mr. C. H. Gregory, President, in the chair, the first paper read was on sinking wells for the foundations of the piers of the bridge over the river Jumna, Delhi Railway, by Mr. Imrie Bell, M. Inst. C.E.

After alluding to the native plans of sinking

wells, built of masoary or brickwork, by excavatwous, built of masoury or brickwork, by excavating the sand from the interior, at first by means of a spade called a "phaora," and after the first 5ft. by an implement called a "jham," reference was made to a modification in the use of the "jham," in constructing the railway bridge over the Jumna at Allahabad, where instead of sending down a diver to force the spade into the ground, a pole was employed to strike the butt end of the "jham" and so to drive it into the ground. This was, in the author's opinion, a decided improvement; but the process was still tedious and slow, especially where clay or hard strata were met with.

The author then proceeded to describe the mode of forming the foundations of the bridge over the river Jumna, near Sirsawa, on the Dolhi Railway. It appeared that the bed of the river at this point consisted of coarse and fine gravel and sand, interspersed with layers of blue clay 3ft. and 4ft. thick, and covered with silt; but during the rainy seasons large boulders, weighing 14lb, each and upwards, were brought down, and deposited by the scour of the river 30ft. below the level of the bed. The bridge comprised twenty-four openings, each 99ft. in the clear, and the superstructure was composed of two lines of lattice girders, resting on brick columns, or wells, each 12ft. 6in. external diameter, and 5ft. 10in. internal diameter, so that the wall of the well was 3ft. 4in. thick. In some instances, the sites of the piers were got clear of water by diverting the river at different points during the dry season, while in other cases islands were formed, by driving a half-circle of piles on the up-stream side, then lowering sand bags on the down-stream side, to the height of 4ft. or 5ft., and afterwards filling up with sand to 5ft. above low water. The curb on which the steining of the well rested was formed of wrought-iron plates and angle irons riveted together; and in cross section the curb was like an inverted right-angle triangle, of which the height was 4ft., and the base 3ft. 4in. When each curb was complete, it was moved into position, and the compartments were then filled in with concrete. The curb was next sunk by men working with the "phaora" and basket, till the upper edge was within 3in. of the level of the water, when a ring of brickwork was carried up for a height of 6ft. The excavation of the interior was again proceeded with, by means of the "jham and divers in the old native style; afterwards a further height of 10ft. of brickwork was added, but the material was now removed by a sand-pump (to be hereafter described) worked by a steam hoist of 4-horse power, as was the case after two additional lengths, each of 15ft., were built, when the well was carried down to its full depth. In operations of this nature, great care was necessary, especially at first, to insure the well, or cylinder descending vertically. For this purpose, the curb should invariably be sunk alone without any building. The first height of brickwork should not exceed 5ft. or 6ft., the next 10ft., and it was never advisable to build more than 15ft. at a time. Before commencing any additional height, the top course of the brickwork already built ought to be removed, to insure a thoroughly clean surface for the mortar.

The lime used at the works was made from marl, or, more properly, calcareous clay, which, while soft, was roughly moulded into bricks. These were stacked to dry for three or four days, and were afterwards burnt with wood in kilns for fifty or sixty hours. The flues were then closed with bricks and mud, and so allowed to remain for two or three days. On the kiln being opened, the lime bricks were unloaded almost in a whole state, were ground under stones, screened, and carried to the works pure and free from ash or dirt. The mortar was made from one part of ground lime and one part of clear, sharp sand. This mortar was used in all the well foundations of the bridge up to the level of low water; and as a proof of its quality it was stated that it was easier to break the work as a mass than to separate it at the joints or beds. Above the level of low water, the mortar was composed of white hill lime, and soorkhee, or crushed brick bats, in equal proportions, as it was found that the lime from the calcareous clay lost the greater part of its cohesion when used in work exposed to the vicissitudes of the atmospherewhether this arose from the frequent changes from drvness to humidity, or from heat or cold, was not

The well sinking for the foundations of the piers and the abutments of this bridge was completed in little more than two years, which, without deducting any time for building up the brickwork, or for that unavoidably lost by the rise in the river during rains, gave an average rate of 159ft. per month. The time occupied in the building of the steining of the wells, erecting taking down, and re-erecting scaffolding and staging for sand pump, weighting the wells, &c., was equal to that employed in sinking. This would give the rate of sinking as a sinking. This would give the rate of sinking as a little over 300ft, per month. If cast-iron cylinders had been used, the work could have been performed much more quickly, as the portions of the cylinders could have been put together more rapidly, and owing to the slight bearing surface exposed by the thickness of the iron, compared to the breadth of the brickwork in the walls of the well. The total weight of the foundations and of the iron girder superstructure on each well was 420 tons, and the area of the bottom of each well was 117ft., so that the weight was less than 4 tons per square foot.

The novelty in the sinking of the wells of this bridge was in the use of the sand pump. This was described to consist of a wrought-iron cylinder having a pump riveted to it at the top, in which was a piston fitting loosely, and pierced with small holes to allow of the escape of water. The piston rod terminated in an eye at the upper end, to which a chain could be attached. The bottom of the cylinder was movable, and in the centre there was an upright suction pipe, projecting outwards for a distance equal to its own diameter, and inwards nearly to the top of the cylinder. When the pump was lowered to the bottom of the well, the chain attached to the piston rod was worked up and down like a ringing engine. In this way, water was first drawn through the upright pipe, followed by sand or other material, which fell over the pipe into the cylinder. This operation was continued until the cylinder was quite full, which was known by the piston working stiffly, when the machine was raised to the surface; the bottom of the cylinder was then detached, with the column of sand resting on it, and another cylinder bottom which had been cleared of its sand was substituted. The number of men employed at each well was fourteen; nine working the chain, two clearing away the stuff brought up by the pump, one in charge of a steam hoist, one breaking firewood, and an overseer. The average of sinking, including contingencies, was about off. in eight hours. This rate was extraordinary when compared with the old system of the "jham" and diver, and would, it was believed, materially reduce the expense of bridge work in India.

In conclusion, reference was made to other methods adopted in this country for sinking cylinders; particularly to a machine on the dredger principle, which had been used in the construc-tion of the new bridge over the Clyde, at Glasgow, and to the excavator which had been employed in sinking the cast-iron cylinders for the foundations of the piers of a railway bridge over the same river, and which formed the subject of a separate paper. On considering the different plans, the author stated that he thought most favourably of the sand pump of Mr. Howard Kennard (Assoc. Inst. C.E.), as from its simplicity it was peculiarly adapted for India and for localities where skilled labour could not readily be procured. Some improvements which had been effected in the details were then described, particularly in the substitution of the movable bottom for the side doors as originally made, and in adapting the pump for piercing clay at the Sutlej Bridge Works.

The second paper read was a description of apparatus for excavating the interior of, and for sinking, iron cylinders, by Mr. John Milroy, Assoc. Inst. C.E. It was believed that, for the purpose of sinking cylinders, the great desideratum hitherto had been some method of excavating the earth from the interior without at the same time having to take out the water, and to keep it out during the operations. This object seemed to the author to have been attained by a machine of his invention, which was used in the construction of the bridge over the river Clyde (City) Union Railway, to which Mr. Fowler (past president Inst. C.E.) and Mr. Blair (M. Inst. C.E.) were the engineers. This machine will be found fully described and illustrated in the MECHANICS' MAGA-ZINE for May 22, 1868.

of a wheel, T-irons from a small cast-iron ring in the centre. To the bottom of the outside rim were hinged eight heavy iron spades, which, when drawn in, fitted closely, with their points pressing against the inner ring. The hinges of the spades were so constructed as to prevent them from turning back beyond the perpendicular. The whole apparatus was very strongly made, and it formed when closed a nearly water-tight tray. When the machine was descending, the spades were allowed to hang vertically, and they were forced into the ground by the aid of two chains fastened to the top of upright arms on opposite sides of the excavator, then passed down the cylinder, under a pulley, up between two leaders, and over another pulley, the end of each chain being wound round the large axle of a capstan or drum on the landing These chains were calculated when tightened to keep the machine down whilst the spades were being drawn in through the ground and up to the frame. This was effected by a second set of chains, all of equal length, and each fastened at one end to the inside of a spade and at the other to the end of a main chain, by which the machine was raised to the surface with the earth it con tained by means of a steam hoist. In order to enable an opinion to be formed of the capabilities of the excavator, it was mentioned that the progress of the excavation, and the corresponding subsidence of the cylinder, reached from about 12ft. to 20ft. per day of ten hours, inclusive of the time employed in adding fresh lengths of cylinder, putting on weights, &c. When there had been little interruption for any of these purposes, it had amounted to 25ft. in the ten hours, and then the average quantity of sand brought up at each lift was 21 cubic feet, and the total quantity during was found by measurement to be 70 cubic yards. Twelve men in all were employed, viz., one engineer, one stoker, six men working the drums, three attending to the loading and discharging of the excavator, and one man wheeling away the materials.

In conclusion, the following advantages were claimed for this apparatus:—First, that it was per-fectly independent of water, which was allowed to remain in the pit or cylinder until the excavation was completed; secondly, that it could be used, and was equally effective, at any depth, without sensible difference in the cost of working; thirdly, that its rate both of sinking and of excavating was higher than had yet been attained by any other method; and lastly, that it was not liable to get out of order, whilst its action was always in the same perpendicular line, and the expense attending its working was comparatively trifling, as skilled workmen were not required.

MILITARY ENGINEERING OPERATIONS.

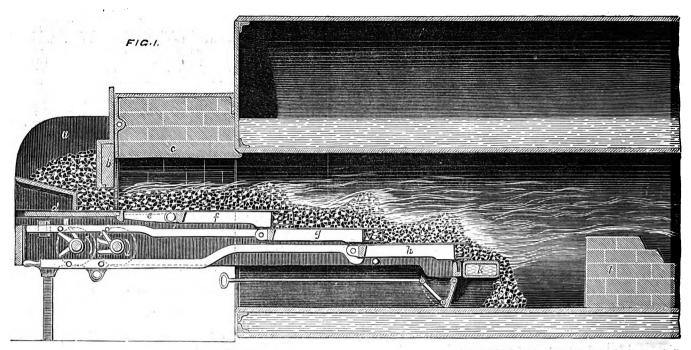

SOME interesting sapping and mining operations were carried on at Charles were carried on at Chatham yesterday week by the Royal Engineers, under the superinten-dence of Colonel W. O. Lennox, C.B., V.C., prin-cipal instructor in field fortifications at the Royal Engineer establishment, Brompton, Chatham. The object of the operations was to test the relative explosive powers of gunpowder and gun cotton when used in the destruction of permanent fortifications. In order to carry out the trials, several mines were sunk at that part of the fortifications known as St. Mary's hornwork, and were similarly placed behind the centres of counterforts of the escarp wall, between St. Mary's barrier and the batardeau, the charges being placed 11ft. below the top of the wall. Each charge of powder was of 2731b., while the gun cotton charges were each of 941b., or exactly one-third of the weight of gunpowder, gun cotton, it was asserted, having three times the explosive force of powder. The part of the fortifications operated upon were completely destroyed, although the results, so far as the use of gun cotton was concerned, were not so satisfac-factory as had been anticipated. Some further operations were also directed against the Townsend redoubt, behind the counterforts, 6ft. below the top of the escarp, and 2ft. above the bottom of the ditch, the charges used being gunpowder. The siege operations, which were carried out in the presence of Major-General F. Murray, Colonel T. L. J. Gallwey, director of the Royal Engineer establishment, and other officers, were considered very satisfactory.

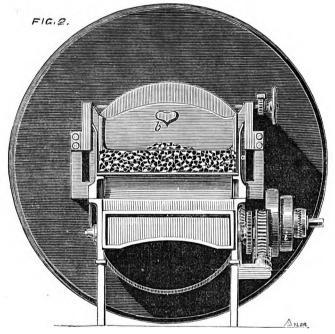

The excavating apparatus, commonly called the "excavator," was thus described:—It consisted of a horizontal frame of iron, with an outside rim opening of the Museum, free daily (May 12, 1858), 9in. in height, to which radiated, like the spokes 1,549,899.

### NEW SMOKE-CONSUMING FURNACE.

BY MR. T. WRIGLEY.

### WRIGLEY'S SMOKE-CONSUMING FURNACE.

THE annexed engraving shows a very good arrangement of furnace for the consumption of smcke, which is the patented invention of Mr. Thomas Wrigley, manager to Messrs. Fielden Brothers, of the Robinwood Mill, Todmorden. The engraving represents in fig. 1 a longitudinal section, and fig. 2 an end view of the furnace, as applied to a cylindrical boiler with one flue; it is, however, applicable to boilers of every description, and to other purposes. The furnace consists of a hopper a; the depth of feed is regulated by the door b, placed between the hopper a and the firebrick arch c. Under the hopper a is the dead plate d, connected to the grates e and f, the inner end of which overlaps the grate g, which, in like manner, overlaps the grate h. These grates are moved slowly to and fro by a strap passing round the driving pulleys i and the mechanism shown, or in any other convenient manner. Beyond the grate h is the water pocket k, the object of which is to protect the bearers of grates which would otherwise soon be burnt. The bridge l is placed a certain distance from the water pocket k, under which is a door to close the space under the grates. This door is opened occasionally to draw out the clinkers and cinders which accumulate in the

bottom of the flue between the water pocket k and the bridge l.

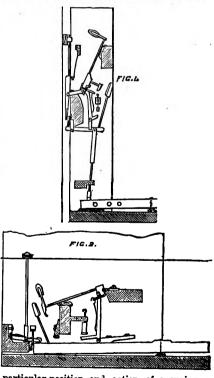

the bridge I.

The speed at which the grates move is varied to suit the coal, and the steam to be generated. But in all cases, as the coal is gradually brought forward, it is evident that the inflammable gases evolved by the fresh coal must pass over the entire surface of incandescent coal, and, consequently, be eignited before they leave the flue, thereby consuming the fuel in the most advantageous manner and entirely preventing smoke. Furnaces of this description are at work at the Robinwood Mill, where they are giving every satisfaction. They are stated to generate more steam than any furnace at present known. The labour of firing is greatly reduced, as the fireman has little else to do but to keep the hopper well supplied with coal, and the smoke is entirely consumed.

# BRINSMEAD'S PIANOFORTE REPEATER ACTION.

ROR long past, pianoforte manufacturers have sought to attain for their instruments a perfect check action, which should not affect the repetition. This they have not perfectly succeeded in doing, until the present time. There are actions

in use which profess to do it, but which practically do not achieve the object, inasmuch as their complicated nature renders them liable to derangement; besides which they do not respond to such a nicety as is required by professional players. We however, must say that the difficulty has been fairly overcome, and every requirement met in an action invented by Mr. John Brinsmead, the pianoforte manufacturer, of 18, Wigmore-street, Cavendish-square. This patent perfect check repeater action is illustrated in the annexed cuts, fig. 1 of which shows the action as applied to an upright piano, whilst in fig. 2 its application to a grand piano is seen. The substance of this invention consists in

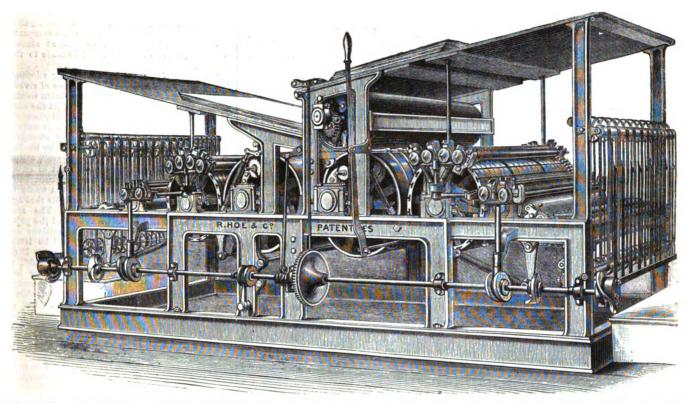

a particular position and action of a spring and loop, and informing the hopper or sticker with an incline at the top, which presses on the front of the notch after escapement has taken place. Mr. Brinsmead connects a spring to the lower part of the hopper, carries it up and forms it at the top into a hock. From the hook he carries a loop through a slot in the hopper, and connects the loop to the butt under the notch. A glance at our engraving will show the simplicity of this action, whilst its efficiency is placed beyond all doubt by

### TWO-FEEDER PERFECTING PRINTING MACHINE.

BY MESSRS. R. HOE AND CO.

an inspection of the principle as applied in practice to Mr. Brinsmead's instruments. A recent visit to the inventor's establishment assured us of this, a touch of the instrument making the point very clear. We do not, of course, refer to the matter from a performer's point of view, although we know something of that, and we know also that the arrangement is highly spoken of by the first professional players of the day. We do, however, speak of it as a mechanical arrangement, and as such pronounce it to be the most perfect we have seen, producing the most delicate repeats. To sum up, the advantages this action offers are—a perfect check without affecting the repetition, which is most prompt, acting with the least perceptible movement of the key. The touch is very sure, light, and elastic, giving the player every facility for producing forte and piano effects. The equally balanced arrangements, the absence of friction and of complication, ensure its durability, whilst the perfectness of the touch cannot fail to render it popular with players.

### HOE'S TWO-FEEDER PERFECTING PRINT-ING MACHINE.

In the annexed engraving we illustrate a new patent two-feeder perfecting printing machine for stereo plates of any size up to 60in. by 33in., and which was invented and is manufactured by Messrs. R. Hoe and Co., of No. 62, Dorset-street, Salisbury-square, London, and of New York. This excellent machine is constructed to meet the want of newspaper proprietors whose circulation is not so large as many of the London daily papers. It occupies a floor space of 18ft. by 7ft., the height being 7ft. In working, the sheets are fed in singly by two boys upon the same cylinder, and then conveyed by grippers to the impression cylinder, and thence to the forme cylinder, where the stereo plates are fastened on by means of small and convenient clips. The plates are inked while the cylinder is revolving under the inking rollers, which receive their supply of colour from a simple distributing apparatus. The sheet is then printed on one side and conveyed by grippers to the second impression cylinder, where the formes are inked in a similar manner, and perfected; they are then conveyed to the tapes, and thence to the self-acting sheet flyers, and by them laid in precision at the rate of 4,000 per hour.

The machine is specially deserving of notice on

The machine is specially deserving of notice on account of its rapid speed, compactness, and quietness in motion. It is simple in construction, not liable to get eut of order, and can be worked by

any ordinary machine minder. The first machine was made for Mr. Edward Lloyd, of "Lloyd's Weekly Newspaper," who has since ordered a second machine.

# ON ZINC SHEATHING FOR IRON SHIPS.\* BY MR. BENJAMIN BELL.

THE question of protecting the bottom of an iron ship from corrosion and fouling has always been one of the greatest interest, but, during the last year or two, my attention has been, by special circumstances, more particularly called to this subject. We have been building, at the Thames Iron Works, two corvettes of 2,321 tons each—the "Volage" and "Active," just launched for our own Admiralty—in which the object of keeping a clean bottom is sought to be attained by constructing first a complete iron hull, sheathing it with two thicknesses of wood, the first fastened with iron bolts screwed through the hull plates; the second fastened with copper screws into the first, then screwing the copper, as in a wooden ship. Two ironclad frigates of nearly 4,000 tons each have been ordered, and are building on the same plan; and a larger corvette, the "Inconstant," of 4,000 tons, has been built at Pembroke on a plan differing somewhat in detail but of the same character. In the summer of 1867, the Thames Iron Works Company, in common with other leading ship of war, and, amongst other points, were especially asked to propose any plan which they could recommend either for coppering or zincing them.

In the course of building the "Volage" and "Active," I have been very strongly impressed by

In the course of building the "Volage" and "Active," I have been very strongly impressed by the great difficulties and enormous cost of producing a perfect work of which the essential condition was the absolute insulation of the iron hull from the copper, and of maintaining that insulation throughout under all contingencies, and against all accidents. I can well appreciate the anxiety of the Chief Constructor, the designer of the ships, and his officers, that their object should, at least in the beginning of the ship's life, be obtained; and the anxiety, perhaps not less, which must arise from the consideration of the many contingencies that may hereafter defeat it, and bring together under water such deadly enemies as copper and iron. If I may venture to express an opinion, it would be that, in constructing, first, a complete iron vessel not only with iron frames, but entirely iron-plated,

· Read before the Institution of Naval Architects.

and obtaining thereby the rigidity and freedom from working of an iron hull, the best, and perhaps the only, security is obtained; but all the money and pains which have been expended are liable, over a large extent of surface, and by a variety of causes, to be at once rendered useless. The fact being well known that zinc bears to iron just the opposite relation of copper, and that galvanic action established between the two metals results in perfect protection to the iron and a corresponding exfoliation of the zinc, it would certainly seem that in its application to an iron ship, an escape from all these difficulties might be hoped.

I do not propose to go into the question of compositions. The foregoing facts are enough to show that in the opinion of the English Admiralty—no doubt the best judges of the matter, and the most deeply interested therein—no existing compositions really meet the difficulty of the fouling of an iron bottom, nor is there much prospect of success in this direction, but that we must resort to a metallic sheathing. It is, I think, accepted that no smoothness of surface, no poisonous or electrical character of the composition, will keep off the barnacle, and that the only means of accomplishing this are the corrosion and exfoliation of the surface, which, in parting with a portion of itself, parts company also with its parasites. If zinc, when acted upon galvanically, will exfoliate as the copper does on a wooden ship, and if this exfoliation can be controlled and regulated to the proper point, it would then follow that we only want a feasible method of securing it under proper conditions for this galvanic action to the iron ship to supply this desideratum. I assume that the first of these points has been settled by decisive experiments. Those made at Sheerness and Portsmouth, at the instance of Mr. Daft, and all the experiments made by the French Government, which are not a few, give decisively this result, that the zinc corrodes and kept clean, at the same time protecting the iron. As to the second, I have learnt lately that for some years past, in a large line of steamers sailing out of Liverpool, zinc has been used to protect the boilers and iron tubes, where surface condensation is practised, from being destroyed by the corrosive action of the water, which has passed through the copper condensing tubes. The plan adopted has been to hang up in each stack of tubes a large piece of zinc suspended in the water; this is rapidly destroyed to such an extent that fin. of zinc disappears in less than a month, while the boiler itself and the iron tubes are completely protected.

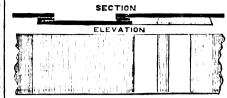

On wooden ships, zinc, as a sheathing, has l

On wooden ships, zinc, as a sheathing, has long been used as a cheap substitute for copper for the

sake of protection against water, and for comparative cleanliness. Here there is little or no contact with iron, a very small amount of galvanic action, and consequently, a small exfoliation of the zinc which lasts for years almost uninjured. not, therefore, keep the bottom as clean and bright as copper, but it approximates thereto, pays for its use, and is better even thus than nothing. It appears to be the irresistible conclusion, from facts like these, that we have the exfoliation of the zinc completely under control from the minimum on the wooden ship, with little iron contact, to the maximum in the water and steam of an iron boiler: and, this admitted, that we have only to get a combination which will make the zinc exfoliate at the same rate as the copper on a wooden ship to obtain the same result of a clean bottom. We have then to attach the zinc to the iron bottom, and to do so under suitable conditions for regulating the galvanic action; and it is with this proposition that I have attempted to deal. Two methods have been proposed and experimented upon, both of which go upon the supposition (in which I entirely conthat, in some form or other, wood must be used as an intermediary between the iron and the zinc; no plan of attaching it by cement or adhesive compounds has given the smallest hope of success. One plan, that of Mr. Lungley, has been to coat the iron ship completely with wood, secured by channel iron riveted to the ship's side, and then fastening the zinc as the sheets of copper are fastened to an ordinary ship. The other, that of Mr. Daft, has been to leave a small opening between all the longitudinal and vertical edges of the plates. filling in this with a tongue of compressed wood, and fitting sheets of zinc of such size that their edges exactly coincide with these tongues, and fastening them thereto with nails. In the former case, as the conditions appear almost identical with those of a wooden ship, and the galvanic action a minimum, much difference of result could hardly be anticipated, and, so far as I am informed, such was the result of an experiment which has been To the latter plan, the objections have been urged that a fastening only by the edges of the sheets of zinc to so small a tongue of wood could hardly be depended upon, and if supplemented by fastenings into the central parts of iron plate, great cost would be involved, while it was not desirable, in view of structural strength, to separate the butt edges of the plates of an iron ship. I have no disposition to exaggerate or even to enforce these objections, but they have hitherto prevailed to prevent any ship from being built on this plan, and it is certainly exposed to this difficulty, that to try it fairly requires a very large ship to be built. The tongues of wood can only be as thick as the plates between which they are placed, and, in small ships with thin plates, this would give no sufficient foundation.

The plan which I propose may be regarded as a mezzo-termine between these extremes, with the advantage of being available for every size of ship, and having great elasticity in its application to produce whatever amount of galvanic action may be found on further experience desirable. It has already been proposed, as a method possible of application to our largest ironclads, to fill up the hollow in the side of the ship, between the inside and outside strakes, with wood, and to fix the sheets of zinc over, and in contact with, the iron surface, fastening them into the wood. This would give a flush surface to the ship, a proportion of shout one-half of contact with iron and with wood which would probably give a very good result as to cleanliness. I have myself recommended strongly in certain quarters the trial of this plan; it is, in fact, out of this that my present proposition has arisen, but the objection has provailed, and I have felt compelled to acquiesce in it, that a thin filling of wood \(\frac{1}{2}\)in. to \(\frac{3}{4}\)in., which is about what our largest ships will allow, would be of doubtful sufficiency to hold on the zinc. It is precisely with this insufficiency that I have proposed to deal, and I submit two alternative methods of doing so. What is done is simply to increase this hollow to such an extent as to give a thickness of wood strong enough to hold securely the fastenings of the zinc. One of these methods is adhering to the ordinary plan of building the ship with longitudinal lap joints, giving an inside and outside plate to interpose between these laps before riveting them together, a band of iron, the breadth of the laps of the necessary thickness increasing thereby the relief of the outside plate; single riveted, and no sign of weakness has the other, which is in principle the same, is appeared from this cause. So far as the structure adopting a method sometimes used to have all the plates home to the frames, with flush edges, and laps is equally applicable to double or single rivetto rivet these together by an outside longitudinal ing, but this has an important bearing on the

butt strap, increased beyond the ordinary proportionate thickness, due to the strength necessary for the connection of the plates to that required for giving the relief wanted for a wood filling sufficiently strong, as in the former plan. In the drawing, I have taken §in. as an average thick-

ness of a ship's plating, and have inserted between the laps a gin. strap, giving thereby a hollow of 14in., which, filled in with wood, should, I think, be strong enough to hold the zinc. In the other plan, the same result is produced by putting on a butt strap or outside plate 14in. thick; this has been taken on the assumption that wood 14in. thick is the proper strength to hold the nails securing the zinc, but obviously the plan permits of this thickness being either diminished or in-

creased as experience may prove desirable. With respect to the bearing of these plans on the structural strength of the ships, I would observe that they are both simple, involving nothing in principle novel or difficult, or materially differ-ing from the ordinary forms of iron shipbuilding. To the latter form, that of the outside butt strap, no structural objection has occurred to me. There are, indeed, advantages in having all the plates home to the frames, and all the edges supporting each other. To the first form, that of the strip between the laps, it did at first occur to me that the riveting of three thicknesses instead of two was, per se, objectionable, and that the separation of the two lapped plates might, by increasing the leverage where strains come on the ship, increase the power of shearing or bending the rivets. to the first point, however, I have considered that in ships built with plated keels we are continually riveting together five thicknesses of iron, i.e., the keelson, the two outside keel plates, and the two garboard strakes, and find no practical difficulty nor objection to doing so. As to the second, I have made some experiments which have led to the conclusion that there is no real disadvantage, but rather the reverse. The introduction of the strip rather the reverse. The introduction of the strip between the laps adds just 50 per cent., or what is due to the increased section of iron to the power of the lap to resist all longitudinal strains. transverse strains, there is no difference, because the real point of weakness is at the rivet holes where the sectional area is most reduced, and where, from the necessity of caulking, the space between the rivet holes is fixed at a maximum that cannot be exceeded. There is no question of shearing or breaking the rivets themselves because, as riveting is now done, the power to resist this is always much greater than that of the plate itself, weakened by the rivet holes. Here is a point of minimum strength which cannot be helped. Undoubtedly, if it were a question only of two plates riveted at the laps, the two plates would always break across the rivet holes, and those with the strip would break sooner that those without, simply because they would be more distorted, the pull not being in a direct line. But then this is not the case in a ship, because the frames and stringers, and the whole combination of the ship, tend to keep the plates in the direct line. As against buckling, the plan will give greater power of resistance: the double lap will give that; the thickened liner will, so far as it goes, give the same result, and the wood filling will also give some addition of stiffness to the side.

Considering, in fact, that for all longitudinal strains the lap is made absolutely stronger than an equal portion of the solid plate, I express the opinion, as worthy of consideration, that on this plan there is no necessity for double riveting. It adds nothing at all to longitudinal strength, and little, if anything, to transverse strength, and the plan proposed adds to the strength of the ship in the direction where it is really needed, and, if it does at all reduce it, it does so where it is least needed. I am not aware of any instance in which a ship has been lost by a failure in a transverse direction of the riveting, whether double or single. The largest ship affoat, the "Great Eastern,"

question of cost. I have gone into this with reference to a ship like the "Volage," and have found that, supposing no change to be made otherwise in the ship, she could be sheathed and zinced at a cost of less than £1 per ton over the ordinary plan, and an addition of half an inch to her draught. But, if I am right in supposing that double riveting can be saved, then the compara-tive increase of cost would be reduced almost to nothing, and no increase would be made to the draught.

In the case of the outside strip being adopted. there would necessarily be a double row of rivets, and some addition to cost, but this addition would, I think, be very trifling, considering that the outside strips would contribute to longitudinal strength, and the liner is entirely saved, which is only a filling, and does little duty in giving strength, while the lateral strength is increased by having all the edges of the plates supporting each other. I think on this plan a ship can be built of equal strength, with no addition to the total weight of iron; the wood need only be fillings, the waste of a yard, put on diagonally with a few bolts through the side here and there to fix it. The zinc sheathing costs little, less than a third the price of copper, while all expensive compositions are saved. The first cost, therefore, will be little, and would soon be well repaid, doing even little better than size or model at the costs. better than zinc on wood at present : it would, at least, keep clean longer than paint, require less frequent docking, and reduce the time and cost of At present, the cost of docking. that operation. cleaning, and painting an iron ship is 2s. a ton, or £200 for a ship of 2,000 tons, and it requires four or five days in dock. While the zine lasts—and I have an instance of its lasting seven years on a wooden ship, without being removed even to caulk the bottom--no painting is required; the bottom could be cleaned as the water leaves the ship in dock, and one tide would suffice for the operation, and one-third of the expense.

To one feature in these plans I attach very great importance, i.e., their elasticity and the power of varying their application, as experience may show to be desirable. We can give any thickness we please to the wood for holding the nails simply by to be desirable. increasing or diminishing the strip. We can do this on a ship of any size, and what is, perhaps, the most important of all, we can regulate at pleasure the proportion of contact between zine and iron. It is simply a question of the breadth of the plates, and in that part of the ship coated ith wood the galvanic action can be encouraged, if necessary, by driving the nails quite through and home to the iron. I am informed that this has been discovered and acted upon of late in wooden ships sheathed with zinc. They are now increasing the number of iron nails fastening it. and providing that all iron bolts in the ship touch the zine instead of being kept apart from it, and they have found that just in proportion as th y do this they get a cleaner bottom. No facts, which in studying this question I have learnt, have been so satisfactory and so conclusive as those which bear upon this point. They go completely to They go completely to establish the proposition that the zinc protects the iron, and that its cleanliness is simply and directly proportioned to the contact of the metals and the galvanic action.

In submitting this proposal to the First Lord of the Admiralty and the Chief Constructor of the Navy, I have learnt from Mr. Reed that the plan adopted by him in building the "Inconstant." to which I have referred as differing from the "Volage," is substantially the same, although for a different object, as that of the outside strip. her case, the plates are all flush longitudinally with a thick outside butt strap, the hollows between being filled in with wood. This strip was introduced to afford a means of fastening the thickness of wood, which is secured by screw bolts tapped into this strap, so that no holes are made through the side of the ship. To this the second wood sheathing is fastened, as in the "Volage." It seems to me very likely that I am here to-day simply because Mr. Reed was thinking of how to get the copper on to his ship, while I have been thinking of how to get the sing there. thinking of how to get the zine there. I have been able to say (and this is the proposition now before the Admiralty) you can try the experiment I propose without doing anything that you have not already done up to a certain point, and with the power, if the experiment does not succeed, of going beyond that point, and doing all that you have already done in the "Inconstant." You have only to build the "Inconstant" up to the point of the outside strip, and wood filling in between, with no other difference than that of putting

the edges of your strip at such an angle to the side as will hold on the wood, and stopping there to apply the zinc sheathing. If this succeeds, you save a great expense; if it fails, you can take off the zinc and go on and complete your ship with the wood and copper, like the "Inconstant."

It would be difficult to imagine more favourable conditions for trying an experiment, on which results of such immense importance hang. I need not here insist on the advantages which will be gained if this plan of zincing succeeds; if it does, it will follow that the iron ship can go on any distant station for long service; that the great cost of repairs of wooden ships, as compared with which iron ships cost almost nothing, will be saved. It signifies that as it is certain the iron will be absolutely protected against injury from without, you have an imperishable ship. It signifies that a clean bottom means a higher speed maintained, or an economy of coal, and a power of steaming a greater distance with the same quantity, a reduction of docking and of its cost. Supposing even that the zinc should not be quite equal to the copper, there are still the advantages of a flush surface, which will add to speed, and of facility for hogging when at sea, the preservation of the ship, and a better bottom than any merely painted one.

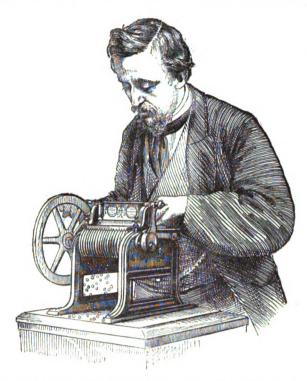

better bottom than any merely painted one.

Perhaps I can give no better measure of the importance of this question than is founded on what has been done by our Admiralty in the five ships to which I have referred. The addition to the cost of these ships, caused by the wood sheathing and copper, is not less than £6 or £7 per ton, as compared with what they would have been in iron ships; this means that the Admiralty have thought it wise to spend £100,000 or £120,000 for the sake of the advantage of such a clean bottom as copper gives. In spite of all the risks which it involves, beyond question, the advantage is worth all and more than the cost while it lasts; and it is sought to be effected by methods on which every skill and care has been expended in order to make them successful. But I found on this an argument which I trust will prevail for making an experiment which involves no risk, can result in no loss, and affords, at least, a fair promise of success. After what has been, it would seem to be impossible to go back to a mere iron ship, with paint or composition on her bottom: you must have a metallic sheathing. If that must be copper, then, even if it be true, as said by a leading scientific journal, the other day, of the wood and copper plan, that if that be the best plan, then bad is the best; we must do the best, however bad. But I say, build the ship so that you can try first the zinc. If that succeed, you have made a great economy; if it fails, then you have lost little, and can go on and fix the copper. The question has, I think, gone beyond the stage of mere experiment on parts of a ship; it should be fairly tried on a ship at sea. Doubtless there is much to be learnt which can only be learnt in that way; much may be necessary to settle completely the problem. I have strong faith that this is the true direction, and shall be more than content if I have contributed even a step to its final solution.

### BUSHBY'S PILL MACHINE.

THE accompanying engraving, which is of a somewhat more artistic style than we usually indulge in, serves a double purpose. It illustrates an ingenious pill-making machine, and at the same time presents an example of the graphotype process of drawing. The pill machine is the invention of Mr. Bushby, and is now rapidly being introduced here, and in America and France, where it is patented by Messrs. J. Bailey and Co., of the Albion Works, Salford, Lancashire, the well-known makers of patent mechanical novelties. Many attempts have been made to make a machine for this purpose, but without complete success. The inventor in the present case being a practical chemist, has so perfected the invention that 1,000 pills a minute are now made with ease. The following description may enable an idea to be formed of its principle:—The "pill mass" is first passed between two plain rollers to form it into a sheet of the thickness required for the size of pill to be made. The sheet then passes to the table of the pill machine, where it is caught by a self-acting feeding apparatus, bringing a portion under the edge of a knife, which cuts off a strip or bar, the strip falling or being carried by the knife between semicircular grooves, which, revolving rapidly, cut and form the strip into pills. The great economy of time will be apparent.

### BUSHBY'S PILL MACHINE.

sheet being intermittently advanced as each strip is cut off and formed into pills, another instantly follows, the shower of pills being continuous as long as the necessary sheet is supplied. The pills formed are spherically rounded, and by care in forming the mass into sheets of the required width, which is provided for on the plain rollers, a great quantity may be made without the waste attending the old process by hand. The machine is not liable to get out of order, the workmansnip being good and the mechanism simple—its great merit.

Pills are cheap enough now, in all conscience; for a shilling and three halfpeace we may enjoy weeks of internal disquiet at the hands of Cockle, Parr, Holloway, Morrison, and others. But we shall now have them cheaper than ever—or, at any rate, we ought so to have them by this labour-saving machine. But there is an evil in having pills too cheap as well as too dear; they may lead to over indulgence by those who have a morbid inclination in that direction. We are hereforcibly reminded of an anecdote told of the late Richard Roberts, the great inventor, who had a housekeeper whose ruling passion was a craving for pills. The worthy dame always had some imaginary ailment, and the most curious part of it was that she thought any pill of any kind good for her. Mr. Roberts suffered much from drinking water impregnated with lead, and had pills specially prepared to meet the case, and which he took at regular intervals. Somehow or other, the pills continually disappeared, and having an idea who abstracted them, Mr. Roberts devised a means of curing the pilferer. Being at his birthplace, Llanymynech, in North Wales, he gathered from off the Welsh hills a few of those small black rotundities to be found wherever sheep and goats abound. These were duly ensconced in pill boxes, and when he returned to his house in Bloomsbury-terrace, Lower Broughton, Manchester, Mr. Roberts placed them where he usually kept his pills. By degrees, the new pills gradually vanished; so the servants were called together, and told in a solemn manner of the importance of the pills to Mr. Roberts, on account of his complaint. Mr. Roberts also told them that he knew who had taken the pills, and that if the offender would confess and promise not to repeat the offence, he would overlook the matter and forgive the theft; otherwise, dismissal would follow. The servants went out in silence, but the housekeeper shortly afterwards returned, and, conscience smitten, begged forgiveness, at the same time stating her ailments and her reasons for taking the p

Turning to the second feature of our engraving —the illustration of the graphotype process—we

may observe that a full description of the system appeared in the MECHANICS' MAGAZINE for December 15, 1865. But as some time has elapsed since then, it may not be out of place here to state briefly the details of this invention, which is briefly the details of this invention, which is intended to take the place of wood engraving. The graphotype is the invention of Mr. De Witt Clinton Hitchcock, an American artist. The process is a very simple one. An artificial tablet of smooth chalk is obtained by reducing the finest French chalk to powder, and mixing it with water to the consistence of cream, separating the parts that precipitate, and repeating the operation several times to ensure an impalpable powder, capable of forming by compression a smooth, uniform sub-stance. This is spread evenly upon a smooth, level plate of zinc, over which a flat plate of steel, with a finely-polished surface, is laid above the chalk, which rests between the two metal plates. The whole is next submitted to the action of a hydraulic press, and put under a pressure of about 150 tons, which consolidates the chalk into a hard cake, with a surface like polished ivory. a wash of strong size is placed to guard against the possibility of the ink being used too thin, and so thickening and blurring the lines by spreading laterally. On this the artist makes his drawing, with the same care and lightness of touch, and in just the same way as line drawings are made on lithographic stones, with a brush specially pre-pared, and with a paint-like ink, principally com-posed of glue and lamp-black, with a little gly-cerine. When the drawing is made, it can be engraved in a few minutes, by being subjected to the action of a machine, which presses and whirls a brush with great rapidity on the surface, and by working downwards at right angles to the plate, working downwards at right angles to the plate, soon removes all the chalk not protected from its action by the artist's lines. The drawing is then in relief, and after being acted upon by a solution of silicate of potash, which gives it a stone-like hardness, is placed in the hands of the electrotypist, who produces an electrotype of it for the printer, just as he does from an ordinary wood engraving. We had almost omitted to mention that the illustration serves wet another and third that the illustration serves yet another and third purpose. The engraving is made from a photograph of Mr. W. H. Bailey, the energetic proprietor, of the above firm of J. Bailey and Co., and the inventor of many useful things, well known in the manufacturing districts. His patent improvements in pyrometers we hope shortly to illustrate and describe.

AT the ordinary meeting of the Society of Engineers, held on Monday the 19th inst., Mr. F.W. Bryant, President, in the chair, a discussion took place on Mr. F.W. Hartley's paper on "The Methods Employed in the Determination of the Commercial Value and Purity of Coal Gas."

### ROYAL HORTICULTURAL SOCIETY

THE second spring flower show of the Horticultural Society took place on Saturday last and notwithstanding the unpropitious weather which prevailed, the attendance was very large. The flower show was remarkable for the display of auriculas, cinerarias, and calceolarias. The miscellaneous plants were also very good and numerous. The principal prizes were:—For six azaleas, distinct, amatours, Mr. G. Wheeler, gardener to Sir F. H. Goldsmid, Bart.; for the like, nurserymen, Mr. C. Turner, of Slough; for best single specimen of azalea, open, Mr. A. Wilkie; for six cinerarias, distinct, open, Mr. J. Dobson and Sons; for six calceolarias, distinct, open, Mr. J. James; for twelve camellias, cut blooms, six kinds, open, Mr. A. Wilkie; for six camellias in flower, distinct, open, Mr. A. Wilkie; for nine auriculas, edged, disopen, Mr. A. Wikie; in inhome auriculas, selfs and fancies, distinct, open, Mr. C. Turner; for nine auriculas, selfs and fancies, distinct, open, Mr. C. Turner; for six cyclamens in flower, amateurs, Mr. J. Wiggins, gardener to W. Beck, Esq.; for bost miscellaneous collection of plants in flower, open, Mr. W. Bull. Of the calceolarias, the beautiful purple crimson flowers of the variety called Lord Elgin were most noticeable; and the cut camellias were very lovely. In Mr. Bull's collection there was amongst new and rare plants a very fine Pitcairnia tubulæformis, and a luxuriant Adiantum Farleyensis. Mr. Lane's very fine collection of plants in the corridor excited a good deal of notice.

VISIT OF THE CIVIL AND MECHANICAL ENGINEERS' SOCIETY TO THE SOUTH-ERN THAMES EMBANKMENT AND ST THOMAS' HOSPITAL.

UNDETERRED by all the disagreements of a very wet afternoon, the members of the above Society, including many visitors, made a tour of inspection, on Saturday last, of the works in progress on the south side of the Thames, from Westminster to Vauxhall-bridge. They were first conducted over the partially-erected hospital, examined and admired the plans, the design, the materials, and the workmanship, and visited the numerous sheds and temporary foci of industry attached to the permanent structure. Unfortunately, the day selected, and the hour at which the inspection took place, did not permit of the party witnessing the actual working of any of the machines calculated to lighten manual labour, and facilitate the dressing of the stone wall employed in the ornamental portions of the edifice. Some of the mouldings were of exceedingly beautiful proportions, and the workmanship of the stones was soadmirably performed that the lines and arrises were nearly as sharply defined as in the templets themselves. With the exception of the indispensable wooden fittings pertaining to windows, doors, and other interior accessories, the whole building may be considered fireproof, being composed of stone, brick, iron, and concrete. This precaution is all the more necessary, since a large number of the future inmates would be quite unable to assist themselves, in the event of a fire taking place. Those who are desirous of witnessing the improvement effected in this part of the metropolis, by the crection of this magnificent structure, should not content themselves by simply walking along the embankment, and viewing the river facade of the hospital, but should pass down by Stangate, and walk along Palace-road, which extends at present from Westminster to Lambeth-bridge, and will eventually debouch at Vauxhall. For sold dity of construction and width, this road will bear comparison with any in London.

and will eventually debouch at Vauxhall. For solidity of construction and width, this road will bear comparison with any in London.

The inspection of the hospital finished, the members proceeded to Lambeth, and viewed the nearly completed embankment, extending from that locality nearly to Vauxhall-bridge. The machine for cement testing was the first object claiming attention from those who had not seen its prototype at the Crossness Works, but as most of our readers are already familiar with the nature and use of this valuable little apparatus, there is no need of further comment respecting its duty and performance. At certain points along this portion of the embankment, there are openings to allow ingress and egress at low water into small docks. The roadway is carried over them upon castiron girders and brick arches turned from flange to flange, constituting a solid and permanent method of accomplishing the job. The entrance to the docks is, therefore, a short tunnel. Were we disposed to be critical, it might be remarked that there appeared to be rather a redundancy of metal in the girders, and their form and section were hardly consistent with scientific principles. At any rate, they are strong enough, which is being on the safe side, at all events. As there is no necessity for waiting for the paving of the roadway, it cannot be very long before the public have the benefit of this fine thoroughfare, instead of being at present compelled to make their way through the back alleys running parallel to the river from Lambeth to Vauxhall.

THE APPROACHING TRANSITS OF VENUS.

A N important question has been raised respecting the two transits of Venus, which were discussed at the Royal Geographical Society a few weeks ago. It may be remembered that Commander Davis, in describing the preparations which were to be made for Antarctic expeditions to observe the transit of 1882, quoted the statement made by the Astronomer Royal, that the transit of 1874 will be wholly unsuited to the particular mode of observation he was considering. This statement has now been called in question. M. Puiseux, a well-known French mathematician, and Mr. Proctor, the author of a treatise on the planet Saturn, have by independent processes, arrived at the conclusion that astronomers cannot do better than to apply to the transit of 1874 the old-fashioned and simpler mode of observation which Mr. Airy had rejected as unsuitable. A discussion of the nature of the famous problem of determining the sun's distance by observing Venus in transit would be much out of place in these columns. It may simply be stated that, as usually applied, the method resolves itself into a comparison of the durations of transit, as seen from a northern and from a southern station. The greater the difference of duration the more effective is the method. If one could find one station where the transit began as early as possible, and ended as late as possible, and another where these conditions were reversed, we should have precisely what is wanted. But astronomers have to be context with only an approach to these conditions, and it happens that in 1874 the approach will not be so close as could be wished. The Astronomer Royal, therefore, suggested that instead of sending out observers to places where the whole transit could be seen, we should send one set of observers to a place where the transit will begin as early as possible, another set to a place where the visit of sending out observers to places where the whole transit could be seen, we should send one set of observers to a place where the transit will begin as early as possible,

vitiate the resulting estimate of the sun's distance in an appreciable manner.

M. Pulseux has shown that the simpler method can be made use of effectively. He names places where the difference of the duration of transit is as much as 30min., whereas the greatest interval by the Astronomer Royal's method is but 22min. But Mr. Proctor goes much farther than this Indeed, Puiseux's reasoning is hardly sufficient, as Mr. Airy has shown, to establish the superiority of the simpler method. Mr. Proctor shows that by attending only to the particular appearances which observers are required to watch, the superiority of the simpler method is much more strikingly exhibited; and not only so, but that the transit of 1874 is shown to be clearly superior to the transit of 1882, and also to the famous transit of 1769. The appearances referred to are what are called the internal contacts of the planet with the sun. All calculations of the sun's distance have been founded on observations of the moments when the planet is just fully seen within the disc of the sun, after ingress, and before egress. Neither Mr. Airy nor M. Puis-ux seem to have paid sufficient attention to this circumstance. It now appears that whereas the greatest observed difference of duration was less than 24min., in 1769, and will be but 28min., at the outside, in 1882, it will be possible to find places in 1874 giving a difference of fully 36min. The full mathematical details of the correction are presented in the monthly notices of the Astronomical Society, and the next number of the "Quarterly Journal of Science" will contain a more popular statement of the facts which are in question. Fortunately, there is still time to make preparations for applying the simpler mode of observation suggested, should astronomers decide that Mr. Proctor's statements are valid. Antarctic journeys will have to be made to the very stations discussed by Commander Davis six weoks ago.—"Daily News."

### THE WATER WORKS OF ROUEN.

THE admirers of the French regime take an especial pleasure in the repetition of the somewhat hackneyed phrase, "They manage these things better in France." With all due deference to the occasional truth of this observation, there are very many matters which, in our opinion, we manage a great deal better in England. Among these are all works, particularly those on a scale of importance and magnitude, which are intended to improve the sanitary condition of our large centres of manufacturing and commercial industry. There are a from this from this few exceptions in France, but, as a general rule, the drainage and sewage of continental towns are a hostility.

mockery of all the laws of hygiene, and a total neglect of every consideration for the health and social comfort of the inhabitants. Gradually, foreign local authorities, and those upon whom rests the responsibility of all such measures, are awakening to the necessity of executing works of this description, and, in the first place, of ensuring an abundant and constant supply of pure and wholesome water. As a means of supply, wells, when they are in the vicinity of a town, are now regarded with universal suspicion, and springs that formerly sufficed for the inhabitants no longer afford an adequate yield for a population that annually increases in geometrical ratio. It is not sufficient to provide for the present. A liberal allowance must be made for future contingencies. It is scarcely necessary to enlarge upon the numerous causes that have tended to render indispensable a better supply of water to the majority of the English as well as the continental principal towns. In many, the recent establishment of breweries, paper mills, dye works, and other large industrial premises, have literally "swamped" the supply hitherto available, while the improved means designed for the extinction of fire cannot be adopted with success unless there be plenty of water at hand. These and other causes have mainly contributed to demonstrate that no town can expect to occupy a prominent position as a leading manufacturing or commercial centre if it should lack this essential characteristic of the progress of the times, and one so indispensable to its inhabitants.

commercial centre if it should lack this essential characteristic of the progress of the times, and one so indispensable to its inhabitants.

The corporation of one of the oldest towns in France, and one rich in historic associations, has recently taken action in this question, and authorized the ratepayers of Rouen to contract for a loan of £100,000, to construct water works that shall afford an adequate supply of water. In this instance we have the old story over again of uncertain and polluted sources, dried up in summer, overflowing in winter, but never at any time, in either summer or winter, fit to be drunk by man or beast. The platn upon which the city is situated is watered by the Seine and the rivers Aubette and Robec, but they are all strongly contaminated by the centents of sewers and the innuncrable miscellaneous abominations and refuse that are poured into them from the different manufactories established upon their banks. Another serious and insurmountable evil is that the level of the River Seine at Rouen is only 3ft, higher than that of the sea. There is therefore not sufficient fall to carry away the impurities that are incessantly launched into the stream. Besides, the tide rises some distance up the river, so that there is a continual come-and-go movement, which amalgamates the whole mass of filth, and renders the water little better than a slow poison. The rivers Aub-tte and Robec are pretty much in the same condition, so that it is idle to think of any of these three constituting a proper source of supply. As may be imagined, when the rivers are so foul, there is not much to expect from the wells in their neighbourhood, and the only chance left to the inhabitants is what they can catch and store in cisterns and reservoirs. So long as there is plenty of rain this plan succeeds tolerably well, "faute de mieux," but in time of drought then come the deprivation and suffering. During the long-continued drought of last year these supplies were totally exhausied, and water was so searce and diffic

it was sold in the higher parts of the town at sixpence a small cask. When so high a price was paid for a supply of this necessary for drinking and culinary purposes, it can be readily anticipated that very little found its way into the sewers. They were therefore left unflushed, deposits accumulated in them, and from their putrefaction arose cultuvia and emanations which threatened at one time to

occasion a serious epidemic. Ever since, the inhabitants have been alarmed at the possibility of

inhabitants nave been aramed at the possibility of this calamity occurring at some future period, and so much pressure was brought to bear upon the local authorities that they have at last set themselves to work in good earnest to radically cure the

Making the most of the old sources of supply, they were equal to 400,000 gallons per diem, and it is now proposed to furnish a daily supply of 3,000,000 gallons. Although it would not be possible, with a due regard to the purity and potable nature of the water, to use the Robec as a source in its course through the town, yet there would manifestly be no objection to making it available by taking the water at a higher level, where it would be uncontaminated. Three of these sources exist at a distance of four or five miles from Rouen, and have an elevation of 220ft, above the mean sea level. They flow out of the side of a chalky hill, and yield on an average 60 gallons per second. In seasons of drought the supply is about 30 gallons, and during floods nearly 90 gallons per same unit of time. To obtain the quantity already mentioned for the daily requirements of the town, it would be necessary to impound, in time of drought, the whole of the supply from this source. Against this proposition the inhabitants of the valley of the Robec very naturally protested in the strongest terms of indignation and hostility. Fortunately for the projectors and

Digitized by Google

advocates of the new undertaking, as well as for the residents in Rouen, there are other sources, in different parts of the valley, which can be made use of without interfering so seriously with the interests of the cultivators of the soil. It was also discovered during the preliminary investigations and examinations of the locality that took place consequent upon the discussion of the question, that an additional supply of 20 gallons per second could be obtained from the three sources first contemplated by lower-ing the outflow or mouth of exit without interfering ing the outflow or mouth of exit without interfering with the rights of the present land occupiers. Another piece of information was likewise elicited which was of very material importance. It was ascertained that underneath the hills encircling the town was situated a vast bed of chalk, free upon the upper surface, and containing in its innumerable crevices and fissures a large supply of water, continually renewed by rain and infiltration. To drain this bed in order to reach the source all that is required is to construct a tunnel, which at the same time could be used for the reception of the same time could be used for the reception of whatever amount of water it might be determined to take from the river Robec. After mature and deliberate consideration of the proposed scheme, the chief authorities of State decided that the mouth of centerate consideration of the proposed scheme, the chief authorities of State decided that the mouth of the outflow might be lowered and the tunnel constructed, but that no supply was to be drawn from the Robee above the level of such altered outflow until the tunnel was completed and all the water obtained that could be procured by the tapping of the chalk stratum. It is also provided that whatever quantity of water may be taken for the use of the town there must be a minimum supply, even in times of drought, of 10 gallons per second secured to the inhabitants of the valley, and an indemnification granted to them for any loss they may sustain from being reduced to so small a supply. Ten years are allowed for the repayment of the loan, but there is no doubt that if the anticipated supply can be obtained there will be little or no difficulty in procuring ample funds for that purpose.—"Building News."

### LOCAL ATTRACTION.

COLONEL SIR HENRY JAMES, Director-General of the Ordnance Survey, reports that during the past year inquiry has been prosecuted observes that the relative extent to which the plumb line and the levels of our astronomical instruments are affected in a country where there is nothing on the surface of the ground to account for it, may be judged from the fact that it is nearly double the amount of the deflection on Schehallion mountain, 3,547ft. high, with the instrument placed on the sides of the mountain that the mountain the structure of the sides of the mountain that the mountain of the sides of the mountain that the mountain that the mountain the sides of the mountain that the mountain the sides of the mountain that the sides of the sides of the mountain that the sides of the itself, at one-third of its allitude, the position to produce the greatest effect from the mass of the mountain on the plumb lines. He considers that we have very decided indications that the cause is in the granitic rocks which extend in a south-west direction from Cowhythe through Banffshire, and which are highly impregnated in some parts with magnetic iron in a metallic state. The range of mountains on the south-east of Banffshire culminates in Ben Muich Dhui, 4,295ft. high, which, after Ben Nevis, 4,406ft. high, is the highest mountain in Scotland. The great amount of the attraction at Cowhythe, and along the coast to the east and west of Portsoy, cannot be explained by anything visible on the surface, and obliges us to imagine the existence of some large and very dense mass of matter underneath it. Sir H. James hopes to resume this important inquiry this season; and the geological structure, as well as the mineral character, of the rocks, will be carefully investi-gated by the Director of the Geological Survey of Scotland.

SCIENCE AND ART .- A striking instance of the SCIENCE AND ART.—A striking instance of the immense value a small piece of steel may acquire by the great power of skilled mechanical labour is the balance-spring of a watch. From its extreme fineness and delicacy, 4,000 weigh not more than one ounce, and exceed in value £1,000. A most interesting little work, describing the rise and progress of watchmaking, has been published by J. W. Benson, 25, Old Bond-street, and the City Steam Factory, 58 and 60, Ludgate-hill. The book which is profusely illustrated, gives a full description of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointtion of the various kinds of watches and clocks, with their prices. Mr. Benson (who holds the appointment to the Prince of Wales) has also published a pamphlet on Artistic Gold Jewellery, illustrated with the most beautiful designs of Bracelets, Brooches, Earrings, Lockets, &c., &c., suitable for Wedding, Birthday, and other presents. These pamphlets are sent post free for two stamps each, and they cannot be too strongly recommended to those contemplating a purchase, especially to residents in the country or abroad, who are thus enabled to select any article they may require, and have it forwarded with perfect safety.—[ADVI.]

# COURT OF COMMON PLEAS. April 16.

(Sittings in Banco, before Lord Chief Justice BOVILL and Justices KEATING and SMITH.) EDMUNDS v. GREENWOOD.

It is hardly necessary to remind our readers that this action was brought by Mr. Edmunds, the late Clerk of the Patents, to recover damages for libel; and the statements complained of occurred in reports made by Messrs. Hindmarch and Greenwood to the Commissioners of Patents. When the case was down for trial, an agreement between counsel was come to that the matter should be referred to arbitration, but in consequence of some misunderstanding the agreement was not carried

Mr. Digby Seymour, Q.C., on the part of the plaintiff, now moved for a rule calling upon the defendant to show cause why the case should not be restored to the paper, and an early day fixed for the trial; and why the defendant should not pay the costs of the day, which had been rendered useless by the record being withdrawn. The learned counsel said that the action was commenced at the end of 1866, and on October 16. 1868, Mr. Sclater-Booth wrote agreeing to terms of reference. A long correspondence followed, but no reference was brought about, and in January last the case again stood for trial. A day or two before the trial, counsel again agreed to a reference, "The reference to be on the footing of Mr. Sclater-Booth's letter of October 16, 1868, subject to the following change in section 4. The section to run thus:—Their lordships are willing to abide by the offer made to you and declined by you in 1867, namely, that you should bring before the arbitrators any substantial claims which you may desire to make on legal or moral grounds against the Crown, the arbitrators to have power in relation to any such claims to make a recommendation to the Government having regard to all the circumstances of the case. Stet processus of action without prejudice to any claims Mr. Edmunds may make against the Crown in consequence of the reports of Messrs. Greenwood and Hindmarch." A formal deed of submission to arbitration was thereupon drawn up, and it stated, "That any claims which the said Leonard Edmunds may make against her Majesty the Queen in consequence of the reports of the said Messrs. Greenwood and Hindmarch, and the said two papers, shall be referred to the award of the arbitrators, and they may make any recommendation to her Majesty the Queen in respect of the premises in this paragraph set forth." This deed, however, was not acceded to on behalf the defendant, his advisers wishing to state in it that the arbitrators might consider the plaintiff's claims in reference to the reports, "provided the arbitrators shall think fit to entertain them, and the plaintiff declining to accept any variation in the terms of reference." The matter still stood in this position, and the learned counsel said that the plaintiff, who always had been and still was anxious to have his case tried by a jury, had no alternative but to make the present motion.

The Lord Chief Justice suggested that the rule should be to show cause why an order of reference should not be drawn up embodying the terms of agreement for reference signed between counsel for plaintiff and defendant, or why the agreement should not be cancelled, and the cause restored to its place in the list, and appointed for the first sitting day after Trinity Term; and why the defendant should not pay the cost of the day. He apprehended that as soon as the matter came again into the hands of counsel they would have no difficulty in coming to an agreement.

A rule was granted in the terms suggested by his lordship.

# ROLLS COURT. April 21.

(Before the MASTER OF THE ROLLS.) DAW v. ELEY.

THIS was the hearing of a suit to restrain the de-This was the hearing of a suit to restrain the defendants, Messrs. Eley, from manufacturing or selling cartridge-cases for breech-loading firearms, in infringement of the plaintiff's (Mr. G. H. Daw, of Threadneedle-street) patent, for improvements in the manufacture of such articles, by making them of a metal tube, formed from a strip of thin rolled sheet-metal, bent into a tubular form, and

having its overlapping edges soldered or cemented together, so as to form a perfect tube.

Our readers will remember that, in consequence of the failure of what is known as the "Boxer Service Cartridge," the Secretary of State for War offered a prize of £400 for the 500 best cartridges, to be produced by a given day, upon certain conditions. The plaintiff, G. H. Daw, competed for the prize, and won it by means of his cartridge, the cases of which formed the subject of the patent which Messrs. Eley was alleged to have infringed, by making and selling a case of brass, lined with paper or thin pastoboard, made in accordance with what is known as Rochatte's patent, of which they are the proprietors. The case occupied nearly two days

Mr. Manisty, Q.C., Mr. Jossel, Q.C., Mr. Mac-rory, Q.C., and Mr. Russell Roberts appeared for the plaintiffs; Mr. Grove, Q.C., Mr. Southgate, Q.C., Mr. Theodore Asten, and Mr. Langley for the defendant.

After hearing Mr. Manisty, Q.C., in reply, His Lordship reserved judgment.

# AN HERCULEAN FEAT.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—"The intended revolutions of the engines of Sir.—"The intended revolutions of the engines of the Majesty's steamship 'Hercules' is put down at 65." This agrees nearly with the pitch of the screw, so as to attain a speed of vessel of 16.3 knots per hour without slip. It has been stated that the engines would develope six times their nominal power going at the intended revolutions. Now, as the nominal power is found by the formula

Area of cylinder × 7lb. × speed of piston 33,000,

33,000, it follows that the actual force on the piston per square inch should be six times the nominal measure of 42lb. Shade of Watt! what have we here! An engine, without any cap on the valve, working up to the full boiler pressure to the end of the stroke. Are we in our second childhood? Have we become so obtuse that this rubbish is thrust down our throats in this the nineteenth century? Thank our stars, no; for technical education is fully appreciated, and we are above such devices, which can only tend to mystify the uninitiated.—I am, Sir, yours, &c., April 20.

Detector.

# SHIPS OF WAR.

SIR,-In a letter which appeared in your last number, under the above heading, your correspondent asks "whether guns are to be trained in a revolving turret, on a broadside, in fixed central turrets, &c., etc., with Captain Scott's system, Armstrong, the Moncrieff gun carriage, or how?" and proceeds to urge the adoption of the twin screw mode of propulsion, or, as he says, "my twins," which he describes as being a better form than originally demonstrated by the late Mr. Rennie, C.E.

I am pleased to observe that Mr. Winton inclines to the belief that the twin screw system is well adapted to vessels of war of a large class, but he should bear in mind that this opinion was long since held and specially advocated by Captain T. E. Symonds, R.N., and the late Mr. Richard Roberts, number, under the above heading, your correspondent

should bear in mind that this opinion was long since held and specially advocated by Captain T. E. Symonds, R.N., and the late Mr. Richard Roberts, C.E.; likewise by Captain Selwyn, R.N., and the Messrs. Dudgeon. However, I do not propose to follow Mr. Winton in detail, on the peculiar form of the ship he has shown, as I cannot perceive any practical advantages over the ordinary form—unless his object is to reduce the stowing capacity—which is seldom in excess of that required.

As to the proposal for "conical fixed turrets to suit the Moncrieff system," however admirable that system may be for other special purposes, the turret would require to be open at the top, to enable the

system may be for other special purposes, the turret would require to be open at the top, to enable the gun to be brought up in position to bear on its adversary, and, therefore, unprotected from vertical first If such a vessel were ever sent to sea, and met with a foe, I am afraid she would receive different treatment to that which Mr. Winton appears to think; for apart from other casualties which are likely to occur in such a vessel, it is most probable that either a stink-part live shell, or other unwelcome missiles. occur in such a vessel, it is most probable that either a stink-pot, live shell, or other unwelcome missiles, would find its way direct into the turret, and thus speedily and effectually silence the gun, and most probably end the career of such a ship.—I am, Sir, yours, &c.

F. H. R.

ANOTHER telescopic planet has just been discovered by M. Luther, at the observatory of Bilk. It is the 10sth of the series of those existing between Mars and Jupiter, and resembles a star of the 11th magnitude. The 107th was discovered in December

### TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 is. 8d. yearly, or 10s. 10d. half-yearly, payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. B. Smiles, MECHANICS MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communi-cations unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the MEGHANICS' MAGA-ZINE, at the rate of 6d, per line, or 5d, per line for 13 inser-sons, or 4d, per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate Special arrangements made for large advertise

# Habal, Military, and Gunnery Items.

THE Emperor of Austria has conferred the Order of the Iron Crown of the third class on Dr. Petermann for his services rendered to science in his expedition to the North Pole, and the Cross of Chevalier of the Order of Francis Joseph on Captain Koldewey, the naval chief of the same.

A RUMOUR has reached us that the Government intends to continue the present Snider breech action with the Henry barrel in the military arm of the future. We do not youch for the truth of the report, but it comes to us from a quarter in which such say ings generally have some foundation.

The oldest of the Austrian generals, Baron de Lebzeltern, has just died at the age of 83. The distinguished veteran served in the campaigns of 1811 and 1813, and the Archduke Charles confided to him the military education of his sons. After sixty years of active service the baron became governor of the military school and president of the high military court of Austria. He was a personal friend of the Duke of Wellington.

His Majesty, the King of the Netherlands, has awarded the following rewards:—To Captain Dunn, master of the fishing smack "Criterion," a silver medal, certificate, and £6; J. Bains, pilot, a certificate and £3; P. Larsen, seaman, a certificate and cate and £3; P. Larsen, seaman, a certificate and £2 10s.; J. Rowen, seaman, a certificate and £2 10s.; A. Lorensen, boy, a certificate and £1. These persons were instrumental in saving the lives of the master and crew of the Dutch fishing vessel. Grietje." when that vessel was wrecked upon the Dogger bank, December 1, 1868.

bank, December 1, 1868.

The following vessels are now in course of construction for the Royal Navy:—The "Bittern," gun vessel, Pembroke; the "Briton," corvette, Sheerness; the "Bulwark," screw ship, Chatham; the "Hotspur," ram, Glasgow; the "Invincible," iron ship, Glasgow; the "Iron Duke," iron ship, Pembroke; the "Robust," screw ship, Devonport; the "Swiftsure," armour-plated ship, Jarrow; the "Tenedos," sloop, Devonport; the "Thalia," corvette, Woolwich; the "Triumph," iron ship, Jarrow; the "Vanguard," armour-plated ship, Birkenhead; and the "Vulture," gun vessel.

Anneren is a correct list of the French navy at

-Frigates 9, cor-241. 3. Paddle-wheel steamers.vettes 7, avisoes 35—total, 51. 4. Sailing ships.—Ships of the line 2, frigates 10, corvettes 6, brigs 5, brigantines 12, cutters 19, lorchas 7, peniches 7, great boats 7, transports 25—total, 100. Recapitulation.—Ironclads 63, screw-steamers 241, paddle-wheel steamers 51, sailing ships 100.—General total 455.

The quarterly meeting of the members of the Royal Naval Benevolent Society was held the other day at Willis's Rooms, King-street, St. James's, Admiral the Earl of Lauderdale in the chair. The report showed a balance from last quarter of £236 0s. 4d.; dividend and interest, £650 7s. 6d.; subscriptions and donations, £434 16s. 1d.; the expenses amounted to £713 15s. 11d., leaving a balance respecting the admission of assistant paymasters to respecting the admission of assistant paymasters to participation in the benefits of the society. It was ultimately decided that they should be admissible. The report was then adopted, and the proceedings closed in the usual manner.

A TRIP down the river to Erith was made on A TRIP down the river to Enth was made on Mednesday, in a steam launch just finished, by Messrs. Yarrow and Hedley, of Poplar. Her length is 35ft.; beam, 6½t.; engines, 5-horse power; speed, 8½ miles per hour. For navigation, one man and a boy is all the crew required, but the boat will carry sixteen or eighteen persons. On the voyage, the saloon steam launch under construction in the buildsaloon steam launch under construction in the outling yard at Poplar was visited. The length of this launch is 40ft.; engine power, 7 horses nominal; estimated speed, 9 miles an hour. These boats are well suited for river and canal navigation, and it is very possible that we may hear of them hereafter on the Nile or the African lakes.

Moses Dyer, who enlisted in the 2nd battalion MOSES DYER, Who enlisted in the 2m battain 30th Regiment, about the year 1801, died at Tetsworth, Oxfordshire, on Saturday, having served in Spain and Portugal, and received the war medal, with clasps for Badajoz, Cuidad Rodrigo, &c., also a medal for Waterloo, where he was severely wounded medal for Waterloo, where he was severely wounded in the ribs. He had completed his 86th year all but one month; a widow and children, and graudchildren survive him; the former being without any means of support, and having reached an advanced age, the benevolent may feel disposed to contribute even a trifle for her benefit. The eldest son of Mosse Dyer, was in the 86th Regiment in eleven engagements during the Indian mutiny, and from the effects of the campaign, suddenly dropped dead on board ship on the return passage to England. on the return passage to England.

A LETTER in the "Journal de Liege," dated from A LETTER in the "Journal de Liege," dated from Longwy, says:—" We hear much of the conveyance of troops, arms, and munitions of war by the Eastern Railway. I can speak as to the fortress of Longwy. The effective strength of the garrison has Longwy. The effective strength of the garrison has never been so small—only two companies of infantry and about a score each of artillery and cavalry. But, on the other hand, the magazines are crammed with on the other hand, the magazines are crammed with stores. The old stock of powder has been renewed, and nearly 6,000 kilogrammes of fresh powder have been received within a month, the old guns have been replaced by rifled cannon on the newest system, the loopholes for musketry, closed for many years, have been reopened, and the number of guns, which was five in each bastion, has been increased. Vast was not in each bastion, has been increased. Vast stores of freshly-made biscuit have been accumulated, and the works on the ramparts are being pushed on with the greatest activity. With Metz and the other frontier fortresses it is the same."

# Miscellanea.

A BILL to amend the law relating to Post-office A BILL to amend the law relating to Fost-onice Savings Banks proposes that the Postmaster-General may direct his officers to receive from any one depositor sums amounting in the whole to not more than £100 in any one year, and not more than £300 in any number of years.

THE partnership hitherto existing between Messrs. Wallis, Haslam and Steevens, agricultural engineers, of Basingstoke, has been dissolved on the retirement of Mr. Haslam from the firm, and the business will in future be carried on by Messrs. Wallis and Steevens. A valuation of the partnership property has been made by Mr. Robert C. May and Mr. T. C. Hambling, of Westminster.

THE number of visitors to the South Kensington THE number of visitors to the South Kensington Museum during the week ending April 17, 1869. was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 12,407; Meyrick and other galleries, 2,526; on Wednesday, Thursday, and Friday (admission 6d.) from 10 a.m. till 6 p.m., 2,292 Meyrick and other galleries, 193; total, 17,418. Average of corresponding week in former years, 11,233. Total from opening of Museum, 8,355,787.

Jarrow; the "Vanguard," armour-plated ship, Birkenhead; and the "Vulture," gun vessel.

Annexed is a correct list of the French navy at the present time:—1. Iron-clad fleet.—Ships of the line 2, frigates 19, corvettes 9, cruisers 7, floating batteries 26—total, 63. 2. Screw steamers.—Ships of the line 15, frigates 18, corvettes 21, avisoes 60, gun boats 70, transports 55, special ships 2—total, 28; Salford, Bradford, Hull, and The "Medical Times" states that there was a case

The Lord President of the Council has requested The Lord President of the Council has requested Sir Charles Wheatstone, Sir Michael Costa, Professor Tyndall, Lieut. Colonel Scott, R.E., Captain Donnelly, R.E., and Mr. Bowley, to report on the acoustics of the new lecture theatre at South Kensington. There will be three trials, one by a lecture, with demonstrations, on musical pitch, by Professor Guthrie; a second by voices, directed by Mr. A. Sullivan; and the third by instruments, directed by Mr. Ella. Mr. Ella.

As August 27, 1870, will be the centenary birthday of the great German philospher Hegel, the Philosophical Society of Berlin have issued an appeal for subscriptions for a monument to the distinguished subscriptions for a monument to the distinguished thinker. Dr. Matzner has addressed himself to Dr. J. H. Stirling, Piershill, Edinburgh, the author of "The Secret of Hegel," to request his co-operation in the work of collecting the desired funds in Great Britain; and Dr. Stirling has announced in the "Edinburgh Courant" his willingness to receive and acknowledge any contributions sent him to be for-warded to Berlin.

THE number of hogs packed in the Western States THE number of hogs packed in the Western States in 1868-9 was 2,477,264, as compared with 2,781,084 in 1867-8; 2,490,791 in 1866-7; 1,705,855 in 1865-6; 2,429,779 in 1864-5; 3,261,105 in 1863-4; 4,069,520 in 1862-3; 2,895,666 in 1861-2; 2,155,702 in 1860-1; and 2,350,822 in 1859-60. The weight of the pork thus packed was computed at 512,174,332lb. in 1868-9 as compared with 561,399,432lb. in 1867-8. The as compared with 561,399,43216. In 1867-8. The 2,477,264 hogs packed in 1868-9 were contributed by the following States:—Ohio, 544,651; Illinios, 806,033; Indiana, 326,658; Kentucky, 183,426; Missouri, 361,067; Wisconsin, 129,094; and Iowa, 126.335

126,335.

The result of the final appeal on the long litigation between the North-Eastern Railway Company and Mr. George Hudson was to confirm the reversal of the decision of the Master of the Rolls, and reduces Mr. Hudson to a state of penury. He is now in France, said to be utterly destitute. In addition to a subscription to meet present wants, and in the belief that the "Railway King" was as much "sinned against as sinning," a large shareholder has intimated his intention to ask his co-partners in the North-Eastern Company to grant to Mr. Hudson an annuity of £200 a year. An interesting discussion is looked for at the next general meeting, and many believe the feeling will be in favour of the project.

In the nine months ending March, 1869, the revenue of the Clyde Trust amounted to £106,105, as compared with £101,935 in the corresponding period of 1867-8, showing an increase of £4.170. For the whole of the financial year 1868 the revenue of the Trust was £143,840, as compared with £97,983 in 1860. £64,243 in 1850, 46,536, in 1840, £20,296 in 1830, and £6,328 in 1820. The Customs are constant and the financial years £1,167.53 £97,983 in 1860. £64,243 in 1850, 46,536, in 1840,  $\pm$ 20,296 in 1830, and £6,328 in 1820. The Customs revenue collected at Glasgow in 1868 was £1,106,753 as compared with £883,981 in 1860, £645,669 in 1850, £472,563 in 1840 £72,053 in 1830, and £11,428 in 1820. The population of Glasgow in 1868 was estimated at 515,412, as compared with 395,251, in 1860, 333,657 in 1850, 270,486 in 1840, 202,426 in 1820, and  $\pm$ 147,043 in 1850. 1830, and 147,043 in 1820.

RECENT communications from Adelaide, South Australia, have made known the discovery in the Southern portion of the colony of a remarkable carboniferous substance, which hitherto has only been found in small quantity in the coal strata of Derbyshire. It is a "mineral caoutchouc," so called from its general appearance and some elasticity. In Australia it is found on the surface of the sandy soil, through which it would appear to exude from beneath, as, burnt off occasionally by the bush fires, it is again found after the winter season occurring in quantity and of various thick, nesses. Analysis proves it to contain 8-2, or more per cent. of a pure hydro-carboniferous oil; its RECENT communications from Adelaide, nesses. Adatysis proves it to contain 5.2, or hade per cent. of a pure hydro-carboniferous oil; its value for gas-producing purposes would therefore be great, and it is also believed to be applicable to the manufacture of certain dves.

manufacture of certain dyes.

From a description given by the "Alta California' of the works adopted by the Central Pacific Railway to protect the line from the heavy falls of snow to be expected in certain sections, it appears that a shed covering has been erected 22 miles in length. This shed is 16ft. in width and 16ft. in height, not including the pitch of the roof. It is put up in the most substantial manner, all the timbers used being of the best quality to be obtained. The sides are enclosed, and were it not for the fact that day light penetrates through the interstices between the boards, the whole would be like a huge tunnel. The building is braced together in a peculiar manner, and is, in addition, firmly bolted to the rocks near the face of a cliff, Where snow slides are to be feared, an extension of the roof has been carried to the cliffs, so that falling masses shall pass over the

of compound fracture so offensive that it defied the effects of ventilation and the usual disinfectants. The wound was covered with dry earth, the odour The wound was covered with dry earth, the odour was absorbed, and with the abatement of this came a speedy improvement in the character of the wound. Encouraged by this result, Dr. Hewson has applied it with marked success in the treatment of every other disease attended with profuse and offensive suppuration—ulcers of the legs, contused and sloughter wounds guarded twenty several burns capacity. ing wounds, gunshot wounds, severe burns, cancer. In all these it is said to have succeeded beyond expectation, and it is now proposed to apply it to smallpox, the most offensive and virulent of all

An important discovery of old Scottish coins was recently made in a field near Prestonpans. There were in all 114 coins, chiefly silver, dating from the reign of James III. to that of Mary. The coins were lying in a heap, as if they had been originally in a bag. Among them was a gold noble of the time of Mary. One of the silver pieces had been struck in commemoration of Mary's marriage with the Dauphin of France. It is dated 1558, and in the Dauphin of France. It is dated 1558; and in addition to the monogram, "F.M.," with the heraldic emblems of France and Scotland, there is heraldic emblems of France and Scotland, there is the following Latin legend on the reverse—"Jam non sunt due sed una caro." One of the silver coins, bearing the date 1558, is said to be almost as perfect in its stamping as on the day when it left the Scottish mint. A number of the coins have been deposited in the Edinburgh Antiquarian Museum. Carberry-hill, the scene of Mary's surrender, which is in the neighbourhood of the place where the discovery was made. covery was made.

THE buffaloes found in the telegraph poles of the overland line a new source of delight on the treeless prairie—the novelty of having something to scratch prairie—the novelty of having something to scratch against. But, observes an American paper, it was expensive scratching for the telegraph company, and there, indeed, was the rub, for the bisons shook down miles of wire daily. A bright idea struck somebody to send to St. Louis and Chicago for all the bradawls that could be purchased, and these were driven into the poles with a view to wound the were driven into the poles with a view to wound the animals and check their rubbing propensity. Never was a greater mistake. The buffaloes were delighted. For the first time they came to the scratch sure of a sensation in their thick hides that thrilled them from horn to tail. They would go 15 miles to find a bradawl. They fought battles around the poles containing them, and the victor would proudly climb the mountainous heap of rump and lump of the fallen, and scratch himself into bliss until the bradawl broke or pole came down. There has been no demand for bradawls from the Kansas region since the first invoice. since the first invoice.

# Matents for Inbentions.

# ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

3040 E. T. Bellhouse and W. J. Dorning, Manchester.

Hydraulic presses. Dated October 6, 1868.

In presses constructed according to this invention, three rams, with their respective cylinders, are employed in one arrangement. The rams and cylinders are ranged in line one with the others, the two outer rams and cylinders being of a length suitable to the entire lift of the press table. The centre cylinder is made suitable for a ram of a greater diameter than the two outer rams,

the stroke of which is considerably less than that of the outer rams. The central cylinder is cast in one portion with the lower cross piece of the press, or, if found more convenient, the cylinder may be separately formed, as in the case of the outer cylinders. When the compression of the cotton or other material is commenced, the two outer rams are forced up by the pumpr, the central ram remaining stationary. The action of the outer rams continues until a greater pressure than the said outer rams can communicate is required. An intermediate piece is then placed between the upper part of the central ram and the lower part of the central ram and the lower part of the press table or follower, and the three rams are forced up simultaneously to produce the final compression. The intermediate piece is preferably formed of metal, and of a form similar to an ordinary press ram, and is suspended from a crane awivelling around one of the press columns, or from a carriage running on rails. In place of the arrangement just described, three or more rams, each having the full stroke or lift of the press table, may be employed, in conjunction with a ram of a larger diameter, having a short stroke, fitted or provided with an intermediate piece may be employed, in conjunction with other means, for effecting the first portion of the compression.—Patent completed.

3041 E. Simons, Sheffield. Railway brakes. Dated the stroke of which is considerably less than that of the

3041 E. SIMONS, Sheffield. Railway brakes. Dated

3041 E. Simons, Sheffield. Railway brakes. Dated October 6, 1868.

The patentee proposes to mount or otherwise support upon a bracket, or in a box, conveniently placed in the carriage, van, or vehicle, a catch, and a circular or segmental catch or indented plate, to which plate, or to its boss, a chain dependent therefrom is secured, capable, when the circular plate is partially turned, of winding up or folding the chain upon its boss or drum. To the lower end of the chain a rod is suspended transversely, to which are secured (immediately over the rails or metals) shoes or curved brake blocks. Two surfaces of these shoes when lowered fit the periphery of the wheel and the plane of the metals, so as to drag upon and prevent the revolution of the wheels. A flange is provided in order to keep the shoes or blocks in their position on the metals. The transverse rod and blocks or shoes are governed in their movements by means of curved slots, formed concentrically or parallel to the periphery of the wheels, in brackets, secured to the sides of the carriage, or to the axle or axle hox, and in such a position that when the catch wheel is slightly turned or wound up, so as to be caught and retained by the lever catch, the shoes or blocks, through the medium of the chain, are elevated or raised from the metals or rails. The concentric groove governs the position of the rod and blocks, clears them out of contact with the wheels, but when lowered the blocks are brought to bear upon the rail, so as to form an abutment for the wheels abut when lowered the blocks are brought to bear upon the rail, so as to form an abutment for the wheels.

3042 N. TCHEPELEVSKY, Moscow. Enamel. (A communication.) Dated October 6, 1868.

The enamel consists of two separate solutions, first, a warm solution of animal size, with the addition of glycerine and white alum. Second, a chemical production invented in Russia and known there as "Rumstedts Verdine," consisting of a mixture of sulphate of potash and sulphate of chromium, dissolved in cold water—Patent abandoned.

and sulphate of chromium, dissolved in cold water.—Patent abandoned.

3043 J. R. Wigham, Monkston, Ireland. Illuminating lighthouses. Dated October 6, 1868.

This relates to patents dated respectively April 4, 1865 (No. 945), and November 6, 1866 (No. 2871). It consists in illuminating lighthouses by means of combustible gases, prepared from coal, coke. or other similar carbonaceous substances, in a more or less pulverized state, and mixed with paraffin, petroleum, or shale oil, or other liquid or semi-liquid hydrocarbons, and also from peat, saw dust, and other similar vegetable matters, either alone or mixed with oil, paraffin, shale oil, petroleum, or other liquid or semi-liquid hydrocarbons. It also consists in an improved apparatus for the manufacture of illuminating gas, for the use of lighthouses, or for other purposes. The retorts, for the destructive distillation of the coal or other gasmaking material, are arranged in a horizontal position, each retort being somewhat arch-shaped, having in its interior surface near the spring of the arch a projecting fillet, in order to support a movable arched cast or wrought iron lining or partition, so constructed in one, two, or more pieces, that when placed in their proper positions they will have the effect of causing the greater part, if not all, of the gas distilled from the coal or other gasmaking material to pass under and over them.—Patent completed.

3045 F. S. GILBERT and W. G. WHITE. Laurence Pountney-lane, E.C. Self-adjusting spanners. Dated Oc-tober 6, 1868. These spanners are made of two bare of the

tober 6, 1868.

These spanners are made of two bars of iron, or any other suitable material, one longer than the other, with a jaw at the top of each bar. The shorter bar is placed in front of the longer one, so that the front bar jaw comes below the back bar jaw. The front part of the back bar is made with a male dovetail, and the back part of the front bar with a female dovetail, to correspond, for the front bar to slide on. At the bottom of the front back bars a lever, made to any convenient angle, is attached by means of joints.—Patent abandoned.

3046 A. G. STRAKER, Leadenhall-street, E.C. Samplebag for post. Dated October 6, 1863

An envelope or bag open at end or side with a flap, having two, three, or more lappets, is made or formed out of paper, linen, canvas, or any other material, all being gummed in either one or more operations. The under side of the flap is gummed or cemented.—Patent abandoned.

3047 B. RAMSEY, Wimpole-street, W. Knee caps for horses. Dated October 6, 1868.

This consists in forming knee caps for horses of soft vulcanized india-rubber, moulded or shaped to casts of those parts of a horse's leg to which they are intended to be applied. The knee caps are made of one entire piece of material, which is passed over the horse's foot to the desired part of his leg, which it surrounds and embraces, holding it securely in position, partly by its elasticity and partly by its shape, and allowing freedom of movement to the leg.—Patent completed.

3048 T. GARNETT, Smethwick. Hydraulic rams. Dated betober 6, 1868.

An induction and exhaust valve are formed both of

which are contained in the piston. The lifts of these valves are regulated by the seats. The seats of the escape valve and the induction valve are formed in the piston, each valve having two faces, one on the seat and the other off, thus closing the passage to one side of the piston and opening it to the other. The pressure is admitted by a pipe communicating with the induction valve, such pressure being prevented from escaping into the cylinder by means of packings. As soon as the pressure is admitted, the induction valve closes the passage to one end of the piston, thus opening the passage at the other end; the pressure being on one end of the pressure to the cylinder, until the spindle of the induction valve comes in contact with a regulating pin, and opens the passage to the opposite end of the piston; the pressure closing the exhaust at that end, and opening it at the other, allowing the exhaust at that end, and opening it at the other, allowing the exhaust to escape into an exhaust passage, which is formed through the length of the double piston rods, and connected with the exhaust valve. A reciprocating motion is thus obtained, or a series of strokes, given by the piston from side to side, or upwards and downwards, as may be required.—Patent completed. The lifts of these which are contained in the piston. The lifts o

and downwards, as may be required.—Patent completed.

3049 H. STEFFANSON, Gefieborgs Lan, Sweden. Sawing

secod. Dated October 6, 1868.

The object is to equalize the motion of saw frames by
checking or counteracting the momentum of the frame,
and using the power thus acquired to drive the frame in
the opposite direction. The invention consists in providing an elastic cushion to receive the shock of the crosshead of the reciprocating saw frame at each end of the
stroke. This elastic cushion may be formed either of a
body of air, steam, or gas contained in a cylinder or
cylinders, or india-rubber or metallic springs may be
employed instead.—Patent abandoned.

employed instead.—Patent abandoned.

3050 J. G. WILLANS, St. Stephen's-crescent. Manufacture of iron and steel. Dated October 6, 1868.

The first improvement is to supply chemical salts or other solution, not for the purpose of depriving the metal of carbon, but of such a nature as to combine with or neutralize the sulphur or phosphorus in the metal, so that in melting or manufacturing the injurious effects of these elements may be removed or lessened. The second improvement is to remove the greater part of the cinder from the granules after they are brought into the malleable condition, and before they are hammered or compressed together, and then to compress the granules or particles into moulds or shapes to produce articles of iron, or it may be of steel, possessing greater strength than if made of cast iron. The third improvement is, first, to heat the granules and oxide together in one place, removing them thence before the granules are molten, and then melting them with cast iron, charcoal, or other materials commonly used by steel melters.—Patent completed.

3051 J. ASPINALL, Harrow. Telegraphic cables. Dated

3051 J. ASPINALL, Harrow. Telegraphic cables. Dated

3051 J. ASPINALL, Harrow. Telegraphic Cocces.

October 6, 1868.

Telegraphic ropes or cables are formed of hair or animal fibre. Or, where hemp or vegetable fibre is used, then, in order to protect the telegraphic or other rope or cable, the rope or cable is enveloped in felt or other fabric made of animal fibre. The felt or fabric is preferably saturated with a compound of gutta-percha and pitch or resin, which causes it to adhere firmly to the rope or cable. Silica or other similar hard powder is usually mixed with the gutta-percha and pitch, or similar composition, or a silicate, such as soapstone (silicate of magnesia).—Patent abandoned.

Patent abandoned.

3052 J. JEFFERYS, Upper Norwood. Preserving meat Dated October 6, 1868.

This refers to a patent, dated July 29, 1863 (No. 2384). The meat or other substance is frozen in flat boxes, say, a yard square, and 5in. to 10in. deep. The freezing surfaces are of sheet iron; the narrow sides are of deal board, for non-conduction. To preserve the flavour of the meat, and keep it from being bruised, it is surrounded by seasoned soup, made of all the available parts of the slaughtered animals not packed as meat. The blood is also utilized by being mixed with slaked lime and sulphate of lime for cement, for rendering the boxes soup-tight, and even airtight.—Patent completed.

2053 C. EXEMET. Kingston-upon-Hull. Extraction oils.

3053 C. ESKRETT, Kingston-upon-Hull. Extracting oils. Dated October 6, 1868.

A piece of iron, copper, or other material of the proper length and breadth is used, suitable to the size, shape, and length and breadth is used, suitable to the size, shape, and plain, corrugated, or chequered, as may be required. A projection is cast or otherwise fixed on the widest end of the plate, rising up nearly the thickness of the cake, rounding it on the top and back, and hollowing it at the bottom, towards the plate.—Patent abandoned.

3054 F. P. WARREN, Lee. Cooking apparatus. Dated October 7, 1868.

This consists in a novel combination and arrangement of boilers of peculiar form, with ovens and steam cooking or drying closets, the whole arranged so as to be heated by the products of combustion from one freplace, which is itself mainly formed by the boilers themselves, thus preventing the waste of heat and loss of time which occur in cases where other parts, such as cast-fron cheeks, are used to form the fireplace.—Patent completed.

to form the fireplace.—Patent completed.

3055 J. H. JOHNSON, Lincoln's Inn. Blankets for printing presses. (A communication). Dated October 7, 1863.

This consists in a novel textile fabric which will be found useful as a substitute for the ordinary blankets employed in printing presses. In manufacturing the improved fabric or blanket, to which the name of the. "Delegue blanket" is given, awarp of silk, spun, floss silk or cotton is used, worked by a satin twell mount, as is well understood by weavers; combined with this warp there is a woollen weft also operated as for satin fabrics. The fabric thus produced is to be coated on the satin warp side or face with a solution of caoutchouc, so that the fabric presents a perfectly smooth and pliable surface on one side. The other face remains without any finish whatever, presenting the appearance of a fabric composed entirely of wool.—Patent completed.

2056 D. MARSHALL, Leith, N. B. Packing for machinery.
Dated October 7, 1868.
This consists essentially in an improved packing to be used in making the joints of tubes in surface condensers water and steam-tight, and which may also be used for other similar purposes. The improved packing consists of a ring or tube of india-rubber or similar elastic material, having an annular groove or space formed at one end,

between the outer and inner periphery of the ring or tube, so as to form a kind of cupped ring, the edges of which will spread out under pressure and form a water and steam-tight joint.—Patent completed.

3057 W. Sievwright and G. Worral, Dundee, N.B. Pressure apparatus. Dated October 7, 1868.

This consists in the arrangement and construction of levers in which the pressure is produced by means of a weight, and rendered elastic by the introduction of a metal spring in contradistinction to levers in which the pressure is produced by means of a weight only, or by means of a compressed spring.—Patent abandoned.

means of a compressed spring.—Patent abandoned.

3058 J. H. Johnson, Lincoln's Inn. Spinning sotton.
(A communication). Dated October 7, 1863.

This relates, first, to the flyers for fly frames, or any frames where the flyers are removed for doffing, and consists in providing a curved tube or passage for the roving through the upper part of the flyer distinct from the socket by which the flyer is fitted on to the upper end of the spindle. Second, to centrifugal pressers for presser flyers, and the object is to afford facility for readily removing and replacing the presser arm when requisity for this purpose it is proposed to connect the arm of the flyer and the detachable presser by a spiral guide and worm situate either at the lower or upper portion of the flyer arm, so that when turning one way the presser tends to detach itself from the flyer, and when turning in the opposite direction it stops by the fact of the pressure arm itself coming in contact with the end of the flyer arm.—Patent completed.

3059 B. T. Monteith, Dinaid, France. Firebricks and

3059 R. T. Monteith, Dinaid, France. Firebricks and cement. Dated October 7, 1868.

This consists in composing the bricks and cement of a mixture of fireclay and oil still cake, a substance composed principally, if not entirely, of carbon.—Patent abandoned.

abandoned.

3060 E. T. Hughes, Chancery-lane. Generating electricity.
(A communication). Dated October 7, 1868.

This consists in the application of the substance called "galina" or "alquifore" (i.e., sulphuret of lead free from either silver or copper), to the production of electricity by heat, and one of the chief characteristics of the invention is the combination of this substance with iron to form a chemical pile, the said combination being effected by solder, preferably composed of alquifore mixed with about 10 per cent. of sulphuret of copper.—Patent completed.

2061 W. Rossiter. Accrington. Warping machines.

solder, preferably composed of alquilore mixed with about 10 per cent. of sulphuret of copper.—Patent completed.

3061 W. Rosster, Accrington. Warping machines. Dated October 7, 1868.

This consists, first, in the employment of wires stretched across the machine in contact with the levers, which are supported by the warp threads for the purpose of enabling the fluke to be continuously cleared away. Second, in the employment of vertical rods fixed a short distance from the frame sides for the ends or pivots of falling rods and rollers to work between, and in the wedges and levers for raising the front roller when required, and the slidding thats and hooks, and also in the levers worked by tappets on the stopping and setting on rods for holding up the falling rods after they have been raised. Third, in the form and application of the front end of the eccentric rod for working the oscillating shaft and pulling the spring handle out of its detent for causing the stoppage of the machine. Fourth, in the spring buffer in connection with the double catch wheel, and the arms or hinges at one or both ends of the helical spring for the purposes described. And, fifth, in an improved arrangement of mechanism for enabling the drum and warp beam to be turned in forward and backward directions with only one driving strap.—Patent completed.

driving strap.—Patent completed.

3062 J. WOOD and J. ARUNDALE, Hollingworth. Shuttles.

Dated October 7, 1868.

This consists in disposing the loose end of the tongue spring in a groove formed in the upper surface of the head or tumbler in the direction of its length, such groove either terminating in a hole bored through the remaining portion of the head or tumbler, or cut right through to the back. The extremity of the loose end of the spring is bent so as to enter the hole, and is thereby held in position, or, in the absence of the hole, a metallic strap or staple is affixed across the groove for the same purpose.—Patent abandoned.

W. E. NEWTON, Chancery-lane. Knitting machinery.

scross the groove for the same purpose.—Patent abandoned.

3063 W. E. Newton, Chancery-lane. Kaitting machinery. Dated October 7, 1868.

This relates to that class of knitting machinery wherein rectilinear reciprocating latch needles are arranged in a row, parallel to each other, and operated by means of a cam. The chief object is to arrange a bar in front of, and slightly above the plane of the needles, so that while the hooked ends of the needles pass beneath, the bar will operate as a latch holder, to prevent the latches (when thrown back) from falling on top of the hooked points of the needles, when the needles advance to receive the yarn from a yarn distributor. The bar is also arranged that it will serve as a support for the outer end of the yarn carrier, and so as to keep the yarn distributor always at a given height over the needles, as they advance to receive the yarn. Another object is to connect a latch holding bar with a movable work holder, so that when the hinged frame of the former is turned over out of working position, it will move the work holder a sufficient distance away from the jack bar to allow free access to and an inspection of the work upon the needles. Another object of the invention is to apply a fine wire in a groove made in the needle bed, just in rear of and parallel to the jacks, so that such wire shall serve as a means for shutting the latches, when the needles are drawn fully back, also as a means for opening the latches when the needles are moved forward to a working position, and also as a means for holding back the needles, and preventing them from being casually thrown forward, when it is desired to keep any number of needles out of working position.—Patent completed.

3064 J. WATSON, Newington-causeway. Wall papers.
Dated October 7, 1868, No. 3066. A block is then prepared with a raised surface, corresponding exactly with the raised patern to be produced. caving all the required lines and indentations thereon, or nails, or stude, or strips of metal are placed on the surfac

It is embossed or depressed in that position, and in this manner the raised portions from the face of the paper are formed. The carved block is dipped into a sieve of oil colour or other suitable adhesive substance not soluble in paste or water, and having adjusted the same immediately at the back of the pattern on the paper, by means of guide pins, or by other means, pressure is applied thereto by means of the ordinary "dolly" or in any other convenient manner.—Patent completed.

8065 J. Dupill, Whitechapel-road. Steres. Dated

October 7, 1868.

This relates to lace bottoms for sieves or screens. A moderately thin wire is placed above and below the longitudinal wires, and as each of the latter is inserted, the two former are twisted together, so that they are twisted or crossed between each wire, and beat or force up another longitudinal wire after each twist, so that as the top and bottom wires are twisted together between every two longitudinal wires, the latter are held perfectly firm and cannot get out of place.—Patent abandoned.

and cannot get out of place.—Patent abandoned.

3066 J. WATSON. Newington-causeway. Wall papers.
Dated October 7, 1869.
The ordinary roller or cylinder printing machine is employed, and the desired pattern printed upon the paper in water gold size. The paper is then conducted by rollers beneath a box or hopper, with a narrow aperture containing the gold, silver, or bronze powder, which distributes the same over the surface of the paper on which the pattern has been printed, immediately after which the paper passes over a revolving beater which strikes against the back of the paper, and throws off the superfluous metallic dust or powder which may be from time to time returned to the hopper and used over again. The paper may then pass between two "flatting" rollers, or may be dried and rolled at once.—Patent completed.

3067 W. ESTOR, Hampstead, and C. T. Pearcs, Maddox-

at once.—Patent completed.

3067 W. ESTOR, Hampstead, and C. T. PEARCE, Maddoxstreet, W. Disinfecting. Dated October 7, 1868.

This consists in a cup or vase of any convenient size, externally coated with finely divided charcoal (mixed with
adhesive substances, such as gum, starch, or gelatine), and
powdered or liquid sulphur which is dried in a hot room.

The interior of the cup is partly filled with chloride of
lime, from which sulphurous acid gas and chlorine are
liberated, filling the apartment, and thereby destroying all
infection, animalculæ, vegetable, and animal spores, and
leaving the atmosphere pure.—Patent completed.

3068 WESTLEY RICHARDS. Birminpham. Cartridox:

3068 WESTLEY RICHARDS, Birmingham. Cartridge Dated October 7, 1868.

3063 WESTLEY RICHARDS, Birmingham. Cartridge. Dated October 7, 1863.

A tube or capsule (by preference of brass) is employed, closed at one end, with the exception of a central hole of a size to allow the case for the fulminate to pass through. Or the case for the fulminate may be made in one piece with the tube or capsule. Within the capsule a lining cup is applied, formed so as not only to line the outer angle around the base of the capsule, but also to line the inner angle around the hat, cap, or percussion case, and this is done by forming the cup with a hollow projection raised up in its centre, so that when the cup is placed in the capsule, it covers over the hat, cap, or percussion case. The cup is pressed down into the capsule, until around the centre it rests solidly on its closed end or base. There is a perforation in the projection of the cup for the fire to pass from the fulminate to the charge. The upper end of the capsule where it receives the ball, the patentee frequently makes of a reduced diameter, and then the gum is made to correspond with the cartridge chamber larger in diameter than the bore.—Patent completed.

3069 R. H. BENTHAM, Bedford-row, W.O. Draughtman's

in diameter than the bore.—Patent completed.

3069 R. H. BENTHAM, Bedford-row, W.C. Draughtman's instrument. Dated October 7, 1868.

This consists in a flat ruler, similar to the well known rolling, perallel ruler, but instead of two wheels of the same size, one is made of greater diameter than the other, proportioned according to the requirements and made movable along the axie common to both wheels, and retained at any required distance from the other wheel. The nearer the wheels approach each other, the nearer will be the centre to which the lines will radiate.—Patent abandoned.

3070 H. JOSEPHI, Manchester. Watches and clocks. Dated

October 8, 1868.

The object is to prevent breakage when winding. A hollow barrel arbor is used, through or into which the winding square passes. The hollow arbor carries a ratchet wheel, provided with a cleck, and above this the winding square carries another ratchet wheel provided with a cleck. These ratchets are toothed in opposite or reverse directions.—Patent abandoned.

2021 G. Sprague Glocks and Markets and Markets

3071 G. Speight, Clerkenwell. Applying adhesive agents.

Dated October 8, 1868

Dated October 8, 1868.

In a framework, a trough slotted at bottom is mounted. In this trough a loose lining of muslin or other reticulated open meshed or porous flexible fabric is placed, which forms a sort of longitudinal bag or channel, and projects downward through the slot. The starch, gum, or other adhesive agent employed is introduced into the trough, and passes through the muslin or other fabric, and through the slot in the trough on to the material fed in continuous lengths or otherwise below the trough,—Patent abandand.

3072 J. CHAUDION, Brussels. Boring. Dated October 8,

1868
This relates to a previous patent, dated July 1, 1867
(No. 1916). It consists in the application of the system, apparatus, and tools described in the specification of the said letters patent to the boring or sinking of shafts and pits for mines and other purposes through aqueous strata, whereby the necessity of pumping the water out of such pits or shafts during the progress of the work is obviated. The apparatus employed is so arranged as to effect the complete isolation of the aqueous strata, thus enabling the work to be carried on through any depth of such strata more conveniently than heretofore.—Patent completed.

3074 J. MGRAY. Birkenhead. Working war turrets.

more conveniently than heretofore.—Patent completed.

3074 J. M'GRAY. Birkenhead. Working war turrets.
Dated October 8, 1868.

Revolving war turrets are worked by steam power machinery under the direct control of and operated by the person who is pointing the guns. According to one mode of working, this person is stationed in the turret and moves with it. According to another mode, the person who is directing the motion of the turret, and pointing the guns, is stationed at a look-out place at some distance from the turret and from the station. He operates an engine, which revolves the turret, and at the same time he points the guns by alming with a sight which is maintained in a direction at all times parallel with the guns in the turret.—Patent completed.

2075 E J. HUGHES, Manchester. Games. (A communication). Dated October 8, 1868.

This consists, first, in the adaptation to any ordinary billiard or bagatelle table, or to a table made for the purpose, of bells or gongs, combined with hoops and stalls for the purpose of playing with balls and cuce an improved game, which is called "croquet billiards." The stalls are held together at the top by a piece of wood, to which several gong bells are connected, and the remaining stalls are numbered as desired. Second, in the arrangement of a table mounted with pins or skittles in mittation of the American skittle alley, the pins on the table being struck by balls impelled by cucs. The table is formed with the proper gutters at each side and a proper track in the centre, and at the far end there is a trough or recess for the pins or skittles to fall into. Third, in an improved arrangement of folding table, to be used either for billiards, croquet billiards, skittles, or as an ordinary table. The portion of the table supported on legs or stands is the part intended for billiards, and to the ends of this part are hinged flaps.—Patent abandoned.

3077 F. AYCROURN, Southampton-street, Strand. Lead

hinged flaps.—Patent abandoned.

3077 F. AYCKBOUEN, Southampton-street, Strand. Lead pencils. Dated October 8, 1868.

The outer circumference of lead pencils is reduced within about \(\frac{1}{2}\) in in length of the end not intended to be cut, by filing or paring the same down to the extent of about 1-16th of an inch in depth. A coating of india-rubber, varnish, glue, or other cement, is then laid on the part that has been reduced, after which a suitable length of small bored india-rubber hose or tubing—vulcanized or not—is taken and drawn over the part which has been cemented, trimming off the edges with a wetted knife or scissors, when it forms an effective eraser.—Patent abandoned.

3078 E. PREVOST. 136, Euston-road. Controlling horses.

3078 E. PREVOST. 136, Euston-road. Controlling horses. Dated October 8, 1868.

This consists in the application of electricity, generated either by permanent magnets or by a galvanic battery, as found most convenient. In carrying out this invention, it is preferred to employ any suitable small and powerful magneto-electric machine, which may be situate convenient to the hand of the driver on a vehicle, as, for example, on or under the box seat. A wire or wires connect the magneto-electric machine or battery with the bit of the horse to be controlled, such wire or wires passing along or being enclosed or concealed within the reins.—

Patent abandoned.

as a sandoned.

3079 J. H. JOHNSON, Lincoln's-inn. Saw handles. (A communication). Dated October 8, 1868.

This consists of an ordinary saw blade, furnished with a slot, which, in form and size, corresponds to the form and size of a bolt, one end of which is provided with screw threads, to which a screw nut is fitted, which is placed in a recess made in the handle. The back end of the saw blade is fitted into a groove made in the front end of the handle. The part of the handle which is grasped by the hand of the operator is formed of wood, and is secured to the metal part by means of screws or rivets.

—Patent completed.

3080 W. SIMONS, Benfrew, N.B. Bricks. Dated Octob

1868.

This consists in making moulded bricks or blocks of a double dove-tailed form, the thinnest or narrowest part a double dove-tailed form, the thinnest or narrowest part of the brick or block being in the centre.—Patent abandoned.

3081 J. STEEL, Glasgow. Malt extract. Dated October 8,

1868.
This consists in arranging apparatus intended to contain the roasted malt in such a way that the worts may pass from the mash tun through it on their way to the boiler, and in constructing the extracting apparatus so that the worts may pass through the roasted malt in an upward direction, whilst the malt is kept stirred by revolving or other suitable agitators.—Patent completed.

2022 W. Reann. Kaichlaw. Looms. Dated Ootshar 8.

3082 W. BLAND, Keighley. Looms. Dated October 8,

1868.
This consists principally of a fluted iron roller, round and in contact with about three-quarters of the circumference of which the cloth is caused to pass. This roller is driven with a positive and constant motion by means of ratchets or otherwise, in the ordinary way, and has near one end a spurwheel gearing with a spur pinion on one end of a smaller iron roller placed above but not in contact with the fluted roller before named. The wheel and pinion are kept in gear by weighted levers bearing on the journals of the smaller iron roller.—Patent abandoned.

3083 G. DAVIES. Lincoln's Inn. Paper boats. (A com-

3083 G. DAVIES, Lincoln's Inn. Paper boats. (A communication.) Dated October 8, 1868.

This consists in attaching to the bottom and sides of such portions of the boat a series of longitudinal strips or pleces of paper or thin wood, or of prepared cloth of gradually decreasing width or length, and laid one over the other.—Patent abandoned.

the other.—Patont abandoned.

3084 J. Arnold, Sheffield. Steam botters. Dated October 8, 1868

This relates, first, to what are known as "upright" or vertical steam boilers. Second, to what are known as "Cornish" or horizontal flue boilers. It consists, principally, in inverting a hemispherical dish-shaped, conical, or other similarly shaped shallow auxiliary water space in the firebox, between the top of the latter and the upper side of the cross tube (or of the upper cross tubes, if more than one is used); and in connecting this auxiliary water space at the lower side to the cross tube by a short tube or ring, and at the upper side, with the water space above the top of the firebox, by means of two, four, or other convenient number of tubes, riveted, screwed, or otherwise fixed to the upper side of the auxiliary water space, and to the top of the firebox, so that there may be a free circulation of water between the water space, above the firebox, the auxiliary water space, and the cross tube—Fatent completed.

3085 R. Winder, Farningham. Boring holes. Detect

Patent completed.

3085 R. WINDER, Farningham. Boring holes. Dated October 8, 1868.

This consists of a frame resting upon wheels. Upon this frame is fixed a handle, to be worked by the attendant. The handle turns wheelwork or gearing attached to the frame, made of different diameters, to give power to the attendant. The wheelwork or gearing has a grooved or spiked pulley fixed to it, which is connected to other grooved or spiked pulleys by an endless chain strap, or rope. The pulleys being set in motion make the augurs or boring tools revolve, and dig out or bore the required holes. Weights are attached to the upper part of these augurs to press them into the ground. Long feathers or keys are fixed upon these augurs for nearly the length of

the round or square parts of the augurs-Patent abandoned

3086 J. DEWAR, Kircaldy, N.B. Food. Dated October 8.

3086 J. Dewar, Kircaldy, N.B. Food. Dated October 8, 1868.

The inventor takes, first, the entrails of recently slaughtered healthy animals, such as cattle, sheep, and pigs, and cleanses them, and then subjects them to careful desiccation, such as will expel the moisture, so far as practicable, without injuring the nutritive properties contained in the substances. For desiccation, he exposes the substances to a dry temperature of from 100 leg, to 212deg. Figh. Before desiccation it is advantageous to boil the entrails thoroughly, but this is not absolutely necessary. After the desiccation is complete, the substances are reduced to a meal or powder by any ordinary grinding apparatus. The entrails, cleansed as aforesaid, may be mineed, while raw (or boiled before or after being mineed) mixed with seeds, busks of grain, or other husks, or with bran, meal, or flour, and dried and used as food, in the form of cakes, a sufficient quantity of bran, meal, or flour is added to enable it to be kneaded and baked. Second, the inventor takes the entrails, cleansed as directed in the first method, and either with or without previous desiccation of the character therein described, and either before or after mineing them. He subjects them to the action of sulphurous acid, which he applies either in the form of aqueous solution of sulphurous acid of the ordinary commercial quality, say, of specific gravity 1-012, or in the form of a sulphito or bisulphite.—Patent completed.

3087 J. Dewar, Kircaldy, N.B. Making manure and decoloriting.

gravity 1012, or in the form of a sulphite or bisulphite.—Patent completed.

3037 J. Dewar, Kircaldy. N.B. Making manure and decolorizing. Dated October 8, 1868.

First, human or other animal excrements, the sewage of towns, or the blood of slaughtered animals, or vegetable matter or refuse, or other of the many animal and vegetable or other substances, suitable for manure, are mixed with soot or slag, and to this mixture a quantity of gas water is added. Second, soot or slag, or both of these substances, are mixed with gas water without mixing them further with the other substances before mentioned to such an extent as to thoroughly saturate the same. This combination forms a clean, convenient, and useful manure, which may be kept for any length of time. Third, blood and foecal and other animal, vegetable, and other matters suitable for manure, or any one or more of these substances, are mixed with the gas water, without soot or slag. This mixture affords a good manure, free from noxious effluvium, which will remain for a lone period of time in good preservation. According as the substances are more liquid or more solid, gas water is employed to the extent and in the manurer explained under the first head, omitting only the admixture of either soot or slag.—Patent completed.

3088 F. Gysel, Birmingham. Extending frames. Dated October 8, 1868.

This consists in the construction of a frame upon the

30-88 F. Gysel, Birmingham. Extending frames. Dated October 8, 1863.

This consists in the construction of a frame upon the principle of the apparatus known as "lazy tongs," which is mainly composed of a number of short pieces jointed together. To take a bedstead as an example, the expanding frame should be arranged with the series of jointed pieces to form the two ends of the bedstead, the ends being united by bars or rods, which support them and keep them parallel. The frame at one side or end is provided with guideways or slots at right angles, or nearly so, to the direction in which the said frame expands, and the end piece of each series of joints is provided with a stud or pin which works in the said guideway. Cords or bands should be also attached to the frame to support the mattress and other bedding.—Patent abandoned.

3080 T. HANCOCK, Drury-lane, W.C. Door knobs. Dated

3089 T. HANCOCK, Drury-lane, W.C. Door knobs. Dated

3089 T. HANCOCK, Drury-lane, W.C. Door knobs. Dated October 8, 1868.

This relates to improvements in door knobs or handles whereby they may be more securely attached to their spindles than heretofore, while greater simplicity in the fitting of the parts is also obtained. The square spindle on which the lock follower is mounted is screwed part of or throughout its length, and has a knob fixed at one end. In order to attach the knobs or handles to the door and spindle, a circular coilar is fixed over the lock aperture, through which and the door the screwed spindle is passed, and screw on the said collar or rose plate, so as to cover the collar. The knob is then screwed on at the opposite end of the spindle, tirst placing a rose plate loosely on the said knob as before, until a squared part of the knob abuts against the surface of the door, sufficient space being, however, left for the application of a back plate, which is provided with a transverse slot (slightly wider at one end, by preference) made at one side, by means of which it may be readily slid into position on the squared part of the knob.—Patent completed.

3090 M. P. Manfield, Northampton. Boot soles. Dated October 8, 1868.

This consists in attaching to the face of the sole or grain side of the leather a series of small, round, or other shaped

This consists in attaching to the face of the sole or grain side of the leather a series of small, round, or other shaped dises or studs of thick leather to take the tread and wear, and thus to protect the sole, and prevent its wearing down. These dises or studs of leather will add little to the weight of the boot or shoe, and will give it a quiet tread, while serving the purpose of the ordinary hob nails, which have the disadvantage of adding materially to the weight of the boot, and rendering it impossible to walk quietly upon bare floors or pavement in boots thus protected at the soles.—Patent completed.

protected at the soles.—Patent completed.

3091 W. E. NEWTON, Chancery-lane. Binnacle for iron ships. Dated October 8, 1863.

This consists in the construction of a binnacle for iron vessels, by means of which local attraction will be overcome without destroying the polarity of the needle. The invention consists in providing a receptacle around the compass in which the non conducting matter can be compressed to the requisite degree. The compass is pivoted within the ring, by means of the pivots, by which the ring is hung within a metallic cylinder. This cylinder is placed in an upright position in an outer larger metallic cylinder. The inner cylinder stands on legs, or is otherwise supported in the outer case, and the space between the two cylinders is filled with glass metallic oxides or other non-conducting material.—Patent abandoned, 2002 A. M-MILLAN, Mildmay Park. Button. Dated

other non-conducting material.—Parent abundanced.
2022 A. M-MILLAN, Mildmay Park. Buttons. Dated
October 8, 1868.

Metal buttons, such as are usually applied to trousers,
are stamped as heretofore from sheet metal, but in place
of forming four perforations in the centre of the button, a
single central perforation is formed. To attach such a
button to the garment, a stud or shank is employed, con-

sisting of a stem with a head at one end. The stud or shank is inserted through the fabric, so that its head remains at the back. The button is then placed upon the stem, which passes through the perforation as far as a shoulder, which, is preferred to form upon the stem, and then, by a suitable nipping tool or by other means, the end of the stem is elenched or expanded over the button, which thus becomes held.—Pattent completed.

the button, which thus becomes held.—Patent completed. 3094 II. A. BONNEVILLE, Parls. Pumps. (A communication). Dated vectober 9, 1868.

This consists, first, in a pump called orthodynamical, constructed in accordance with the principles of suction in the lifting pumps, usually known as chain pumps. Second, in the transformation of the chain pumps into portable exhausting pumps, by adapting them to a frame which may be readily carried, and working them either in a vertical or an inclined position. Third, the disposition of the pump, so that it may be able to lift water to any height which a unap barrel of a limited length should. Fourth, the construction of a chain which has the wedge gearing into the V-shaped throttle of a pulley or wheel. Fifth, the construction with any sort of chair, strap, rope, or cable of chains, straps, cables, or ropes, which permit the actuating of pulleys or wheels without sliding.—Patent completed. completed.

completed.

3095 J. Peel, J. F. Broadbent, and J.M. Baines, Bradford. Piclers. Dated October 9, 1868.

In the manufacture of the improved picker the following proportions of metals are used:—Copper, one-half; blook tin, one-fourth; and zinc. one-fourth. These are melted together and east in moulds of the required form. The picker is also provided with a tube or bush of glass, earthenware, or other similar material, through which the spindle of the shuttle box is passed. The picking strap is attached to a cross pin at the upper part of the picker, which pin is screwed or chased at one end, and, by the use of a nut, serves also for the purpose of securely holding the glass tube, above-mentioned, firmly in position.—Patent abandoned.

3096 W. JARONS, New Brighton. Poison labels. Dated

3096 W. Janons, New Brighton. Poison labels. Dated October 9, 1808.

A piece of flexible cardboard is taken and passed around the neck of the bottle. When in that position the sides are fastened by a stud or otherwise, and a conical cardboard projection or abield is then left, which very much resembles an ordinary shade fitted to a careel or other lamp.—Patent abandoned.

other lamp.—Patent abandoned.

3097 T. W. Dyer, Barnsbury-road. Anti-chimney smoker-Dated October 9, 1868.

The anti-chimney smoker consists of a fan or coil made of any metal, with a cap on the top, also made of any metal, working on a vertical spindle, attached to a cross bar, secured to the brickwork on either side by stay nails, with holes at the end of the said stay nails, to fix the cross bar in with screws.—Patent abandoned.

3098 H. DEACON, Appleton. Sulphuric acid. Dated

3008 H. Diacon, Appleton. Sulphuric acid. Dated October 9, 1898.

This consists in effecting the production of sulphuric acid by causing, first, a mixture of chlorine and sulphurous acid in a gaseous form together with the vapour of water, either at a low or at an elevated temperature, to commingle. Second, by causing chlorine and sulphuric acid, in a gaseous form, to pass into the lower portion of a tower or series of towers, filled with materials not acted upon by the elements employed, or by the products resulting, and allowing the gases to come in contact with a descending stream of water, either at a low or at an elevated temperature. Third, by causing chlorine in the gaseous form together with the vapour of water, to act either upon sulphur or upon metallic sulphurots, or mixtures of the same.—Patent abandoned.

3099 L. HANNART, N. A. AUBERTIN, and W. J. CUNNINGHAM, Oxford-street. Door plates, &c. Dated Octothin sheet of metal is taken, and the letters entirely

A thin sheet of metal is taken, and the letters entirely cut out by means of a saw or other cutting instrument, the plate being moved on a table in the direction of the shape of the letters, similar to fret work in wood carving. The plate so cut out is then fixed to a plain piece of metal or other material, either painted or coloured on one side, or a coloured substance may be placed between the two plates, or the letters may be filled with coloured wax, as commonly practised.—Patent abandoned.

commonly practised.—Patent abandoned.

3100 E. Evans, Neath, Wales. Propelling boats. Dated October 9, 1868.

This consists in causing the propellers of boats to act so as to prevent the washing of the banks of canals or other narrow water courses. It is proposed to effect this by forming the boat in two parts, leaving a space of two or three feet, more or less, between them and connected together by a false or auxiliary bottom of sheet metal or other suitable material. Between the two boats, one or more propellers are adjusted so as to be actuated by toothed gearing, set in motion by a steam engine or other prime mover. The propellers act upon the water passing between the two boats, and over the false bottom thereof, instead of acting upon the body of the water in the canal, as heretoforo.—Patent completed.

310 H. A. Achereau, Paris. Obtaining heat and light.

water in the canal, as heretoforo.—Patent completed, 3101 H. A. ACHEREAU, Paris. Obtaining heat and light. Dated October 9, 1868.

This consists in the application of flames produced by the combustion, atornear the point required, of solid, liquid, or gaseous inflammable matters in combination with suitable aids to combustion, by injecting the combustible matters under pressure, previously heated into the various liquid, liquicalable, pulverulent or viscous matters contained in suitable receivers, in order to heat or act chemically or mechanically on the said matters. The invention further consists in the application of the above mentioned flames for the manufacture of iron and steel, and to chemical operations for the production of light and vapours, and for treating gases and vapours.—Patent completed.

3103 W. J. CURTIS, Holloway. Sewing machines. Dated

3103 W. J. Curtis, Holloway. Seeing machines. Dated October 9, 1886.
This object is to produce a secure and fast stitch, with only one thread. To this end, a needle and thread are employed in the manner usually adopted in sewing machines, but underneath the work plate, a double-acting hook is mounted, and is rotated alternately in opposite directions. When the needle carrying the thread passes down through the work, the hook is rotated, say, to the lett, so as to cause its point to pass through the loop in the thread, and by continuing its rotation, say, for one complete turn, the thread is twisted, and a loop is formed through which the needle on its second descent passes and liberates the

thread from the hook, which will then be vibrated or turned in the opposite direction.—Patentabandoned.

surned in the opposite direction.—Patent abandoned.

3104 S. Traghheim, Swinton-street, W.C. Dissolving substances. Dated October 9, 1868.

This consists in a perforated disc supported upon feet or upon a rim. Between the under part of the disc and the bottom of the interior of the vessel to be heated, fans fitted to a shaft or shafts, revolving parallel with the plane of the perforated disc, are placed. The substance and liquids to be treated are to be placed upon the perforated disc, and the rotation of the fans will assist in keeping up a circulation of water.—Patent abandoned.

circulation of water.—Patent abandoned.

3105 J. C. Morgan, H. Macaulax, and F. W. Waide, Rotherham. Cast-iron cidens. Dated October 9, 1868.
This consists in custing cisterns and their lids with rounded or curved corners or edges instead of with angular corners or edges, as heretofore. The cisterns are thus enabled to be cast much lighter than heretofore, without any danger of their cracking. It is preferred that the corners should be rounded off to a curve of a radius of 1 in., but this may be greatly varied.—Patent completed.

of 1 in., but this may be greatly varied.—Patent completed.

3106 W. T. Read, Old Broad-street, E.C. Treating bottles.
Dated October 9, 1863.

This consists in the application of a preventative or preservative solution or fluid in the form of a fine spray diffused throughout the interior and upon the inside surface of the bottle. The atmosphere contained within the bottle may thus also be charged with the sulphurous acid or other gas evolved from the said solution or fluid. This is effected immediately before the bottle is filled with the beer or other liquid.—Patent completed.

3107 B. WALKER and T. F. A. PLAUK, Leeds. Reducing bull.log. Dated October 9, 1868.

A strong metal pan is employed, the internal form of which is, by preference, an inverted truncated cone. It is open at the bottom, and the sides are chequered or fluted. In or near the centre of the pan is mounted a conical shaped pestle, which is also an inverted truncated cone, but its incline is less than that of the pan; it may also be checkered or fluted. This pestle is, by preference, fixed to the piston rod of an ordinary steam hammer, which piston rod is firmly guided. The pestle may be moved up and down by an ordinary eccentric motion, or it may be coupled direct to the piston of an ordinary steam engine.—Patent completed.

3108 J. Griffiths, Chesterfield. Iron or steel piles.

it may be coupled direct to the piston of an ordinary steam engine.—Patent completed.

3108 J. Griffiths, Chesterfield. Iron or steel piles. Dated October 9, 1868.

The exterior of the pile is made of four bars or plates; the top and bottom bars overlang or embrace the side bars and hold them in their places. The inner faces of the overhanging edges of the top and bottom bars are inclined, and the edges of the side bars are also inclined so as to fit against the inclined faces of the top and bottom bars, and form therewith what is commonly known as a scarf joint. The interior of the box or case of the pile thus formed is filled with bars or scrap, the said bars or scrap being arranged to suit the particular manufacture to which the pile is to be applied.—Patent abandoned.

3109 D. and G. HALLAS and L. J. WOODHOUSE. Regulating gas burners. Dated October 9, 1868.

A tap or cock of peculiar construction is used. On the face of the centre part, within which the cock turns, an index marked at given intervals is placed, in order to denote that when the handle of the cock is severally opposite to them, gas for the various numbers of lights which they denote is being passed through. The rotating part of the cock itself is made hollow, and pierced in its circumference with holes of varying size, so regulated that each is capable of supplying a given number of lights, and no more, and the gas is emitted into the supply pipe through an eblong port or slot in the cock which is opposite the holes.—Patent abandoned.

310 G. P. Grant, Wandsworth. Cast bushes. Dated

through an oblong port or slot in the cock which is opposite the holes.—Patent abandoned.

3110 G. P. Grant, Wandsworth. Cast bushes. Dated October 9, 1868.

This consists in forming one or more small V-shaped projections or rings on the under side of the flange of the bung bush and extending it. The projections are to be pressed into corresponding grooves cut in the wood at the time the outside of the stave is being faced to receive the flange of the bung bush. The bush is liked in the cask or similar vessel by expanding the whole or parts only of the circumference of the inner edge of the ferrule of the bush into the wood of the stave, so that a reverse como or dovetail shall be formed in order to prevent leakage, and to secure the bush firmly in the stave. The inner edge of the bush may be corrugated to facilitate its expansion without rupture, or it may be left plain. V-shaped grooves are also formed on the outside of the conical part of the bush at right angles to and intersecting each other, so as to produce a number of points, which are pressed into the sides of the bung hole in order to retain the bush in the stave.—Patent completed.

# APPLICATIONS FOR LETTERS PATENT

Dated April 12, 1869.

Dated April 12, 1869.

1115 W. Crombleholme, Manchester. Improvements in apparatus for registering the number of persons entering into, and going out of, public vehicles and buildings, or places of amusement, or over bridges.

1116 E. D. Temple, King William-street, City. Improvements in railway signals.

1117 J. Kirk, Woolwich, Kent. Improvements in cabs, carriages, or other vehicles.

1118 S. F. Shore, Balance-hill, Uttoxeter, Staffordshire. Improvements in apparatus for propelling railway carriages, trucks, and other vehicles.

1119 J. Easton, Taunton. Somersetshire. Improvements in the construction of drop drills.

1120 W. R. Lake, Southampton-buildings, Chancerylane. An improved railway.

1121 E. Beanes, Cordwalles, near Maidenhead, Berks. Improvements in brewing.

1122 A. d'Azambaia. Joinville-le-Pont, France. Improvements in the manufacture of felted fabrics.

Dated April 13, 1869.

1123 H. Browne, Liverpool. Improvements in veloci-

1194 C. D. Abel. Southampton-buildings, Chancery-lane. n improved machine or apparatus for aerial navigation. 1125 S. Holman, Laurence Pountney-lane, City. Im-

provements in velocipedes, parts of which improvements are also applicable to lifts, cranes, and other revolving

provements in velocity.

provements in velocity.

1126 T. F. Cashin, Gresham House, Old Broad-street, ty. Improvements in indicators in connection with itches or points on railways.

1127 T. B. Burns, Camelford, Cornwall. Improvements in the construction of cases to be employed with breechloading frearms to render them available for use with ordinary loose ammunition.

1128 W. Brock, Glasgow. Improvements in, and connected with, slide valves.

1129 J. Boberts, Birmingham. Improvements in draw plates or fire hasteners.

1180 C. Turner, Southampton. Improvements in cowls for chimneys and shafts.

1131 B. J. B. Mills, Southampton-buildings, Middlesex. Improvements in the manufacture of boots and shoes, and in machinery employed therein.

1182 E. E. and C. Marshall, Cheltenham, Gloucestershire. Improvements in apparatus for distributing fumigating matter, in order to destroy insects and files on plants.

plants.

1133 W. Gillespie, Coupland-terrace, Plumstead, Kent. Improvements in furnace bars, and in the mode of arranging and using them so as to consume smoke and economize fuel.

1134 W. E. Newton, Chancery-lane. Improvements in joints for railroad rails.

1135 A. V. Newton, Chancery-lane. An improved construction of fan blower.

1136 J. H. Johnson, Lincoln's Inn-fields. Improvements in machinery or apparatus for making compound telegraph wire or conductors.

1137 F. Erskine, Manchester. Improvements in firebars and arrangements for economizing fuel and constraints.

bars and arrangements for economizing fuel and con-suming smoke, applicable to steam boiler and other fur-

1138 J. H. Johnson, Lincoln's Inn-fields. A dental

naces.

1188 J. H. Johnson, Lincoln's Inn-fields. A dental wash.

1199 M. Samuelson, County-buildings, Kingston-upon-Hull, and C. Eskrett, Kingston-upon-Hull. An improved combined metallic envelope and filling plate to be used in expressing oil or fatty matters from seeds or other oil or fat yielding substances, and especially in the manufacture of oil cake.

1140 J. Leechman, Angleses. Villas, Hammersmith, Improvements in steam engines.

Dated April 14, 1869.

1141 E. Dowling, St. John's Wood, Middlesex. Improvements in planoforte actions.

1142 J. Chandler, Cottage-grove, Mile End-road, Middlesex. Improvements in planoforte actions.

1142 J. Chandler, Cottage-grove, Mile End-road, Middlesex. Improvements in apparatus for drawing and preventing waste of water from pipes, mains, cleterns, or other sources used for domestic or other purposes.

1143 P. A. Blake, Aberdeen Park, Highbury, Middlesex. An improved safety explosive compound, and the apparatus connected with its use.

1144 A. H. Benton, Great Queen-street, Westminster. Improvements in the mode of jointing pipes and tubes, and in the packing employed therefor.

1145 W. H. and T. Hacking, and J. Chambers, Bury, Lancashire. Improvements in machinery for sizeing and preparing warps for weaving, also for improvements in looms for weaving, and for improvements in machinery for folding or plaiting woven fabrics.

1146 C. Keighley, Burnley, Lancashire. Improvements in velocipedes.

1147 J. M'Lauchlan, Clyde Pottery Company, Greencek, Benfrewshire. Improvements in the manufacture of retorts for reburning animal charcoal, for making gas, and for other like uses.

1148 T. Akinson, Bell-street, Preston, and R. Smith, Victoria Foundry, Bold-street, Preston. Improvements in the construction of indicators for indicating the distance travelled by carts, waggons, carriages, or vehicles of every description.

1149 J. Whiley and S. J. Peet, Leeds. Improvements in machinery for producing moulds and cores to be used in casting metals.

1150 B. W. Farey, Bermondsey, Surrey.

a team engines.

1161 W. Wright, Mostyn, Flintshire. Improvements in reating ores to obtain copper and other metals there-

treating ores to obtain copper and other mounts from.

1152 J. H. Johnson, Lincoln's Inn-fields. Improvements in apparatus for burning liquid hydrocarbons applicable to the generation of steam and other heating purposes.

1163 J. G. Jennings, Palace Wharf, Stangate, Lambeth. Improvements in building blocks, and in the construction of buildings, and in appliances necessary to warming and draining the same.

1154 T. White, Birmingham. Improvements in nutorackers and lobster crackers, and in apparatus to be used with nutcrackers.

1155 W. Gradwell, Manchester. Improvements in steam boilers.

1155 W. Gradwell, Manchester. Improvements in steam boilers.
1156 C. T. Swanston, Holly House, Twickenham, Middlesex. Enabling railway trucks and carriages to be drawn by horses or traction engines on common roads, so as to prevent the necessity of loading and unloading at railway stations.

1157 A. M. Clark, Chancery-lane. Improvements in the manufacture of india-rubber nipples for feeding bottles, and in the means employed therefor.

1158 C. E. Brooman, Fleet-street, City, patent agent. Improvements in apparatus for burning liquid hydrocarbons. (A communication).

cation).

Dated April 15, 1869.

1160 H. J. Worssam, Wenlock-road, City-road, Middlesex. Improvements in machinery for lifting casks, boxes, bales, or packages, from one floor to another.

1161 G. Black, Spittlegate, near Grantham, Lincolnshire, Improvements in agricultural drills for sowing grain and seeds with or without manure, and also for distributing

seeds with or without manure, and also for distributing manure.

1162 W. H. Buck, Stretford, near Manchester. Improvements in velocipedes.

1163 E. Cooper, Laurence Pountney-lane, City. Improvements in the manufacture of waterproof coats, and other waterproof articles of dress worn externally.

1164 R. Heyworth, Manchester. Improvements in water-closets, and in self-acting apparatus connected therewith, part of which improvements is also applicable to urinals.

1165 A. W. C. Williams, Southampton-buildings, Chancery-lane. Improvements in bottles and jars for preserving fruit and other substances, and in stoppers for the

anne.

1166 F. J. Bramwell, Great George-street, Westminster. Improvements in steam engines and furnaces.

1167 J. Vivian, Falmouth, Cornwall. Improvements in engines, pumps, and machinery to be used in mining, partly applicable to other purposes.

1168 A. M. Clark, Chancery-lane. Improvements in compasses, and pen and pencil cases or holders.

1169 J. M. Johnson, Lincoln's Inn-fields. Improvements in motive power engines and steam generators.

1170 W. J. Cowlman and A. Doe, New Windsor, Berks. Securing greater accommodation and facility in the use of school desics, tables, and seats, which is also applicable for other purposes.

of school desks, tables, and seats, which is also applicable for other purposes.

1171 A. K. Rider, New York, U.S.A. Improvements in valves and valve gear for steam engines, and in the means for operating and adjusting the same.

Dated April 16, 1869.

1172 F. Mulliner, Northampton. Improvements in the construction of wheeled carriages.

1173 L. Eggert and O. E. Pohl, Liverpool. A new mode of constructing vessels of war with due regard to their protection from shot and shell.

1174 F. F. Whitchurst, Cambridge Cottage, Richmondroad, Putney, Surrey. Improvements in apparatus and machinery for mashing grain and obtaining products therefrom.

nerefrom.

1175 B. Legg, Owen's-row, Clerkenwell, Middlesex.

urther improvements in machinery for spinning or

therefrom.

1175 B. Legg, Owen's-row, Clerkenwell, Middlesex.
Further improvements in machinery for spinning or
twisting and winding tobacco.

1176 W. H. Thick, Kentish Town, Middlesex. Improvements in fret cutting or sawing machines.

1177 S. Harrison, Liverpool. Improvements in apparatus, and arrangement of same for ventilating, gaining
access to, and flushing, street and other sewers and drains,
also in purifying the noxious gases arising therefrom,
parts of which improvements consist in gully stench traps.

1178 G. T. Bousfield, Loughborough Fark, Brixton.
Improvements in the manufacture of heavy hydrocarbon
oils, and in apparatus used therein.

1179 A. F. Craig, Paisley, Renfrewshire. Improvements in apparatus for cutting or dividing pasteboard or
other sheets to form cards and the like.

1180 J. H. Johnson, Lincoln's Inn-fields. Improvements
in firearms, and in elevation sights for the same.

1181 W. E. Newton, Chancery-lane. An improved
sefety attachment to be adapted to burners for burning
explosive gases for illuminating and other purposes.

1182 J. Ives, Thame, Oxfordshire. An improved construction of velocipede.

Dated April 17, 1869.

1183 P. Bogler and H. Kayser, Vienna, Austria. An
improved lift for raising and lowering merchandize and
weights of all descriptions.

1184 E. T. Hughes, Chancery-lane. Improvements in

weights of all descriptions.

1184 E. T. Hughes, Chancery-lane. Improvements in rifled firearms and ordnance, and in ammunition for the

ame.

1185 P. Bogler and H. Kayser, Vienna, Austria. Improvements in means and apparatus for regulating or controlling the delivery of tickets at railway stations and other similar places, part of which invention is applicable to telegraphic purposes.

1186 F. J. Knewstub, St. James-street, Middlesex. Improvements in the process of printing.

1187 H. W. Dee, Sherwood-street, Golden-square, Middlesex. Improvements in making bottles, jars, and similar articles, air and liquid tight.

1188 T. Amies, Peterborough, Northamptonshire. Improvements in apparatus for heating water for warming greenhouses and other buildings, and for other purposes.

1189 J. Willats, Stamford-road, Kingsland, Middlesex, and A. J. Martin, Stratford, Essex. A new mode of advertising.

and A. J. Martin, Stratford, Essex. A new moue or advertising.
1190 T. Page, Adelphi, Middlesex. Improvements applicable to rail, tramway, and road locomotives. Dated April 19, 1869.
1191 A. Smith, Mauchline, Ayrshire. Improvements in ornamenting hats, caps, bonnets, and other coverings for the human head.
1192 R. Chapman, Berwick-place, Bellevue, Shrewsbury. Improvements in railway fish plates, and the mode of fix-ing the same.

ing the same.

1193 J. Horsley, Cheltenham, Gloucestershire, provements in the manufacture of blasting pow

1193 J. Horsley, Cheltenham, Gloucestershire. Improvements in the manufacture of blasting powder or explosive compounds.

1194 H. A. Bonneville, Sackville-street, Piccadilly. An improved apparatus to manufacture the rims of hats.

1195 P. Bourchani, Paris. Improvements in the construction of hydraulic barometical apparatus for raising beer, wine, and other liquids.

1196 W. H. Smith, jun., Salisbury-street, Strand, W.C. Improvements in lavatories, and in taps, valves, and fittings to be used in connection therewith, for regulating the admission and discharge of water, which taps and valves are also applicable to other purposes.

1197 H. Aitken, Falkirk, Stirling. Improvements in treating iron ores or iron stones.

1198 J. E. Ward, Bredbury, Chester. Improvements in nats or coverings for the head, and in the construction or manufacture of the same.

1199 A. V. Newton, Chancery-lane. Improvements in friction matches, and in match boxes or holders for containing the same.

1200 H. V. D. Scott, Ealing, Middlesex. Improvements in pottery ovens or kilns and glass and other furnaces.

1201 S. Shaw, Southampton-buildings, Chancery-lane. An improved feed-water apparatus, chiefly designed for supplying and maintaining a proper water level in steam bollers.

PROVISIONAL PROTECTION FOR SIX MONTHS Has been granted upon Specifications bearing the following numbers:—

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in p. stage stamps, for sums above that amount a Post Office Muney Order should be sent, psyable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.O., to whom all communications upon the subject should be addressed.

THE

# MECHANICS' MAGAZINE.

LONDON: FRIDAY, APRIL 30, 1869.

# BOURNE'S AUXILIARY PROPELLER.

THE pages of the Mechanics' Magazine and the records of the Patent Office alike testify to the many attempts that have been made to obtain an auxiliary propeller for assisting sailing vessels out of calms. The importance of such an application has ever been felt, but the want has never been practically satisfied. Trials of various schemes there certainly have been, but a close inquiry has not enabled us to discover that any of the plans so tried have ever outlived the experimental stage. Paddles and screws have been pressed into the service to supply the deficiency, but these appliances have ever carried with them insuperable objections. Either they have proved too cumbrous to be capable of being readily applied and removed, or else they had an insufficient grip of the water to propel a heavy ship efficiently without most of the power being lost in slip. In other cases, the form of the ship has been modified below the water for the reception of propellers. Her efficiency under sail alone has thus been impaired, and part of the hold has been occupied with machinery which required perforations to be made in the hull, just as in the case of full-powered steam ships. Seeing all this, and being fully alive to the importance of applying an auxiliary power to sailing vessels, Mr. John Bourne—who needs no further introduction at our hands—set himself to work to solve the problem. That he has effectually succeeded in so doing we shall That he make clear to all before we have concluded our present article.

The matter was brought directly under Mr. Bourne's notice by Messrs. Currie and Co., the owners of the Castle Line of fine sailing vessels trading between London and Calcutta. Considerable loss of time being frequently experienced on this route, by reason of dead calms, Messrs. Currie applied to Mr. Bourne to help them out of their diffi-This he did by devising an exceed-simple and yet thoroughly effective apparatus upon the principle of the vertical oar, moved with a sculling motion. The oar, which is hung upon a folding or lifting bracket above the water line, is moved to and from the side by a crank in connection with the steam gear. The feathering is effected by means of a short tiller, which is also moved by a crank, having the same throw, but set at a different angle from that of the crank which moves the oar to and from the side. The action is perfectly smooth and regular, and the propelling efficacy of the oar is equal at all parts of its throw—the diminution in the velocity of lateral movement to-wards the end of the throw being exactly compensated by the increase of the pitch, so that the amount of slip at all parts of the stroke is uniform, and no inconsistent motions are imparted to the water. At the end of the throw the pitch becomes infinite, or, in other words, the face of the blade stands in a line parallel with the keel. But at this point the lateral motion is infinitely slow; the oar, in fact, comes to a state of rest, so that neither at this nor any other point is the retrogressive slip other than a constant quantity. The amount of slip, moreover, is small, and the engine power is beneficially utilized in the propulsion of the vessel. In a screw, the propelling area is represented by the area of the circle in which the screw rotates, and in this propeller the propelling area is represented by the area of the arc in which the oar vibrates. As this area may pumping the ship, in extinguishing fire, and amount of travel they have, precludes the be made of any desirable magnitude, merely in furnishing fresh water for the crew, will possibility of noise or jarring. The pump,

by increasing the length of the oar and the length of its throw, it follows that sufficient propelling area, even for the largest ships, can be obtained by this expedient without any difficulty. The mechanism for moving and feathering the oar stands on the deck, and is worked in connection with the steam winches, so that the additional machinery for propelling in the case of vessels having steam winches is merely the oar itself and its connections.

Such, in brief, is the apparatus which Mr. Bourne has fitted to one of Messrs. Currie's ships, the "Warwick Castle," and the efficiency of which we saw demonstrated last Tuesday afternoon. The "Warwick Castle" is a fine vessel, of 1,160 tons burthen, and is now lying in the East India Dock, whence she will sail to-morrow (Saturday) for Calcutta. On the present occasion, three short runs were made in the small space that could be cleared in so crowded a dock. The apparatus answered admirably, and the ship was brought back to her moorings in each case by the propeller. In the third run, the pitch was slightly altered, and made a little finer, which had a visible and marked effect upon the speed, showing a decided increase in it. Of course, these trials were made over so short a run, that anything like the exact rate of speed could not be correctly ascer-tained. But the ship will be put through further experiments after leaving the dock, the results of which we hope to place before our readers next week, together with an illustrated description of the apparatus itself. The trials of last Tuesday, however, go far to show that the apparatus will move a ship of large tonnage from a state of rest, and, this accomplished, her onward motion follows as a matter of course. Mr. Bourne expects a speed of about two knots an hour to be got out of the vessel with this propeller; we think he estimates it rather low, and should not be surprised if the trials in open water gave a better result than this. But even if it does not, we shall be well satisfied with the above rate of speed, which will be a great boon to a sailing ship in a dead calm.

It will be seen that by the apparatus under

notice all the evils of auxiliary methods embodying the paddle or the screw are avoided. and the small amount of steam power required to work the cargo winches in harbour is rendered available for the effectual propul-sion of the vessel in calms, merely by letting down a sculling oar vertically on each side of the ship; or one oar only on one side may be employed, as in the case of the "Warwick Castle." In the use of these vertical oars, moved with a sculling motion, there is nothing absolutely new, as the galleys of the ancients were propelled in this manner; and Mr. Bourne does not pretend that these oars are more efficient than either paddles or screws encountering an equal area of water. But in the case of a paddle or screw having an equal propelling area, those instruments would become so large and cumbrous as to be really unmanageable as auxiliary propellers. On the other hand, in the case of a sculling oar, no such impediment occurs, and it may be both dropped into the water and lifted out of it with the greatest facility.

The whole apparatus and gearing weighs under 30cwt., and it is readily taken to pieces and stowed away within a very small space. Then, as to cost, the extra expense is not worth consideration in view of the advantages obtained. The cost of a steam winch is about £150, and for another £150 the auxiliary propeller can be added, and only requires the aid of the steam winch at the very time when it is unemployed. The use of an efficient auxiliary apparatus to propel vessels in calms will almost always save several days on an eastern voyage, and sometimes several weeks; while the application of steam, which may also be made useful in

add to the safety of the voyage, while imparting a uniformity in its duration such as could not otherwise be attained. These considerations, at all times important, have attracted renewed attention from the expected opening of the Suez Canal at no distant date, when it will be found advantageous to sailing ships to be able to propel themselves through the canal, without being put to the expense of employing tugs. Ships of 1,000 to 1,500 tons may be propelled by Mr. Bourne's apparatus, at a speed of about two knots an hour, with an indicated power of eight or ten horses, and with a consumption of about 30lb. of coal during each hour that or about 3010, or coal during each nour that the propeller is in use; so that, look at it which way we will, we can only see reason to congratulate Mr. Bourne upon the happy application of the principle of the vertical sculling oar, and shipowners upon now being placed within their reach the means of shortening the passage of vessels under the in-fluence of that bele noir of seamen and shipowners-a dead calm.

# ATMOSPHERIC MONEY MAKING.

IN the very long list of "things not generally known," may be placed the fact that every coin of British mintage, circulating in these realms, owes its ornamentation to the pressure of the atmosphere. The medals which decorate the breasts of so many of our gallant soldiers and sailors have derived their impressions from the same source, and, in point of fact, therefore, the atmosphere is our chief coiner and chief medallist. This potent official does his duty to perfection, and his services—unlike those of other servants of the State—are rendered gratuitously. Let us endeavour to explain the mode by which atmospheric money making is carried on at the Mint, and how it is that the air which sustains our lives is made to stamp the coins carried in our pockets. The main feature in the process of atmospheric coining is the air-pump, for, in order to use the atmosphere effectually as a mechanical power, a vacuum must somehow be first created. The air-pump used for the purpose of coining at Tower Hill is of peculiar construction, and was originally invented and introduced into the Mint by Mr. Newton, an officer of that establishment, and president of the Foremen Engineers' Association. It consists of a castiron cylinder, closely resembling in exterior appearance that of an ordinary land steam engine, but of very different internal construction. The piston is a solid body surrounded by elastic metallic bands, which are pressed outwards by springs, so as to fit the cylinder in an airtight manner. The base of the cylinder is a hollow casting of iron, and its cover is of the same material These casings. or jackets, as they may be termed, are in reality the receptacles for a great number of small inlet and outlet valves. The upper casing contains no less than sixty-four valves, all of which are of the simplest form and, indeed, are nothing more than narrow strips of sawplate, 3in. in length, and each attached by a screw at one end. Thirty-two of the spring valves open outwardly to the atmosphere, and thirty-two inwardly to the exhaust pipe. The lower casing is similarly fitted. diameter of the air-pump cylinder is 42in., and the length of stroke of the piston is 36in. A vertical rod dependent from the beam of a steam engine—which also pumps water from a deep well for the supply of the Mint—works the piston. Communications by covered easings outside the cylinder are made between the upper and lower delivery and exhaust pipes.

By this mode of construction, it will be seen that Mr. Newton's air-pump is made double-acting, for it both exhaust and delivers air at every upward and downward stroke. The great number of valves, and the small

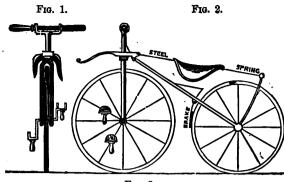

in fact, is absolutely silent in its operation, and it works with the greatest smoothness. It has been in action for several years, and has been the medium for coining upwards of one hundred millions of sovereigns, besides 3,000 tons of bronze coin. Its original cost, with 200ft. or 300ft. of 12in. cast-iron connecting pipes, and gauges, was £350, and it has never once been out of order. As compared with the expense of the system of coining practised before its introduction to the Mint, the atmospheric coiner of Mr. Newton saves the country not less than £200 per annum. That gentleman is not, however, a military officer, and, therefore, perhaps, he has never been rewarded by the Government for his valuable invention.

It has been said that the exhaust pipe was about 200ft. in length. That, indeed, is the distance between the air-pump and the coining presses, and the communication is made over the roof of the coining department. At the right point for the purpose, the exhaust pipe dips downward, and is united to a vacuum chamber. This is a long cylindrical vessel of cast iron, some 30in. in diameter, and placed along the floor in a line parallel to that of the eight coining presses. When the air-pump is in action, this chamber is exhausted to an extent which may be regulated to infinite pricate by a relief valve and lated to infinite nicety by a relief valve and barometrical gauge. That extent is varied with the size of the medals or coins to be atmospherically struck, and the depths of their respective impressions. A Crimean medal, for example, demands a heavy blow perhaps more than one, if the metal be not kind—whilst a sixpence requires but a light touch to give it head and tail. The amount of pressure employed in these and all intermediate cases is indicated on a graduated mercurial gauge. Thus, it will be seen, that an easily governed vacuum—the first and principal step towards atmospheric money making
—has been gained. Along the top of the vacuum chamber, and supported by pipes opening into it, are eight open topped cylinders of 12in. diameter. These stand vertically, and working in each there is a leather-packed piston. The pistons are the media upon which the atmosphere will, at the proper moment, act, that is, when pneu-matic valves below them open into the vacuum chamber. The air within the cylinders then rushes down to the exhausted tube, the atmospheric column drives the pistons after it to the bottom of the cylinders, and the pistons, being connected with the striking screws of the presses, bring them forcibly in the same direction. At the same instant, and by the same subtle and invisible, yet powerful, agency—the air—the dies are made to compress softened discs of metal between them, fasting impressions are communicated, and money is made. The press-screws rebound, carrying up the pistons, the pneumatic valves are forced open by springs, the pistons again fall, the dies descend upon new blanks supplied to them by mechanical fingers, and another batch of sovereigns—it may be—is literally pumped into existence, owing thus their lives and attractive features to wondrous power of the air.

# VELOCIPEDES.

THE world at the present moment is in a state of considerable excitement, the cause of which is the revival of an old method of locomotion—that by means of the velocipede. Paragraphs have of late appeared in our columns, from time to time, touching upon new phases of the question. But as there has hitherto been more of sensation than of science in it, we have not thought fit to trouble our readers with particulars, which they could glean from the daily papers or even from the posters about the London hoardings. As, board carrying a seat, properly balanced and however, we have had enquiries of late from two somewhat remote districts, we purpose this seat, a bar passed obliquely downward; Some manufacturers have large places in saying a few words on the subject, for the at the end of these bars, a wheel was placed which purchasers are instructed in the

VELOCIPEDES. MODERN

edification of those who may not have posted themselves in the most recent practice of the velocipede. The past history of the question will be found in our volumes, or may be traced by the aid of the Patent Office specifications. The original inventor of the velocipede appears to have been M. Niepce, as shown by some letters written by his brother in 1818 and 1819, extracts from which have appeared in the "Moniteur de la Photographie." Our volume for 1831, contains a letter over the signature of "Saxula," proposing that a man should wheel himself up an incline in a wheelbarrow without touching the ground. In 1824, a Mr. Jameson described in our columns a velocipede, constructed similarly to a Bath chair. This arrangement—the tricycle, as it is termed—is not, however, so safe as the four-wheel system, which has generally been adopted until lately. The two-wheeled veloadopted until lately. The two-wheeled velo-cipede, or bicycle, is not an entirely new idea. Nearly forty years since, one was described, which was moved by means of a large screw connected to various cogged wheels, set in motion by the rider turning a handle. The carriage itself was of a peculiar construction, there were only two wheels, one before and one behind; but at each side were four iron rods, with small wheels attached to the ends.
In Volume XXXIV. of the MECHANICS'

MAGAZINE for 1841, is a letter, which states that the first velocipede was introduced in France ("L'Historie se repete"). This velocipede ("L'Historie se repete"). This velocipede consisted of two wheels, about 21ft. or 3ft. in diameter, connected by a pole, one wheel being in front and the other behind; the rider sat on a seat across the pole, and propelled himself by striking the ground afternately with his feet. The second made, consisted of two wheels, 5ft. or 6ft. in diameter, between which the rider balanced himself on a seat, propelled as before. A velocipede, coming nearer to the one now in use, is also described in the same volume. It is a velo-cipede which had two wheels of about 6ft. in diameter, of the lightest construction, placed 3ft. or 4ft. apart, and connected by an axle-

12in. or 18in. in diameter. The wheel reached within 6in. or 8in. of the ground, and the rider had two stilts, made of bamboo or other light material 18in. to 30in. below the feet, provided with flat stirrups to support his feet. Velocipedes of many kinds have his feet. Velocipedes of many killed been invented and constructed at various times, although the safe four-wheeler has been the form most generally used. The bicycle is the style now adopted, no one condescending to mount a machine which does not tax the skill and dexterity of the trundler. Besides, a bicycle, well managed, has a far more graceful appearance than is presented by the other forms. Such is the rage for these machines at the present time, that manufactories for their production, and schools for teaching their use, are being established in all directions.

The accompanying engravings show the construction of two forms of the modern bicycle, or two-wheeled velocipede. represents a front view, and fig. 2 a side elevation, of a bicycle with a self-brake, actuated by the handle in front of the rider, and by which he has the power of stopping instantly; fig. 3 is another form of velocipede. Each example is very light, and of elegant construction. We have selected elegant construction. We have selected these from a number, which are manufactured by Mr. A. Davis, of No. 14, Strand. Mr. Davis has also written a little pamphlet, giving the history of the vehicle, and tracing it through its various modifications, from the earliest time down to the present. pamphlet will be found both interesting and instructive, as it gives directions for the use of the velocipede. With regard to the velocipede question in France, Mr. Davis observes that manufactories have been established on a large scale in Paris elsewhere, and the new carriages are constructed on very scientific principles—light and elegant, with all kinds of delicate appliances. They are generally made with only two wheels (bicycles), while those constructed with three wheels are called tricycles. The word velocited being the tricycles. The word velocipede being too long, it has been abbreviated to velox.

Digitized by GOGLE

management of their carriages, and three or four lessons are said to be sufficient to form competent velocipedists. Many young men have adopted them, and in the country the velox may be seen awaiting its master at the railway station. In one case, an economical application has been made of the tricycle, the rural postmen of the department of the Aube being provided with them, and considerable time is thereby saved in the delivery of letters in consequence. A box is attached to the machine in which the postmen are allowed to carry parcels for customers, so that a regular parcels delivery is established in the district, and the charge for the parcels soon pays for the velocipede. The spider-like structure of the velocipede makes it very dangerous to pedestrians at night, and those in Paris are now provided with a small lantern to prevent accidents.

From our neighbours across the Channel the furore migrated to our brethren across the Atlantic, passing over us. The go-ahead vehicle is exactly suited to American ideas. Walking, say the New York wags, is on its its last legs. Schools, with the imposing name of "Velocinasiums," for teaching the young idea how to gyrate, are being established; races are being rolled; men and boys are being whirled here, there, and everywhere at the speed of twelve miles an hour. Inventors are improving the machines, and manufacturers are making them wholesale, the supply at present falling short of the de-Our turn has come, and, after a lapse of thirty years, we find the velocipede mania revived. The advantages of this system of locomotion are considerable; we are entirely independent of exterior aid in propelling our-selves, and while we, indeed, in doing work, consume a certain amount of energy, we have the satisfaction of replacing that in the desirable shape of food. The velocipede eats nothing, costs nothing to preserve it in working order, requires no extra attention or looking after, and is ready for our pleasure or necessities at a moment's notice, so that, in proper hands, it is a safe and convenient method of personal transport.

# ROYAL INSTITUTION.

ON Saturday afternoon, April 10, Mr. Archibald Geikie, F.R.S., director of the geological survey of Scotland, lectured upon the origin of land surfaces. The next Saturday he gave a second lecture on the same subject. He principally devoted his attention to denudation, or the wearing down of hills and valleys by the action of water. He said that water acts more rapidly in changing the external features of a country than is commonly supposed, and gave the best evidence to be had, tending towards the conclusion that in one million years—a very short time in geological science—the present action of rain and rivers is competent to scoop out a valley of very considerable dimensions. He narrated how the freezing of water in the cracks of cliffs gradually detaches large fragments of rock from the main body, and he explained that springs of water escaping from the middle of a cliff tend to undermine and overthrow superincumbent strata. Lastly, he called attention to the action of glaciers in the formation of undulating land surfaces, for these vast masses of ice rub down the uneven surfaces of the land over which they travel, and polish their paths to some extent by means of stones and mud.

On Tuesday, April 13, Professor Grant F.R.S., gave a second lecture upon the fixed stars. In this lecture he described their apparent motions through the heavens, and gave the following figures as to the relative brightness of those whose light has been measured photometrically:—Sirius 1,000, Alpha Lyrs 617, Alpha Aquils 450, Procyon 445, Rigel 439, Alpha Orionis 411, Alpha and showing that the centres of spherical tion with a spiritual world, by means of raps.

Virginis 310, Aldebaran 220. In calling lenses bring objects to a focus at a further table motions, trances, and other phenomena.

attention to the phenomena of coloured stars, he remarked that when double stars are coloured, say green and red, the inhabitants of worlds revolving round such suns must have rather a peculiar time of it, for they must have a green day or a red day, according to which sun chances to be above the horizon at the time. When speaking of the fact that the fixed stars are suns, he narrated how an Italian astronomer once suggested the same thing, and for expressing an opinion so full of heresy, he was tied to a stake and roasted alive by the church. On Thursday, April 15, Professor Tyndall, LL.D., lectured for the second time upon "Light." This lecture also was of an elementary character, and explained the laws which govern the reflection of light from concave and convex mirrors, also the laws of the refraction of light by transparent media and lenses. When an inverted image of an object is cast upon a screen by a lens, it is possible to reverse the image and bring it upright by the intervention of a rightangled isosceles prism, which is a fact worth knowing by those who use magic lanterns. The lecturer illustrated this experimentally. In explaining the cause of the whiteness of the foam of the sea, Professor Tyndall said that in the passage from one medium to another of a different refractive index, light is always reflected; and this reflection may be so often repeated as to render the mixture of two transparent substances practically impervious to light. It is the frequency of the reflections at the limiting surfaces of air and water that renders foam opaque. The blackest clouds owe their gloom to this repeated reflection, which diminishes their transmitted light. Hence also their whiteness by reflected light. To a similar cause is due the whiteness and imperviousness of common salt, and of transparent bodies generally when crushed to powder. The individual particles transmit light freely; but the reflections at their surfaces are so numerous that the light is wasted in echoes before it can reach to any depth in the powder. The whiteness and opacity of writing paper are due mainly to the same cause. It is a web of transparent fibres, not in optical contact, which intercept the light by repeatedly reflecting it. But if the inter-stices of the fibres be filled by a body of the same refractive index as the fibres themselves, the reflection at their limiting surfaces is destroyed, and the paper is rendered transparent. This is the philosophy of the tracing paper used by engineers. It is saturated with some kind of oil, the lines of maps and drawings being easily copied through it afterwards. Water augments the transparency of paper, as it darkens a white towel; but its refractive index is too low to confer on either any high degree of transparency. It, however, renders certain minerals, which are opaque when dry, translucent.
Mr. W. Carruthers, F.L.S., of the British

Museum, lectured on Friday, April 16, upon "The Cryptogamic Forests of the Coal Period." In the lecture, he confined all his remarks to a very technical botanical de-scription of the several parts of one or two tree ferns, and afterwards drew the conclusion that two of them, from 30ft. to 60ft. high, are represented in our present vegetation only by our common horsetail and lycopodium.

On Tuesday, April 20, Professor Grant, F.R.S., delivered his third lecture upon "Stellar Astronomy," and spoke chiefly of temporary and variable stars. He showed that the fact of the temporary character of some stars has been thoroughly authenticated, and he said that the number of stars which are known to vary regularly and periodically in brightness, now exceeds 100. There are also a few irregularly variable stars.

On the following Thursday, Professor John Tyndall, LL.D., gave his third lecture upon "Light." After explaining the refracting properties of lenses of different shapes, and showing that the centres of spherical

distance than the outer portions of the same lenses, so as not to throw a perfect image, he exhibited two dioptric pieces of apparatus lent him from Trinity House. One of them was the lantern used with the electric light at Dungeness, and consisted of a bent cylindrical plane convex lens round the source of light, and an arrangement of bent prisms above and below this lens, so that the light, after falling upon one surface of the prisms at the angle of total reflection, is thrown out in a horizontal direction. All lighthouse appa-ratus is constructed on this principle. The other lantern showed the method of producing revolving lights. Much of this lecture was occupied in the explanation of the optics of the human eye. Every eye has a blind spot where the optic nerve enters the eye, and the presence of this blind spot may be made evident by the following experiment:two black wafers or large spots of ink three inches apart upon a sheet of white paper, and place the left eye vertically about a foot above the right-hand wafer; then close the right eye, and while looking at the right-hand wafer, the left-hand one will be invisible, because its image falls upon the blind part of the retina. Professor Tyndall also said that almost every eye contains bodies more or less opaque distributed through its humours. The so-called musco volitantes are of this racter; so are the black dots, snake-like lines, beads, and rings, which are strikingly visible in many eyes. Were the area of the pupil contracted to a point, such bodies might produce considerable annoyance; but because of the width of the pupil, the shadows which these small bodies would otherwise cast upon the retina are practically obliterated, except when they are very close to the back of the eye. It is only necessary to look at the firmament through a pinhole to give these shadows greater definition upon the retina. The veins and arteries of the retina itself also cast their shadows upon its posterior surface; but the shaded spaces soon become so sensitive to light as to compensate for the defect of light falling upon them. Hence, under ordinary circumstances, the shadows are not seen. But, if the shadows be transported to a less sensitive portion of the retina, the image of the vessels becomes distinctly visible. The best mode of obtaining the transference of the shadow is to concentrate in a dark room, by means of a pocket lens of short focus, a small image of the sun or of the electric light upon the white of the eye. Care must be taken not to send the beam through the pupil. When the small lens is caused to move to and fro, the shadows are caused to travel over different portions of the retina, and a perfectly defined image of the veins and arteries is seen projected in the darkness in front of the eye. Looking into a dark space, and moving a candle at the same time to and fro beside the eye, so that the rays enter the pupil very obliquely, the snadow of the retinal vessels is also obtained. In some eyes the suddenness and vigour with which the spectral image displays itself are extraordinary; others find it difficult to obtain the effect. Finally, a delicate image of the vessels may be obtained by looking through a pinhole at the bright sky, and moving the aperture to and fro. He closed this lecture with the beautiful experiment known as Duboscq's electrical fountain, wherein the interior of a jet of water is brilliantly illuminated by rays from the electric light, and is made to take varying colours by the interposition of coloured

On Friday, April 23, Mr. E. B. Tylor lectured upon "The Survival of Savage Thought in Modern Civilization." He said that he intended to call attention principally to the great spiritualistic movement at present going on in England and America, the promoters of which teach direct communica-tion with a spiritual world, by means of raps.

He pointed out that savages almost all over the world hold the belief that it is possible for certain individuals in their tribes to become insensible, leave the body, enter the spiritual world, and come back to tell what they have seen, like Swedenborg; in fact, he said, the man goes mad and sees visions. After nar-rating that the untying, by spirits, of persons bound with ropes is known both in Greenland and Siberia, he pointed out that obtaining communications by writing has long been known to the Chinese. Rapping spirits were common in the middle ages, and "knockers" are known to the Welsh miners. The records of the doings of the early Christian saints swarm with accounts of the raising of the human body in the aira pastime in which one of the archbishops rejoiced exceedingly, and the mantle of that archbishop, said the lecturer, has evidently descended upon Mr. Home. The modern medium, he said, is nothing but a "medicine man in a dress coat." After lecturing for half-an-hour upon the alleged facts of the spiritualists, he said that he had never been to see any of them himself. He did not say that the facts were not real, but that the doctrine that they originate with spirits belongs to savages. In the course of his remarks he said that the custom in European and English churches of worshipping with the face to the east is of savage origin. The allegation that churches are so arranged because the east is the direction of Jerusalem is incorrect, because churches on the other side of Jerusalem all point steadily to the east.

On Saturday, April 24, Mr. Archibald Geikie, F.R.S., delivered the last of his lectures on the "Origin of Land Surfaces."

# THE INSTITUTION OF NAVAL ARCHITECTS.

THE last of the papers which were read at the meetings of this Institution was one by Mr. Charles H. Haswell, of New York, the title of which was "The Location of Independent Steam, Fire and Bilge Pumps in Steamers." The object of this paper was to The object of this paper was to point out the great dangers to a ship, arising from the fact that the pumps and the engines which work them are generally situate in the hold. It certainly is a surprising fact, that the pumps, on which the safety of the ship, in many cases, entirely depends, should be placed in the one of all places where they are the most difficult of access, and the soonest rendered perfectly useless when the ship is in a leaky state. Mr. Haswell contends most reasonably that the pumps and all their necessary concomitants should be placed where they can be most readily reached, and where they can be used for the longest period without being submerged, enveloped in smoke, or cut off by fire. He mentions three several vessels, the "Arctic," "Austria," and vessels, the "Arctic," "Austria," and "Britannia," all of which he believes to have been lost from the bad arrangement of their auxiliary engines. The remedy Mr. Haswell proposes, is, in his own words, "to require this pump to be located upon the main or tonnage deck, and that it have an independent boiler attached to it, located upon the main deck, or, preferably, upon the spar deck, in vessels having two or more decks; and that all passenger steamers be required to have this boiler ready for operation during the principle of the present of the prese the night or during the prevalence of a fog.

There were two other papers, which were sent in to be read at the meetings, but which were too late to be put in the ordinary list. They were merely taken as read. The first of these was by Mr. W. F. Reynolds, "On an Instrument for Determining the Deviation of Ships' Compasses"; and the second by Mr. J. S. Holland, "On Horse Power." Mr. Reynolds described an instrument, to which he has given the name of Palinurus. It is to be hoped that the ill fate of the gentleman from

whom the name is taken will not attend any helmsman, who may be enterprising enough to try the virtue of the instrument. The object that this instrument is designed to fulfil is "the production of a simple tool, capable of being readily understood, and easily used by an ordinary mariner, without reference to any abstruse calculations, and which is as reliable and perfect in the practical results of its operation as are the methods and formulæ of the mathematical navigator." We are afraid that Mr. Reynolds will not be so successful with his machine as he is sanguine enough to hope. Mr. Archibald Smith and Captain Evans would, no doubt, be among the first to rejoice in any plan which would render all their abstruse calculations unnecessary, and we should hail with delight any method which would get rid of the immense uncertainty which now attaches to the use of the magnet in iron ships. We, however, do not think that this object is to be attained so easily.

Mr. Holland's paper was an indignant protest against the use of the—we may almost say obsolete—nominal horse power. Why, he asks, should not engineers be allowed "the privilege of calling a spade a spade," and so be put on an equality with shipbuilders, who, Mr. Holland thinks, are allowed to call everything by its right name. We cannot entirely sympathise with this gentleman in his complaint. The word "ton" is in use in more senses than one in the shipbuilding world. We do not know that this tends to fraud or misrepresentation. If it does, an alteration should certainly be made without delay. So the use of nominal horse power, if it really does mislead even the average ignoramus who gives an order for an engine, should be discontinued. We do not think it does.

We have now given our readers a general resumé of all the papers which were read at the meetings of this Institution. We are sorry that once a year we are compelled to give our readers a surfeit of naval architecture and all its attendants. We really cannot avoid it. The naval architects meet but once a year. They are like the members of the British Association—dis-They are like the persed over the length and breadth of the land, and are not easily collected. We should be glad, for the interest of the Institution and for the benefit of the nation, to see some scheme proposed whereby all the points which interest a naval architect or a marine engineer would be brought to the notice of all the members of the two professions from time to time, as they arise. If, however, unavoidable difficulties attend this, we must be satisfied with the over-abundant harvest when it comes.

# BRONZE STATUE OF HER MAJESTY FOR MONTREAL.

A FEW weeks back we had occasion, in mentioning the casting of the statue of Lord Palmerston at Messrs. Holbrook and Co's works at Chelsea, to speak of a statue of Her Majesty for Montreal, Canada, the moulding of which was then rapidly approaching completion. We are now glad to record the successful completion of the work. This colossal figure, which is 10ft. high, independent of pedestal, has been cast in Florentine bronze metal, the proportions of which are:—copper 45, fine yellow brass 50, tin 4, and antimony 1. The effect of this mixture is a rosy tinged yellow metal, capable of taking a brilliant polish, and approaching, when polished, the lustrous purity of silver. It is a matter for regret that this beautiful composite metal is unsuitable for the embellishment of our metropolis. It, however, contains a greater proportion of alloy than the ordinary statue bronze, and this renders it more susceptible of oxidation. When

London atmosphere it would speedily show the progress of decay; besides, its purity and delicacy of colour effectually prevent it from occupying a prominent position in the London streets; every speck of soot would be plainly obtrusive to the eye, and the beauty of the material would be detrimental to its credit. We congratulate the inhabitants of Montreal upon the possession of a climate in which such a material may be exposed in the open air without any injurious effect.

The honour of the design is due to Mr. Marshall Wood, the sculptor. He has shown the Queen in an erect and commanding position, crowned and clothed in a classic manner. Her Majesty's countenance is a fine representation of the typical English woman; she bears in her hand a wreath of oak leaves and acorns. Very great difficulty was experienced in forming this part of the mould, owing to the intricacy of the foliage and complication in the mould which it entailed; but by dint of skill and perseverance, the mould was formed, so as to allow the figure to be cast in one piece. We have before had occasion to point out how much the success of the statue depends upon this. The running of this casting impressed one with the necessity of having powerful machinery in prosecuting this branch of industry. A huge cauldron, containing upwards of three tons of the molten bronze metal, was carried, without the slightest difficulty or apparent risk, from the furnace to the mould, by the traveller, and the contents deposited in a trough, from which, by numerous inlets, the metal was admitted to the mould. Although the actual weight of the statue will not exceed two tons, the surplus metal is provided for the purpose of forming a head above the casting, to act as a weight, in order to render the metal more dense, and to force it into the smaller crevices of the mould. From the present stage the statue will proceed to completion, under the immediate superintendence of Mr. Wood. However skilfully the model may have been formed, the chisellers must proceed under the direction of the artist.

Much of the success of bronze casting, as regards accuracy of the figure, depends upon the care with which the proportions of the alloys are chosen. It is a rule applicable to all alloys that thorough combination will only take place when the ingredients bear a definite atomic proportion to each other. Unless this is observed, the metal is not homogeneous, but consists of a number of varying compounds irregularly dispersed through the mass, which, when broken, will show a mottled appearance. The difference in the expansibility and elasticity of these compounds tends to cause the separation of the parts, and in time will produce a fracture. It is worthy of remark that the bronze manufacture has been for some years very much on the increase in England. This branch of industry is so nearly allied to the fine arts, that it affords a fair standard of the advancement of taste and spread of education. Mr. George Wallis, in a very able report on bronze in the Paris International Exhibition of 1867, says, "The conditions necessary for this branch of industry appear to be a knowledge of design and a love of art fairly spread through the people, partaking so largely of the highest elements of design, and depending for its success upon its relations with the art of sculpture in its best and most enduring forms. We can only consider the manufacture of bronzes a trade, so far as the power of reproduction and facilities of repetition will admit."

is a rosy tinged yellow metal, capable of taking a brilliant polish, and approaching, when polished, the lustrous purity of silver. It is a matter for regret that this beautiful composite metal is unsuitable for the embellishment of our metropolis. It, however, that the amount of bronzes exported from France has of late years very much declined. The following statistics by contains a greater proportion of alloy than the ordinary statue bronze, and this renders it more susceptible of oxidation. When exposed to the destructive influence of a

respectively, 44,000,000 francs, 40,000,000 francs, and 34,000,000 francs, thus showing a decrease of 10,000,000 francs in exports, and this he ascribes to competition of England, Prussia and Belgium. Very great pains have been taken in France to provide proper education for the workers in this branch of industry. So far back as 1840 we find Government schools for those engaged in the bronze manufacture. In these schools nothing was taught but what applied directly to the subject. On the schools being given up by the Government, the leading men of the industry formed themselves into an association, and continued to supply a fund to be distributed in prizes among the workmen of Paris. In fact, excellence in this manufacture appears to have been forced upon the workers rather than to have been the spontaneous consequence of the question of taste. It is a noteworthy circumstance that in the early part of the present century the bronze workers of Paris were so ignorant of the laws which affect alloys, that while some parts of the Vendome column contain proportions of 94 parts of copper to 6 of tin, other parts contain 99 4-5ths. copper, and alloy 1-5th. These defective proportions caused bad castings, so that the chisellers had to cut away 70 tons of protuberance on this one monument. Science in the present day is rather in advance of this, and although mistakes are sometimes made, they are not quite so gross as the above. In the statue of Her Majesty under notice, Messrs. Holbrook have adopted very excellent proportions for effect in such a climate as that of Montreal, and have achieved a second and important success in this special department of practical art.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

PHOTOGRAPHIC PICTURES TO REPRESENT MACHINERY IN MOTION-NEW MODE OF BURNING GAS-INTERESTING CHEMICAL DISCOVERY-THE PARIS EXPLOSION.

THE magic lantern with photographic pictures is coming more and more into use in illustrating lectures on all sorts of subjects. Photography is also extensively applied to the delineation of machinery. It has, however, hitherto shared the common defect of all drawings of being unable to give a representation of the machinery in motion; for "painting, mute and motionless, steals but a glance of time." Hence, the necessity for working models for the perfect illustration of mechanical contrivances. According to M. Bourbouze, however, he has partially, at all events, removed the disability under which the photographic art labours, of being unable to give a representation of a machine in motion. To illustrate Hugon's gas engine, for example, he takes separate pictures of the movable parts and another picture of the fixed parts. He then arranges the movable parts on cranks, the lengths of these cranks being calculated so as to show the proper motions and due proportions of the parts; and the whole system is set in motion by a winch and handle. Excepting, perhaps, some difficulty in gotting all the pictures into one focus, nothing possibly stands in the way of exhibiting representations of the kind magnified on a screen, and the use of the art in teaching mechanics will be obvious. We have in England some enterprising producers of photographic pictures for the magic lantern: perhaps they will try their hands on such slides as M. Bourbouze says he can produce.

The same ingenious gentleman, in conjunction with an engineer, M. Wiessneg, has another invention, or, rather, improvement, for we described the original idea more than a year ago. Then it was proposed to place a cylinder of magnesia on a sort of Bunsen's burner, and the incandescence of the magnesia, produced by the heat of the com-bustion of gas and air, was said to give more light than would be given by burning the gas in the ordinary way. It did not, however. Now, the inventors named above compress the gas—to what extent is not said. The compressed gas entering a tube mixes with air, and at the top of the tube (or Bunsen's burner, as we may call it), is a crown or button of magnesia projecting a little over, many hon members connected with the north of them, which ended in the wreck of one of her and enveloped in a platinum gauze, se arranged England, who are interested in this question, will Majesty's ships. An officer connected with her

that the combustion of the mixture takes place between the gauze and the magnesia. The gauze quickly becomes white hot, and together with the incandescence of the magnesia, exhibits an extraordinary amount of light. In fact, they an extraordinary amount of light. In fact, they tell us that a quantity of gas, which, consumed in the ordinary way, will give the light of three Bengel burners, will, when burnt in the way we have shortly described, show as much light as six burners of the same kind. Compressed gas in towns is of course out of the question; gas companies lose too much by the compression which gas is of necessity subjected to in their mains But if we can depend upon the results of MM. Bourbonzo and Wiessneg, it may offer a new class of consumers to gas companies. We well remember the day when compressed gas was sent all over the country. It was oil gas of much higher illuminating power than common coal gas; but if ordinary gas can be made portable, and to yield this increased amount of light, country gentlemen far removed from gas pipes, may light up their drawing-rooms more economically and brilliantly than by the means at present at their command.

We may briefly notice one very interesting chemical discovery. M. Fridal, who has done so much to show the close alliances which exist between carbon and silicium, has, in conjunction with Ladenburg, produced a compound which may be called an oxalic acid in which the carbon is replaced by silicium.

A last word on the Paris explosion. The Commission d'Hygiene et Salubrité, charged by the French Government to investigate the causes of the explosion, has separated without settling precisely what the cause was. It is probable that the Government is unwilling to let the world into the secret of its preparations. The French scientific journal, "Cosmos," however, states, what was at once guessed by all acquainted with the compounds, that the picrate of potash was probably mixed with chlorate of potash.

# PARLIAMENTARY NOTES.

YESTERDAY week, the question of the use of North Country coal in the Navy was touched upon by Mr. Vivian, who asked the First Lord of the Admiralty whether it was a fact that a decision had recently been come to by the Admiralty with reference to the use of North Country coal on board her Majesty's ships; and, if so, whether he had any objection to state what that decision was.

Mr. Childors said that in 1857, in consequence of a report from the West Coast of Africa station, in which the capture of a slaver was attributed to the use of smokeless coal, an order was given directing the disuse of bituminous coal for the present in any of her Majesty's ships. has now been carefully reconsidered and modified to a certain extent, and directions have been given, under which a certain admixture of coal, consisting of two-thirds Welsh and one-third North Country coal, will be used in her Majesty's ships, except on the China and West Coast Africa stations. Orders have also been given for the necessary changes in the furnaces.

At the same sitting, the overland route to Western China was discussed. Colonel Gray asked the Under Secretary of State for India if any, and what, stops were being taken by her Majesty's Government to promote the communication be-tween Rangoon and Western China through a portion of the Shan States; and if the survey of that

route was being proceeded with.

Mr. G. Duff said—Nothing further has been done with regard to promoting communication between Rangoon and Westorn China since the survey was discontinued, in 1867, after it had been carried on for 245 miles, nearly to the extreme boundary our territory. I hope the government of India will see its way to renew the unfinished work. If will see its way to renew the unfinished work. If it does so we shall be glad. But, at the same time, the Secretary of State for India would not dream of pressing the government of India to continue that survey if they were deliberately of opinion that by doing so they would be involved in grave political complications or incur any very great expense. The whole question of communication between India and Western China, of which the project for a communication through which the project for a communication through the Shan States is merely a fragment, and not a very large fragment, is one of very great interest; but it will, I think, become of greater practical importance to the next generation than to ours. But, interesting as it may be, and important as it may become, I think that the hon. gentleman, and

admit that in the Chinese peninsula, as in Abys-

sinia, we may possibly buy gold too dear.
On Friday night, Sir H. Croft asked the President of the Board of Trade whether the words "sea fishing boat," in the Sea Fishery Act, 31st and 32nd Vict., c. 45, were intended to apply to vachts which may occasionally be used in fishing. He desired to include in the question small pleasure boats for hire also.

Mr. Bright said the Board of Trade was not in a position to place an authoritative construction upon the words of the Act of Parliament, but he might tell the hon. baronet that it was not their opinion that these pleasure vessels were intended to be included. At this moment it was under consideration whether something should not be done expressly to exclude them, either by an Act of Parliament or by an order in council. He could not give any answer more definite, but he hoped that would be sufficient to relieve those who feared they might be put to inconvenience by the clause as it now stood

After this, Sir J. Hay followed with a question respecting the rule of the road at sea. He asked the President of the Board of Trade when the remainder of the correspondence on this subject would be laid on the table; and whether he would agree to a motion for the appointment of a committee of the House to inquire into the causes of the loss of life and property at sea by collisions, and as to the possibility of a remedy by some modification of the existing rules of the road, so as to bring them into harmony with the custom of the sea and the decisions of the courts of law.

Mr. Bright was not aware of any correspondence upon the subject that it would be advantageous to lay before Parliament. With regard to the committee, he thought the House would agree with him that its appointment would only disturb a question which appeared on the whole to be satisfactorily settled. When the hon, baronet himself was at the Admiralty, the Admiralty concurred in the arrangements which now existed; and if the committee were appointed it would be to disturb that which all other maritime nations in conjunction with this country had agreed to admit as settled, and, therefore, it was not the intention of the Board of Trade to recommend, nor would they be willing to consent to the appointment of any committee on the subject. With regard to the decision of the courts of law, he presumed that those courts would be obliged to give their decision in accordance with the Acts of Parliament, or with the order of council, which on that matter, he believed, had the same effect as an Act of Parliament.

Last Monday evening, the irrepressible and never-to-be-got-rid-of matter of the Banda and Kirwee prize money cropped up again. Mr. O'Reilly asked the Secretary of State for War if he could state why seven men of the 5th Battery, 17th Brigade, Royal Artillery (formerly A Company, 4th Battalien, Madras Artillery), now stationed at Dover Castle, who where entitled to a share of the Banda and Kirwee prize money, had not yet received it.

Mr. Grant Duff said the delay had occurred because the Indian Government were assured by the Government of Madras that this money had been paid in India to the officer commanding the battery to which these men belong. There was, however, evidently some mistake, as that officer said he never received it. The Government of Madras had been asked to make a strict investigation into the facts, and he trusted soon to have the mistake set right. Always mistakes and delays, unfortunately, on the wrong side for the hoping recipients of this dilatory cash.

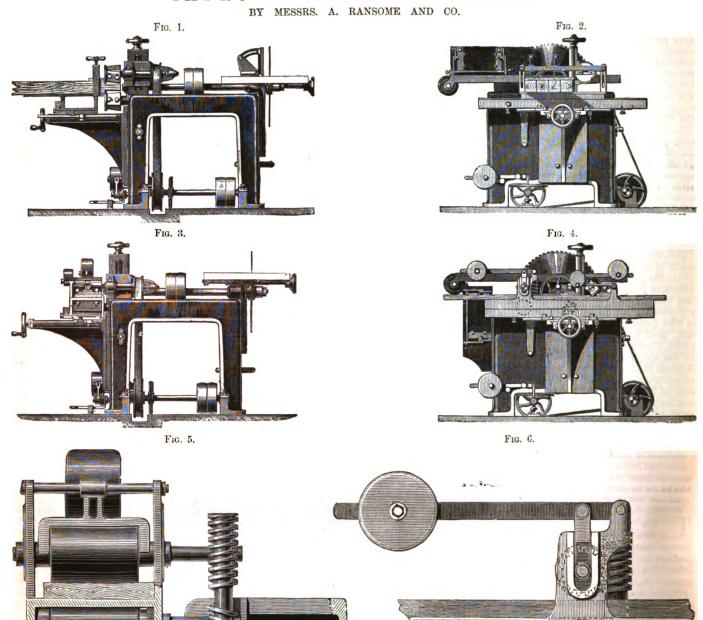

At the same sitting, Mr. Shaw asked the Sccretary of State for War whether the rumoured purchase of Dover House by her Majesty's Government was correct; and, if so, what were the objects for which such purchase had been made.

Mr. Cardwell said it was not true that the lease of Dover House had been purchased by the Crown. But, on the matter to which he understood his hon, friend's question pointed, he had to say that the best mode of placing the War Department and the Horse Guards under the same roof was now under the careful consideration of the Government.

Major Dickson asked the First Lord of the Admiralty if instructions had been given by the Admiralty for the Government moorings in Dover Bay to be examined; and, if so, by whom the duty would be performed.

Mr. Childers said there were two moorings in Dovor Harbour. As the House was aware, on Easter Monday an accident happened to one of

#### IMPROVED GENERAL JOINER.

Majesty's dockyards had been sent down to repair the broken mooring, and the other would

repair the broken mooring, and the other would be examined at the same time.

Mr. Eastwick asked the Postmaster General whether the Bremen Company had made arrange-ments with the Post Office to land the mails from New York at Plymouth. To this the Marquis of Hartington said that the arrangements for the postage of these vessels, including the landing of the mails, was made by the United States Govern-ment, and the Government had not received any intimation of the intention of that Government to

land the mails at Plymouth.

Alderman Lawrence asked the Secretary of State for War whether the expense of twelve or State for War whether the expense of twelve or fifteen hundred pounds a year incurred for storing saltpetre in the docks and private warehouses might not be saved by storing the same in the Government depôts. And, whether he would state what quantity of saltpetre belonging to the Government was at present stored in the docks and private warehouses. Mr. Cardwell agreed

that this would be a judicious piece of economy—so judicious, indeed, that the stores of saltpetre were now in course of removal as his hon. friend suggested, and were now almost all removed.

On Tuesday, Mr. Childers stated that the works at Malta harbour were now nearly completed. He was happy to state that he had been in communi-cation with the Secretary of State for the Colo-nies and the Secretary of State for War, and that they were in a position to send out to the governor of Malta instructions based upon an arrangement which he hoped would preve satisfactory, and would put an end to all the dissensions that had taken place on the subject. By this arrangement the great harbour would be available for merhapt ships and the Transle Coale for the Martin and the Transle for the Martin and the Martin chant ships and the French Creek for her Majesty's

At the same sitting, Mr. Trevelyan moved for and obtained leave to introduce a bill to make better provision respecting Greenwich Hospital, and the application of its revenues, by further ex-tending the system of out-pensions, which had

been found to work well since the changes in 1865. With this view he proposed that only those who required the shelter of an infirmary should be inpensioners, and these should be removed to Haslar and other hospitals, where they would be main-tained out of the funds of the hospital. The tained out of the runds of the hospital. The building now used as an infirmary would be handed over to the trustees of the Dreadnought Hospital; but it had not yet been determined by the Government what use the large structure of Inigo Jones and his successors facing the river should be applied to. Another important part of the scheme was to take out of the workhouses all seamen who had been engaged in the service of the country, and provide for them by small pen-sions out of the funds of the hospital, so that they might be placed beyond the reach of poverty. It was also proposed to pay £4,000 a year to the Board of Trade for division amongst those merchant seamen who might have contributed their monthly sixpence for ten years and upwards to the hospital fund.

### RANSOME'S GENERAL JOINER.

THE compound machine known as the general joiner is the most useful apparatus of which we know in a builder's shop. Its utility is seen in the fact that no shop of any pretension whatever is now to be found without one. But however perfect these machines may have hitherto been considered, it is quite certain that those in general use are capable of considerable improvement. This was made very clear to us by a recent visit to the works of Messrs. A. Ransome and Co. 304, King's-road, Chelsea, where we found the improved machine represented in the annexed engravings. The chief objection which has hitherto been urged against machines of this class is that when the attendant working at one part of the machine has to stop to adjust or change his cutters, all other operations are suspended. This objection has now ceased to exist, inasmuch as in the apparatus under notice the tenoning, planing, and thicknessing, and moulding operations can be carried on without interfering in any way with those that are done at the sawing end of the machine, such as ripping-out, cross-cutting, squaring-up, tongueing and grooving. Figs. 1 and 2 of our engraving are two views of the machine, as our engraving are two views of the machine, as arranged for ripping out and tenoning. Figs. 8 and 4 show the apparatus as set for cross-cutting and planing or moulding. Figs. 5 and 6 are enlarged details; fig. 5 being a section showing the details of the worm feeder, and fig. 6 being a side elevation of the same part. From these latter views the exceedingly nice arrangement for obtaining vertical motion is seen.

By the aid of these engravings and the following observations, the superiority of this machine will be at once apparent. The tenons are formed at one by means of revolving cutters, which finish them much more accurately than they can be finished where saws are employed for this purpose, as is the case in other machines of this class.

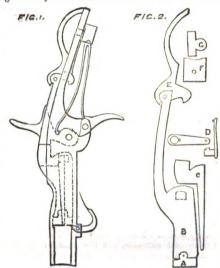

The wood to be tenoned, which may consist of several pieces up to a total width of 18in., is cramped in a horizontal position upon a light sliding plate, instead of each piece being fixed separately in a vertical position, as heretofore. Tenons can be formed with shoulders of unequal lengths, by simply altering the position of one of the tenoning blocks on its spindle. This joiner will plane both sides and thickness, at one operation, boards up to 7in. wide, and will cut single or double moulding of any pattern in any kind of wood, which is quite of any pattern in any kind of wood, which is quite a new feature. The wood being planed is fed through by a pair of revolving feed rollers, both of which are driven, by which means a greatly increased propelling power is obtained, and the rollers, being perfectly smooth, do not indent the wood. In our representation of the machine as arranged for tenoning, the fence is shown at right angles to the table, but it can be readily adjusted to cant at any angle for sawing weather boarding and other bevel work. When the machine is arranged for cross-cutting and planing, the table is raised so as to clear the driving pulleys, the fence being turned over and hanging below the table.

In order to illustrate the practical value of this apparatus, it was set to work and did some moulding and tenoning with such speed, accuracy, and finish, as to place the machine beyond all praise We brought away samples of the work with us, and they are, undoubtedly, the best finished productions of the kind we have ever seen. The topside of the wood was finely moulded, whilst, at the same time, the underside was being planed. In the tenoning, too, a perfect planed tenon was produced at one operation. The advantage of driving both top and bottom rollers cannot be overrated, as in other machines, where the top roller only is driven, it is found necessary to groove it very deeply, in order to give it sufficient propelling power, and thus the board, is, in many cases, very materially injured. It will further be seen, on reference to our detail figures, how the top roller is arranged to rise and fall, so as to suit the irregularities in a rough board; at the same time, it is always exerting its full feeding power. By means of a very simple mechanical arrangement, the rate of feed can at once be varied from 5ft, to 12ft, per minute, whilst the machine is in full work, and the attendant working at this portion of the machine can retard or accelerate the feed, according to the nature of the wood about to pass under the cutters. It may be as well, before concluding, to say a few words respecting the fence. Instead of the long and cumbrous fence, which, in general, is required to carry the tenoning slide, a light fence is substituted, which is arranged to turn over and hang down below the table, thus enabling the machine to be used as a cross-cut saw bench for any length of linear tenoning slide, a light fence is substituted, plied, and tapered into a spring from this shoulder so as to throw the breech plug so far back into its bed as to hold the cartridge in its chamber when laid in Trinity churchyar inserted. Cocking the gun brings all the pieces of side of those of his wife.

stuff, without interfering with the work going on at the other end of the machine. In other joiners, this is impracticable, on account of the difficulty in removing the fence. The operation of changing the machine from one class of work to another is performed in a very short time; in fact, Messrs. Ransome have succeeded in rendering this machine in every respect the most perfect of its kind, and it has afforded us much pleasure to record the successful results of its working.

### THE ROBERTS' BREECH-LOADER.

N the last number of the "American Army and Navy Journal" that has reached us, we find the Anyy Journal that has reached us, we find the following particulars respecting the new breech-loading rifle of General B. S. Roberts, of the United States Army. The principal features of this new arm are nearly identical with his system for the transformation of old muzzle-loading arms into breach loading. The new gun is, more properly speaking, the Roberts system perfected. In making a new gun, the opportunity was offered of applying the mechanical parts of the system, so as to operate the arm with more ease, and to give strength to pieces in a new arrangement that could not, for want of space in the system of transformation, be made of the proportions for necessary solidity and strength for military purposes. General Roberts, as an army officer of nearly two score years' experience, has had unusual opportunities for understanding the kind of arm required for the soldier. He has studied simplicity, solidity, and safety; and has, at the same time, sought to secure the utmost rapidity of fire. He has reduced the operation of loading and firing to four short, quick, and safe motions, and can discharge twenty shots per minute from the shoulder. He has so automatonized the mechanics of his gun that it may almost be said to work it-He has made it so secure against premature discharge, that accidental firing is impossible. He has fewer and stronger pieces than any other breech-loader yet invented. Nine pieces constitute his lock and all the breech-loading plan. Every piece is large and strong, and they work together on articulated joints, avoiding wholly the use of screws and pins, or any other pieces liable to be lost or broken. The plan of the gun is wholly novel-a system of articulated levers, so joined by circular joints as to operate each other, and yet when in position for firing to have all the solidity and strength of a single piece. Fig. 1 of the annexed cut shows the parts assembled whilst in fig. 2 they are seen detached. A is the recoil

plate, B the breech plug, C the firing pin, D the breech plug key, E the lever catch, F the front of the recoil plate, and G a section of same.

Three levers work together, and constitute the entire breech-loading parts. A lever catch holds the lever breech plug in its bed, and is articulated strongly on the rear of the long arm of the plug. The office of this "catch" is to prevent accidental opening of the chamber. Raising it smartly ejects the cartridge shell after firing by a positive strong force taking effect at the short arm of the lever plug. The cartridge ejector is a lever so shaped as to have a strong shoulder, when the force

the breech attachment safely and securely home to their places of firing. The main piece of the breech plug moves in a solid circular shoulder at the base of the barrel, the centre of the shoulder being the exact prolongation of the axis of the gun, so that the force of the gases has no tendency to move the plug out of its solid bed. The front end of this plug, that rests square and solidly against the base of the cartridge, is transversely articulated on the main plug by a circular joint, and has play enough around its transverse axis to allow the plug to fall below the axis of the gun, when the lever is thrown up after firing. Below that axis it draws to the rear, so that the plug has full play from the top of the barrel to the bottom. By this lever system of mechanics all the pieces constituting the breech attachment of this gun are strong and substantial, without a screw or pin, or any small piece to be broken or lost. The articulating plan of joints avoids the use of pins, screws, or any small or weak pieces.

Another advantage of the Roberts gun is that he tapers his chamber its entire length, and manufactures his cartridges with a corresponding taper their entire length. In this way he easily ejects the discharged cartridge shell, and is not delayed in uniform rapidity of fire by the sticking of the discharged cartridge in the chamber. The centrefire cartridge of his system is his own invention, and he has an independent patent both for his car tridges and the machine for tapering them. He uses, too, a new and improved bullet of his own invention, increasing the range, strength, and pre-

cision of fire of this new arm.

Three short and quick motions operate the loading and firing. Throwing up the lever ejects the cartridge shell. Inserting the cartridge and cocking prepares the gun for firing. The gun must be full cocked before the centre firing pin can be brought into place to reach the fulminate. act of cocking the gun, and no other act, can bring the breech plug into its firing position. Premature discharge is impossible. The lock, if lock it ture discharge is impossible. The lock, if lock it can be called, is perhaps the greatest novelty in this arm. It consists of three pieces only, and has neither a screw nor pin to put them together. The cock, the trigger, and a double main-spring of great strength, are the three pieces. The two ends of the double spring are set against and held into the cock and trigger on shoulders, so operating the force of the spring against the cock and trigger that they serve as the "sear" and "tumbler" in the old gun lock. The lock occupies very small space centrally in the rear of the chamber. The cock is slotted through the rear handle of the lever, and its head delivers a strong blow in a direction that forces the firing pin directly forward, insuring unerring certainty of The gun stock is uninterrupted in its entire length, and is in no place weakened by being cut to insert pieces of metal, and has but two screws that penetrate it for any purpose.

# THE INSTITUTION OF CIVIL ENGINEERS.
